Carnations that have been wintered in cold frames, if sufficiently hardened off, may now be planted-out, and any layers that were rooted late may be lifted with a good ball of soil to the roots. Place some maiden loam round the roots, treading it firmly, and protect the plants from cold east winds till fresh roots are made.

The Beds.—Bulbs of Narcissus, Crocus, Tulips, &c., that will be left in the beds after flowering should have a sprinkling of bone-manure or basic slag pricked in with a small fork. This will help to strenthen the flowers, and the growth after flowering.

Violas.—Those which were progagated from slips in a cold frame in the early autumn will have made sturdy plants. and being duly hardened off, they may now be planted out, so as to get them established before the warm weather sets in. In selecting a position for Violas, choose an open one, but not exposed to full sunshine, and afford a dressing of fibrous loam and coarse sand, but avoid manure, as it encourages sappy growth. Let each plant be lifted with a trowel, so as to obtain a ball of earth, and press the soil slightly, so that it may hold together. A distance of 9 inches apart will be sufficient, and all flowers should be kept picked off, and the strong stems pinched-back till the shoots meet and form a tuft; when they may be allowed to flower. Assist them by an occasional application of liquid cow-manure. Be sure to remove all old flowers and seed-pods, or the amount of flowers, and the length of time plants will produce them, will not be satisfactory. Violas are most effective when planted as a groundwork to other plants, such as the variegated Abutilon, and Acer Negundo variegata, small pyramidal plants and standards of these plunged in pots with a groundwork of the rich dark violet-blue of Viola Archibald Grant, make a beautiful contrast. Upright bushes of a dark-flowered Heliotrope and the soft yellow Viola Wonder is an effective mixture; as is Viola Blue Bell with the silver-leaved Pelargoniums planted alternately. The beds of these Violas keep good the whole season. Other good varieties are Bullion, yellow, Countess of Kintore, deep purple; Duchess of Fife, beautiful sulphur, orange-yellow centre, edged violet; Lord Elcho, yellow; Mauve Emperor, beautiful mauve colour, and very free; Marchioness, pure white, yellow eye; Goldfinch, yellow, with purple margin.

Dahlias.—Tubers which have been stored away, should now be started into growth by laying them out on a Peach-house border, or in trays, and covering them with a 6-inch layer of leaf-mould. A temperature of 60° will be sufficient to start them. Let them be kept moist till shoots push through the soil, then take them out, cut away all blind tubers, and divide and pot up, and keep them rather cool to encourage a sturdy growth. Tubers of Salvias may be similarly treated.

Clematis.—These effective climbers may be purchased in pots, and planted at this season. They will grow trained against walls, but few persons care to plant them, owing to the difficulty of fastening the shoots, and their bare appearance during the winter months. Clematises look best when creeping over an old tree or shrub, or trained over a pergola or an arch. They are gross feeders, and should be planted in heavily manured soil, and if naturally devoid of lime, some of it should be added. Train the shoots for the first year, and afterwards they will take care of themselves. Clematis Jackmani, C. J. superba, and C. J. alba are effective plants in beds and to cover arches. These require pruning-back hard this month. Clematis montana looks well if planted so as to creep up among the stems of Wistaria sinensis, and both flowering in May, they form a pleasing contrast. Clematis flammula may be planted against a fence or trained over an arch. It develops a mass of small white, deliciously fragrant flowers in August. C. lanuginosa and the garden hybrids produced from it are very beautiful, producing lovely blooms during the summon months. These varieties flower from the wood made the season previously, and only require thinning and tying-in younger shoots.

Bedding.—Myosotis, Crimson Daisies, Primroses, and other spring bedding plants should have the soil made firm round the roots, and receive a good soaking of manure-water at the roots, as well as a light top-dressing. On dry mornings sprinkle them overhead with clear water in order to hasten growth and bring out the flowers early.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Asparagus.—If much Asparagus is taken up and forced annually, a similar number of plants must be planted each spring to keep up the supply. When Asparagus is grown solely for forcing, it is not essential to prepare the land as for permanent beds, and any piece of land in good heart will do if heavily manured and deeply dug. It is somewhat early as yet to plant, but with mild weather the roots will soon be on the move, when planting may safely be done. Having roughly levelled and raked the surface, trample it all over, and rake finely; then draw with the hoe broad drills, deep and wide enough to allow of the roots being spread out and buried 3 inches deep. The plants should stand 18 inches apart each way. Seed of Asparagus may be sown in shallow drills at this date, the seedlings being thinned when large enough to 8 inches apart, and alternate plants taken up the following spring and transplanted; doing this means a little more labour, but it pays. The germination of the seeds may be forwarded by sowing in boxes under glass, the seed being put in 3 inches apart, and the seedling transplanted with a trowel in the month of May. By thus rearing plants in heat, almost one season's growth is gained. The land for forming permanent beds should be heavily manured with rich decayed farmyard dung and a small quantity of soot, and seaweed if obtainable, and be deeply trenched. On light land, salt forms a valuable addition. If the land is intractable and heavy, plenty of road-scrapings or sea-sand are of great use. The plants should be set out 2 feet apart triangle-fashion, the beds being made sufficiently wide to accommodate three rows. Let stout wooden stumps be firmly driven into the ground at the four corners, and an alley 2 feet wide made between the beds. When the plants are planted, rake the surface smooth, and finish-off in a workman-like manner. Beds in bearing should be marked out anew, and the sides made good with soil from the alleys, and a small quantity thrown on the top; but in doing this, do not dig the alleys so deep as to damage the roots.

Cauliflowers.—Those plants which have wintered under hand-lights, say, six or more under each, should forthwith be reduced to the four at the corners, the supernumeraries being lifted with a trowel and planted elsewhere, affording water so as to settle the soil about them, and protecting them for some time longer with hand-lights, or twigs of Spruce Fir or Laurels stuck in on the north side. Cauliflower plants raised from seed sown last autumn, and wintered in cold frames, should be planted out before they become drawn. Let the spring-raised plants standing in frames be afforded plenty of air in mild weather A few of the Dwarf Erfurt may be planted out at a later date 1 foot apart at the foot of a south wall. If there is likelihood of there being a gap between the late Broccolis and the first batch of Cauliflowers, recently-raised seedlings may be pricked off and grown on under glass for the time being, and be similarly treated to those early sown.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Epacris.—As soon as any of these plants go out of flower, the young wood should be cut back closely, at the same time keeping the house somewhat closer, in order to encourage the formation of new growth. If any of the plants require to be repotted, they should be attended to when the young growth is about half an inch in length, using good fibry peat, broken into small lumps by hand, adding a liberal allowance of sharp silver-sand, and some finely-broken crocks or charcoal. The pots should be quite clean, and if new, they should be soaked for a few minutes in a tub of water the day before they are required for use. Should the peat be dry from being stored under cover, it should be sprinkled with water until sufficiently moist. A shift into pots one size larger is usually sufficient, the compost being filled in gradually, and rammed evenly round the ball with a thin rammer, until it is is as firm as the old ball. Care should be taken not to injure the roots in removing the crocks from the old ball, or by using too large a rammer in potting. Extra care will be required in affording water until the roots take possession of the new soil.

Nerines.—These may be afforded an occasional application of liquid-manure, and a position near the glass fully exposed to the sun in a house where the night temperature is kept at about 50°. No attempt should be made to dry off the bulbs until the foliage begins to turn yellow, when water may be gradually withheld. The plants may then be placed in a cold frame, and kept quite dry and unshaded throughout the summer.

Carnation Seed.—If this is sown at the present time, the seedlings will flower in sixteen months; and if the seed be obtained from a trustworthy source, a considerable variety of colour and form will be found in the seedlings. A certain proportion will produce single flowers, and these may be discarded or not, according to the fancy of the raiser; the remainder will consist of blooms of varying degrees of doubleness, from flowers containing only a few petals to those in which the petals are crowded, and between these two extremes will sometimes be found blooms of considerable merit, which the raiser will desire to propagate. If he is careful to obtain his seed from the best sources, he is sure, with ordinary good luck, to obtain some varieties which he will consider very satisfactory. The seed should be sown in pots or pans filled with light soil, covering the seeds slightly, and placing the pans in an intermediate-house, or plunging in a mild hotbed. The seedlings will appear in a week or ten days, and growing quickly, they are soon strong enough to be pricked out into boxes. When the plants are well established in the boxes, they should be removed to a cold frame, and gradually afforded more air. The subsequent treatment consists in potting the plants into small pots, and later into 5 inch pots, in which size they should be wintered.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq. Dropmore Maidenhead.

Crown or Rind Grafting.—Where orchard-trees of considerable size are to be worked with other varieties, rind-grafting is the best method. Assuming that the crown has been reduced in size, cut the branches back to the desired length. If the tree has ten or twelve main branches, two grafts may be placed on each, and in a few years the tree will come into bearing—that is, if grafting is properly carried out; and it will possess a spread of branches equal to that the tree had originally. The stock may, if so desired, be headed hard back to one main stem, and three grafts be placed on this; but my experience with trees worked as the first-named has been more satisfactory, and a full-sized bearing tree is obtained in less time. The lower end of the scion in this method of grafting is for about 3 inches, cut sloping and slightly hollow, almost similar to the first process for whip-grafting; and in the stock a downward slit is made in the bark to correspond in length to the sloped off part of the scion. The handle of a budding-knife or a smooth piece of wood shaped somewhat to resemble the part of the scion to be inserted, is introduced at the top of the slit, and gently pushed down so as to raise the bark, and when it is removed the scion is pushed down in a similar manner. If a second one is to be inserted, this should be placed on the opposite side, and then both should be bound round with matting, and clayed over in the usual manner (see figs. 64, 69, 70).

Cleft Grafting (fig. 63) is often practised in the West country. In doing it, prepare the stock as for crown-grafting, and with a broad, sharp chisel, split the head of the stock, leaving the instrument in, or using a wooden wedge to keep the split open, to allow of the edges being made smooth, and the scions inserted one on either side. Cut these wedge-shaped, and tapering to a point, making them quite thin by removing all the bark on the side that is placed towards the interior of the stock. Place the scions in position, and so that the inner bark corresponds with that of the stock; then remove the wedge, and bind securely with matting, and finish off with a good coating of clay.

Saddle Grafting is not much in vogue, although a somewhat modified form is frequently used in the West, and formed the writer's first lesson in grafting. In this method the stock may be double the size of the scion, although uniformity in size is to be preferred. The latter is cleft for about 3 or 4 inches upwards from the lower end, so that one side is thicker than the other. The rind of the stock is slit down and opened to receive the thicker side of the scion, the thinner being set astride the stock (the point of the latter should be cut off in a sloping direction) and down the other side, a small portion of the bark of the latter being removed corresponding in size to this end of the scion, which should fit closely and evenly to the stock (see figs. 65, 66). Afterwards tie up securely with matting, and cover with clay. This kind of grafting may be practised with success until quite late in the season.

Side or Bud Grafting.—This method, a modification of whip-grafting, is useful for supplying buds to espalier, horizontal, or other trained trees, especially of Apples or Pears, where otherwise the loss of a shoot destroys the symmetry of the tree; and it is sometimes employed in the case of new varieties so as to hasten fruit-bearing. A short slice is notched out of the stock at the spot desired to insert the scion, which in this case carries but one bud, and when inserted it should be exactly in the position it is wished the new shoot should start from, and the bud pointing in that direction. It should be carefully tied in with matting, and a little clay or grafting-wax smeared over the parts (see fig. 67).

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	MAR. 25	—Royal Botanic Society meet.
TUESDAY,	MAR. 28	Royal Horticultural Society's Committees.

SALES.

TUESDAY,	MAR. 28	Imported and Established Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY,	MAR. 29	Japanese Lilies, Continental Plants, Tuberoses, Carnations, &c., at Protheroe & Morris's Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period March 12 to March 18, 1899. Height above sea-level 24 feet.

"The Silva of North America."

THE twelfth volume of Professor SARGENT'S monumental *Silva of North America* has been published (Boston: HOUGHTON, MIFFLIN & Co.). It should have been the last, but, as a publisher's note tells us, a thirteenth volume will be required, to contain the general index, and to include descriptions and illustrations of recently-discovered species. The present volume is of particular interest to British cultivators, as it contains accounts and figures of so many of the coniferous trees grown in our parks and arboreta. The history of many of these has been, till recently, a tangled maze, with a correspondingly complicated synonymy and nomenclature; but gradually, as further information has dawned upon us, much of the confusion has been cleared up, and the present work, with its excellent illustrations, will greatly contribute to the completion of this result; though, unfortunately, in some cases, it will have the opposite effect, at least temporarily.

Professor SARGENT'S personal explorations and investigations of the trees in their native localities invest this work with supreme importance. We have long since exhausted our vocabulary of appreciation of the *Silva*, and with reference to this volume we can but repeat what we have previously said.

But the changes in nomenclature which the author has felt it his duty to adopt are simply distressing. They are based upon a system which is not in general use on this side of the Atlantic. A few illustrations will suffice to show how disquieting this new, and, as we think, unauthorised system is. When we come to the Black Spruce, which we had settled to call Picea nigra of Link., we find that in future we are to call it P. Mariana, and if we look to the synonymy, as here given, we find the name Mariana is adopted because MILLER, in his dictionary, called it (*not* Picea), but Abies Mariana; so that, according to the new system, we are to concede priority to the half of a specific name only, even when that half has been placed in a genus that everyone now admits to be the wrong one. The usual practice in this country is to adopt the complete name applied by the monographer who first placed the plant in its proper genus. The idea, in the American system, is to recognise the work of the first investigator, and to give priority to the earliest name. Everyone admits the claims of priority, but then it should be controlled by accuracy of determination, which is a matter of much more importance than mere priority of name; whilst the original author is recognised in the synonymy.

The Red Spruce, which has been so confused with the White Spruce, is here called Picea rubens, a new name, adopted for the purpose of cutting a Gordian knot. The White Spruce, our Picea alba, becomes Picea canadensis, for reasons which it would be tedious to discuss in these pages. The beautiful P. pungens, the blue forms of which are so handsome, is here called P. Parryana, the reason for which change is not apparent. Professor SARGENT tells us that the varieties of this Fir, which are so beautiful in the young state, lose, after a few years, their beautiful blue colour. A tree in our own garden, which has been a model of symmetry and beauty, is now becoming ragged and bare at the base, and losing its exquisite colour; so that there is some fear that this tree, which promised so well in a young state, may lose its beauty as it gets older, and if so, the question as to its name will be of less importance—at least, to cultivators.

When we come to the beautiful Tsuga, generally known as T. Mertensiana, and frequently as Albertiana, we again find an entirely new name, T. heterophylla, for reasons which, if lawful, are certainly not expedient. The Tsuga which we had come to know as T. Pattoniana is now to be called T. Mertensiana, an interchange which will cause the direst confusion. Professor SARGENT, in company with Messrs. CANBY and MUIR, found two species near Sitka, one the Tsuga Pattoniana, the other T. Mertensiana, "and it became clear that BONGARD'S description of Pinus Mertensiana could belong only to the Patton Spruce. Therefore this tree should be known as Tsuga Mertensiana, while another name must be found for BONGARD'S Pinus canadensis. That of RAFINESQUE, published in 1832, Abies heterophylla, is the next oldest name. The possibility of identifying the tree described by RAFINESQUE under this name has usually been doubted, but his description was based on the following account in the Journal of LEWIS and CLARK. . . ." (Here follows the description.)

Surely it would have been better to have made no change in the nomenclature, but to have given a sufficient explanation in the synonymy. BONGARD put the plant in the wrong genus, or in what we now think the wrong genus, therefore his name can only rank as a synonym. RAFINESQUE also placed the plant in the wrong genus, and the identity of his plant is open to doubt, or can only be identified by a passage in some one else's book!

Perhaps the most vexatious change is in the nomenclature of the Douglas Spruce. We had become accustomed to consider this as Pseudotsuga Douglasii; but the name here adopted is Pseudotsuga mucronata, of SUDWORTH, dating only from 1895. This name, "mucronata," is taken from RAFINESQUE'S Abies mucronata. Now, the tree is no Abies, according to our present notions, and RAFINESQUE'S identifications are usually open to so much doubt that they have generally been disregarded (we do not know whether there is less doubt in this case or no).

The variety macrocarpa is raised to the dignity of specific rank rather than of a geographical form.

Abies bracteata, a name dating from 1849, is superseded by A. venusta, dating from 1873, according to the synonymy here given, the change being made because DOUGLAS called it Pinus venusta, preference being given to the prior use of one correct half-name associated with one incorrect moiety.

However embarrassing and vexatious these changes of nomenclature may be to the present generation of cultivators, they do not seriously detract from the great value of the book to botanical students, because an ample synonymy and indices are given, and very often the dates are also appended.

Ample details concerning the geographical distribution, the rate of growth, and the value of the trees for economic or for ornamental purposes are given, so that the *Silva* is a veritable encyclopædia of all that is known with regard to the trees of the North American continent, exclusive of Mexico.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fruit and Floral Committees of the Royal Horticultural Society will be held on Tuesday, March 28, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Some of the Plants Exhibited," will be given at 3 o'clock by the Rev. Prof. G. HENSLOW, M.A., &c.

HORTICULTURISTS AND THE BAILIFF.—Many of our readers have at one time or another attended the meetings of the Royal Horticultural Society at Westminster. Probably many of them are also aware of the mews that run alongside the Drill Hall, and where are baited most of the horses that are necessary to draw the exhibits from the various horticultural establishments to the exhibition. On the occasion of the last meeting, events proceeded as usual so far as the exhibitors were concerned until the afternoon. But, meanwhile, certain events had taken place. It appears that the occupier of the mews had a certain creditor (to the amount of £70) who, for reasons best known to himself, had decided to place the stabling and contents under the care of a county court bailiff. Ordinary business instincts suggested that such a proceeding should take place on a "Tuesday," as we horticulturists know it. On such a day the stables are nearly full of well-conditioned animals. Words are inadequate to describe with what feelings exhibitors learned the nature of the state of things. Persuasion and threats were unavailing, the heartless bailiff, as is his wont, remained unmoved by either. Affairs were rapidly becoming desperate. The plants were likely to suffer injury from remaining in the Drill Hall all night, and the horses were in danger of being sold under the auctioneer's hammer. Happily, the Council of the Society happened to be sitting at the time, and fortunately —from the general exhibitor's point of view—the impounded horses included two animals belonging to Sir Trevor Lawrence, Bt., and his influence in the end saved the situation. The honourable baronet proceeded to the Sheriff's Court and explained the position of himself and his horticultural friends to that representative of British law, and to the intervention of this dignitary do the exhibitors owe the recovery of their living motors. In future, it would appear to be necessary to obtain a written certificate as to the financial circumstances of the owner of a stable, before one determines to entrust his steeds to such a place.

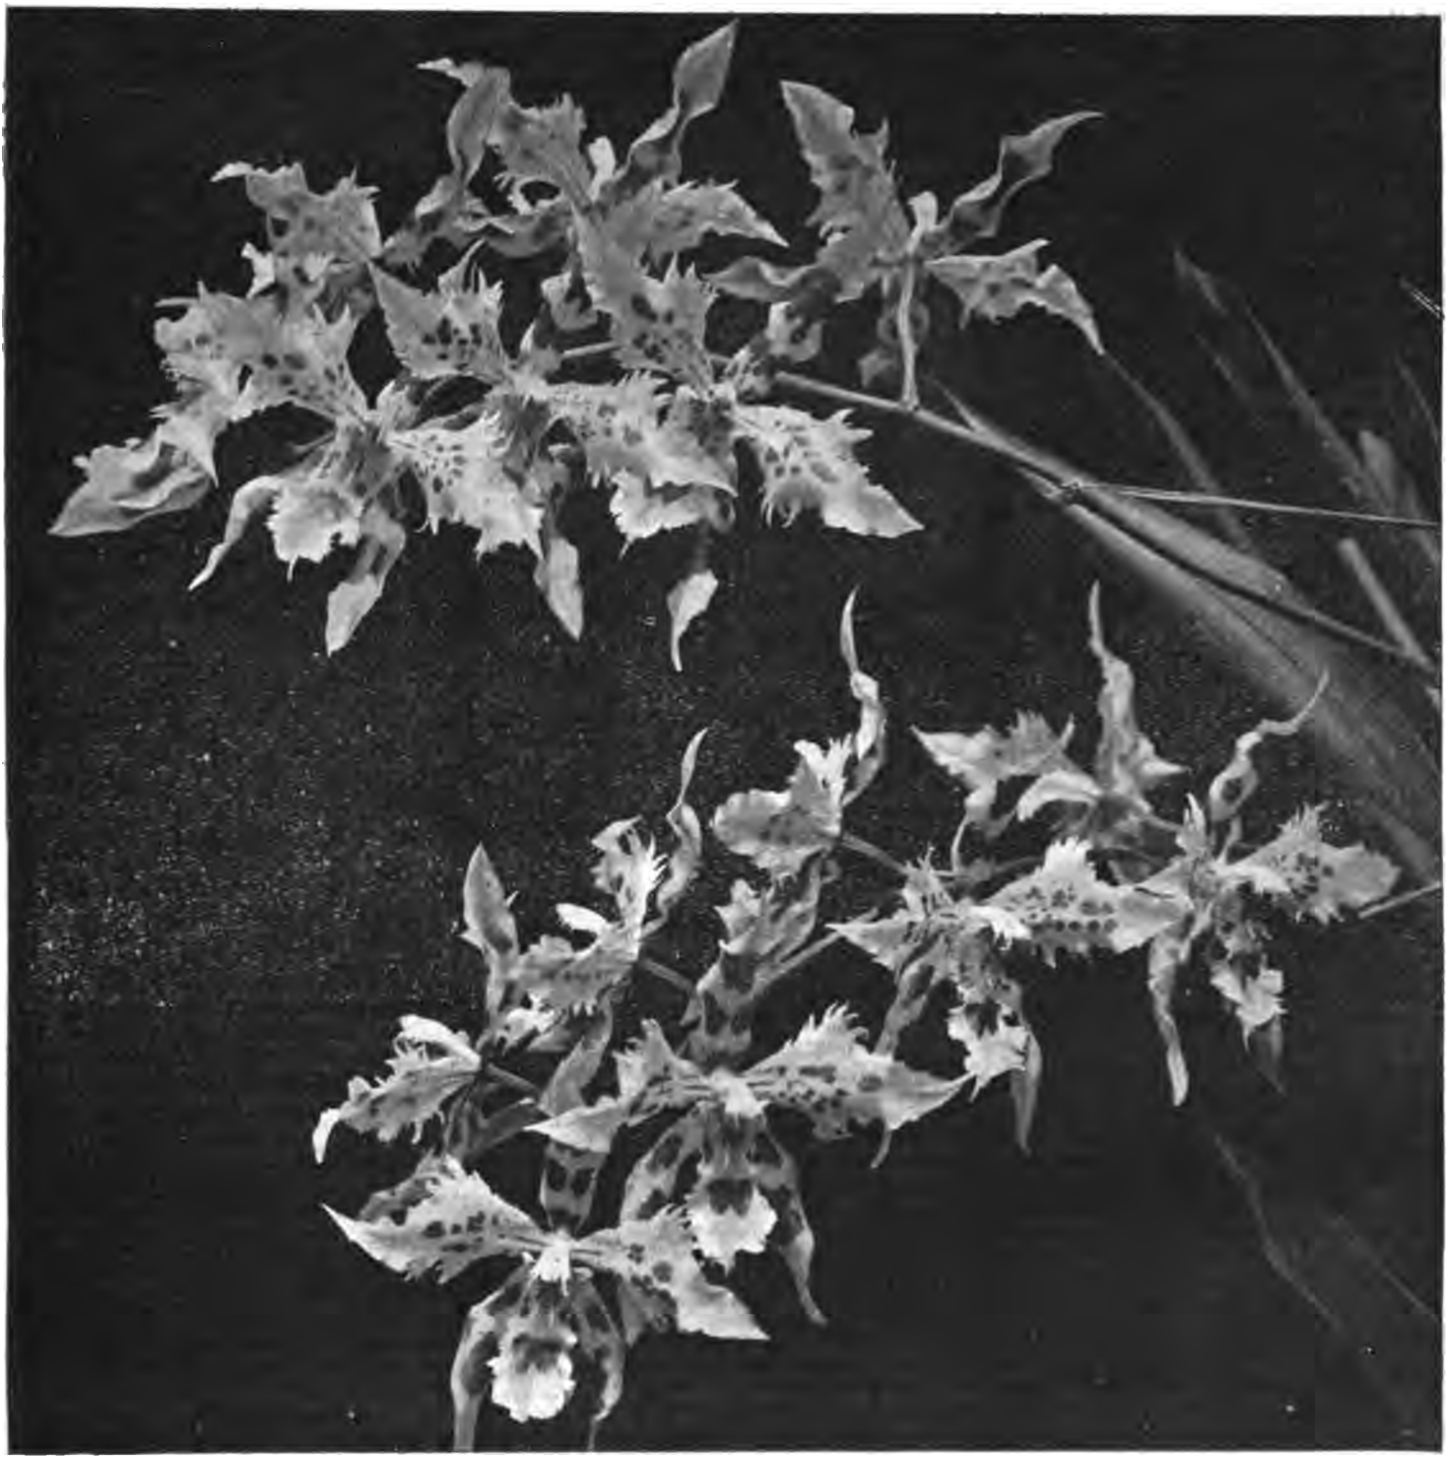

Fig. 71.—Odontoglossum Wilckeanum var. pallens, in Mr. Leemann's Garden, West Bank House, Heaton Mersey. (See p. 188.)

The Nurserymen's, Market Gardeners' and General Hailstorm Insurance Corporation. — The fourth annual meeting of the shareholders will be held at Simpson's, 101, Strand, London, on Monday, the 27th inst., at 3 p.m. The report is very satisfactory, showing an increase of 27 per cent. in the premium income. The directors recommend the payment of a dividend of 5 per cent. on the paid-up capital, a bonus of 5 per cent., and that £200 be added to the reserve fund. The directorate is very strong, consisting almost entirely of the leading members of the trade. The Secretary is Mr. A. J. Monro, 1, King Street, Covent Garden. As the advantages offered cannot be too widely known, the directors draw attention to the benefits of insuring with this Corporation, viz., that those insured can replace immediately their own glass broken by hail, the corporation paying them at the rate per square foot at which the glass is insured. Another advantage, and of which several insurers are availing themselves, is that of being able to cover wholly or partially the value of the contents of their glasshouses by increased insurance of their glass—an advantage offered by no other insurance company.

National Carnation and Picotee Society.—This Society, which has as its president Martin R. Smith, Esq., appears, from its twenty-second Annual Report, to have experienced a most successful year, as with the end of its financial year it had a balance in its favour after meeting all expenses of no less a sum than £253 15*s.* 7¼*d.* The total receipts amounted to £526 9*s.* 9½*d.*, Mr. M. R. Smith's special prizes amounting to the sum of £19 7*s.* The prize-money disbursements amounted to £182 16*s.* 6*d.* In regard to the various sections of Carnations, much improvement has been noted in recent years in selfs and fancies, and more especially in yellow-coloured selfs, fancies, and Picotees. Flakes, bizarres, and whites are said to be stationary, although improvement may be confidently looked for. The Society distinctly claims to have been instrumental in bringing about this satisfactory state of things. The schedule for the present year has been revised to a considerable extent, and some new classes have been added. Moreover, the dressed blooms are divided into three sections, so as to suit the different classes of cultivators—a very necessary alteration, as by this arrangement the competitors are placed on a more equal footing. This scheme was devised by the President, who also gives a Silver Cup to each section to be awarded to the exhibitor gaining the greatest number of points in that section. Attention is called in the report to the new "triplicate blooms" in the third division, and to the exhibits without dressing or cards, which, it is hoped, may prove attractive to exhibitors. A list of the winning varieties being now published in the annual report, it is not considered to be necessary to hold an election of varieties as has hitherto been done.

Southern Counties Carnation Society.—This Society presents its first annual report, and we are enabled to gather from the gratulatory opening paragraph, that success has waited on its venture as a rival of the National Carnation Society in its bid for support among the cultivators and admirers of Carnations. The members number at the present time 200. The first exhibition, held in July last, was a success, although the season was adverse and the day rainy. The committee feel that the thanks of the members are due to Mr. William Garton, jun., for his exertions to make the Society a success. Mr. A. Johnston, 26, St. Mary's Road, Southampton, is the assistant secretary, to whom all communications should be addressed.

The "Journal of Horticulture" for March 9 is worthy of preservation as containing a sympathetic account of many of the principal writers in that much-esteemed periodical, together with portraits of some of the principal contributors from the time of its establishment till the present time. Thus, we find portraits of Robert Errington, Donald Beaton, Pearson of Chilwell, Thomas Rivers, and George Abbey, not to speak of others happily still with us.

Dante, and the Action of Light upon Plants.—In a recent number of *Nature* is a very interesting article on this subject by Professor Italo Giglioli. The Professor gives several illustrations proving that the great Italian poet had sound ideas as to the action of solar heat and light upon plants, and that his views and those of his contemporary, Pier de Crescenzi, were far in advance of the time. It was not till the time of Ingen Houss and De Saussure (1774-1804), indeed, that the truth was demonstrated. The following passage from Dante may be set by the side of those which recall the fact that in the consumption of coal we are but liberating the sun-heat and light stored up in primæval forests, and that Cucumbers and other fruits are so much "bottled sunshine."

> "Behold the sun's heat which becometh wine,
> Joined to the juice that from the Vine distils."

These verses are stated to have been suggested by a passage in *Cicero de Senectute.* In their turn they influenced Leonardo da Vinci in the belief that "the sun giveth spirit and life to plants, and the soil with its moisture nourisheth them." Galileo believed that wine is a compound of light and sap; and Dante asserted that both oil and wine are formed by the action of solar heat and light on plants. Pier de Crescenzi (1305), a contemporary of Dante, laid special stress on the action of heat and light on plants, and alluded to the hardening influence of light upon vegetable tissues (ripening of the wood in gardeners' phraseology). "Plants in warm weather," says Crescenzi, "grow in the darkness of night, and in the heat of the sun they harden and become woody." "The splendour of the ancient literature," says Prof. Giglioli, in conclusion, "dawning again upon Italy, overpowered the rising of the new science. The generations that followed Dante became more erudite than learned; and the new knowledge slept again through the centuries, just showing life with Leonardo da Vinci and a few others, until the unlocking of the gates of sense and the kindling of a greater natural light in the days of Bacon and Galileo."

Floral Decorations (?).—A pillow for the funeral of a wholesale butcher at Toronto was "adorned" by a floral device representing a blue bull in the centre, with head down and tail erect. We take this "elegant extract" from the *Florists' Exchange.*

The Topographical Botany of the West of Scotland.—A work on this subject, by Mr. Peter Ewing, F.L.S., is announced as ready for publication. The country embraced extends from Ayrshire to the Hebrides, and includes fourteen of the Watsonian vice counties, details of which are given in the introduction, so that they can be easily traced on any map of Scotland. Remarks are made on doubtful natives, nomenclature, Rubus, Rosa, Hieracia, and Salix. An index is given to all the genera recorded, also a list of author's surnames in full, commonly attached to the name of a plant in an abbreviated form. The work extends to about 200 pages, demy 8vo, is bound in cloth, and is published at 2*s.*

"Willing's Press Guide."—This is a list of the newspapers published in the United Kingdom and elsewhere. The list is, in the first instance, alphabetical, and in the succeeding pages, classified according to subjects. No fewer than twenty-one publications relating to gardening are specified. Another section contains lists of the newspapers and other periodicals published in the various counties of Great Britain and Ireland. A list of the principal newspapers published in the colonies, in the United States, and on the Continent of Europe is given, so that the book is of the nature of an encyclopædia.

Horticultural Club.—The usual monthly dinner and conversazione took place on Tuesday, 14th inst., at the rooms of the Club, Hotel Windsor. The chair was occupied by Mr. R. Gofton Salmond. The subject for discussion was the planting and pruning of single Roses, and was opened by Mr. George Paul, V.M.H., who said that a different system must be adopted in their planting to that which was pursued in the case of Hybrid Perpetuals, Teas, and Hybrid Teas. There were three ways in which, he said, they might be advantageously used: trained horizontally so as to form a fence or hedge, and for this purpose he advocated hurdles (on which the Roses might be trained), and supported by five barred iron fences; they might be most advantageously used as single specimens on lawns, supported by a Larch pole; or as single plants in shrubberies amongst other flowering shrubs. With regard to planting, it must be remembered that as they are to remain permanently, they should have more space afforded them than the ordinary dwarf H.P.'s or Teas, and liberal provision should be made for their future welfare. A hole, about three feet in diameter, should be made and filled with good Rose-compost. With regard to pruning, it was necessary to bear in mind that they should be treated very differently to the H.P.'s and Teas, only requiring the three-year-old wood to be cut away, the two-year-old wood to be laid in, and the one-year-old shoots very slightly shortened. A very interesting discussion followed the paper, in which all present joined, and a cordial vote of thanks was awarded to Mr. Paul for his interesting paper.

Old World Gardens.—An exceedingly bright and interesting collection of water-colour drawings, by Mr. E. Arthur Rowe, is at the present time on view at The Dowdeswell Galleries, 160, Bond St., W. Old-world gardens, in a good state of preservation, are not numerous in this country, and they are constantly being sketched by artists. Many of those now very exquisitely reproduced by Mr. Rowe have been seen before from the brush of such practised artists as Mr. Parsons, Mr. Elgood, and Mr. Fulleylove. We refer in this instance to pictures of such places as Penshurst Castle, Montacute House, Levens Hall, Bulwick, Arley, Loseley Hall, Berkeley Castle, Haddon Hall; the topiary work, and the Yew-walk, Elvaston; views at the Villa Palmieri, Villa Borghese, and others—old friends all, but none the less worthy of seeing through another artist's eyes.

Apples from the Antipodes.—We have been informed by the officials of the Orient Company that the *Oruba*, from Hobart, due April 15, will bring 7,000 cases of Apples; and the *Oceana*, due on the 22nd proximo, will bring 10,500 cases.

A Spring Flower Show at Ealing.—This is now an annual occurrence, and is arranged by the members of the Ealing and District Gardeners' Society in aid of the gardening charities. The above exhibition took place in the spacious Victoria Hall on the 21st. inst., the proceeds to be divided between the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund.

The Severity of the Weather during the past week is evident from letters we have received from numerous correspondents. On the night of the 20th inst., we are informed, that at Broxbourne (Herts), there were 20° of frost, at Catford 18°, at Gillingham, in Norfolk, as much as 27° of frost, and at Woburn 34° of frost, or 2 below zero!

Cape Fruit.—The Union Company's steamer, the *Moor*, from the Cape, brought 189 boxes of Grapes, 36 of Plums, 7 of Tomatos, and 8 of Bananas. The Grapes, mostly white, were in good condition, and have realised good prices; a few boxes were Black Hermitage—small and poor; the Plums were again of excellent quality, though not quite such large fruits as those already received. The Bananas were from Natal, and shipped on deck. These arrived in quite a rotten condition, which seems to show that the fruit will not carry well in some cases. The Tomatos were a private consignment.

Kew Men.—The value of the training given to gardeners employed at Kew is shown by the number that obtain good situations from that establishment. We learn that since January, 1898, eighteen first-class appointments have been made from Kew, including seven curators and assistants of botanical gardens in the colonies and

India, two collectors in Africa and China, five head gardeners, and four nursery foremen. Applicants for employment at Kew must be over twenty, and under twenty-five years of age, and they must have had a good training before entering Kew for the two years' course given. It will be seen that these appointments are filled by comparatively young men. Applications should in the first instance be made to the Curator, Royal Gardens, Kew.

A Market Gardener and a Welsh Coal Strike.—An interesting case was settled on the 16th inst. in Mr. Justice Grantham's Court, when Mr. Green, of Riverside Vineries, Hampton, sued Messrs. Cann & Co. of Swansea, for damages arising out of failure of contract. Mr. Green had contracted with Messrs. Cann & Co. in November, 1897, to supply him with sixty tons of anthracite coal at such times and in such quantities as he should require. The colliers strike, however, prevented the defendants from keeping the contract. Mr. Green had six large greenhouses containing 11,000 Tomato plants, and some Beans for forcing. He could not obtain the coal contracted for, and estimated the value of crops thus lost at £435 for Tomatos, and £422 for Beans. Council for defendants contended that plaintiff was not entitled to claim for loss of crops, but the difference only between the contract price with defendants and the price at which he could have obtained the necessary fuel elsewhere. The court accepted this view, and after expert evidence had been given that plaintiff could have obtained the 35 tons of coal which defendants failed to supply at a loss of £8 2*s*. 6*d*., this sum was awarded to plaintiff.

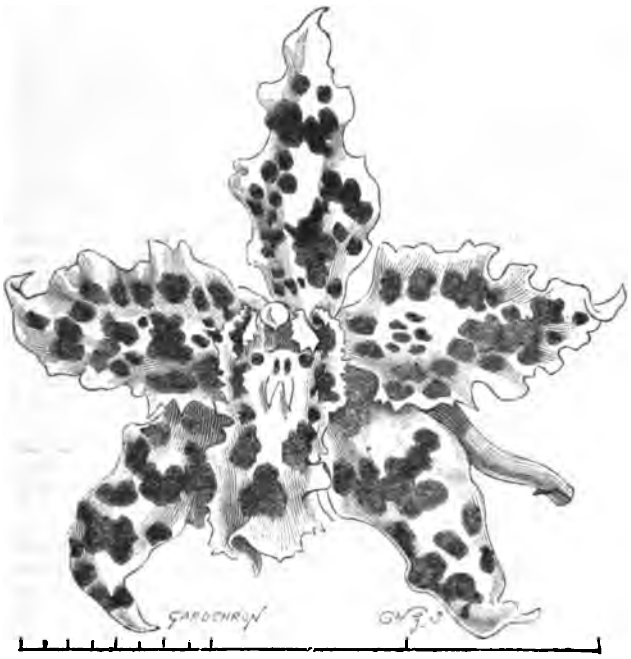

Fig. 72.—Odontoglossum crispum "Mrs. John Leemann."

For description of which, see "Orchid Committee," in Report of Royal Horticultural Society, in *Gardeners' Chronicle* for March 18, p. 174.

Hardy Fruit Culture.—At the meeting of the Chiswick Gardeners' Mutual Improvement Association on Thursday, March 16, a paper was read by Mr. R. Lewis Castle, Manager of the Woburn Experimental Fruit Farm, on "Hardy Fruit Culture, its Problems, Profits and Prospects." The problems were classed under the heads of Tree formation and Fruit production, special reference being made to stocks, budding and grafting, pruning, planting, manures and cultivation, as affecting growth or fertility, while, as regards the latter, particular attention was called to the influence of foreign pollen, and the advantages of interpollination in counteracting sterility. The average gross returns per acre from fruit culture were noted, and the average expenses, together with the essentials to success. In regard to the prospects, it was contended that if the United Kingdom is favoured with peaceful times, there is a great future before the cultivator of hardy fruits, because the value of these products, as an important part of a healthful diet, is rapidly becoming more generally recognised. The discussion was opened by Mr. S. T. Wright, Superintendent of the Chiswick Gardens, who detailed many experiences in support of the principal points. He was followed by Mr. E. Camp, Mr. A. Bridges, Mr. J. Fraser, and several other members, in an animated, interesting, and prolonged discussion, at the conclusion of which Mr. Castle briefly replied on the various points, and the proceedings closed with a unanimous vote of thanks to Mr. Castle, proposed by Mr. S. T. Wright, and seconded by Mr. A. Bridges.

The Natural History of Plants.—The admirable work by Herrn Kerner von Marilaun and Prof. Oliver is now being issued in parts, with the original illustrations and letter-press, by the Gresham Publishing Co. It can only be obtained from them or their agents by subscribers.

Potato-grafting.—M. Bornet, in a recent number of the *Journal de la Société Nationale d'Horticulture de France* (p. 193), alludes to an observation of M. Strasburger that atropine has been detected in the tubers of Potatos on which Datura Stramonium has been grafted (Berichte d. Deutschen Botanischen Gesellschaft, p. xxxvi.). This is a very remarkable illustration of the effect of the scion on the stock; but it is not an experiment that it is desirable to repeat outside the laboratory, or, at least, the experimental plot.

"The Smithsonian Report."—The Annual Report of the Board of Regents of the Smithsonian Institution to July, 1896, has reached us, and the contents are, as usual, of great interest. The volume includes a general appendix devoted to papers on Astronomy, Mathematics and Mechanics, Physical Geography, Recent Advances in Science and their Bearing on Medicine and Surgery, Processes of Life Revealed by the Microscope, Biologic Relations between Plants and Ants, &c. There are numerous plates, some appealing chiefly to the scientist; others, those, for instance, representing samples of ancient "pueblo" work from Arizona, of more popular interest. They are indeed beautiful reproductions of wonderful specimens of primitive handicraft. The paper on the Biological Relations between Plants and Ants is a clear account of a subject engaging the attention of both botanists and entomologists. The author (Dr. Heim) is fully up to date in his facts and observation, while the general tenor of his opinions may be gathered from his own words, that:—"Disregarding the sufferings and death of individuals, evolution tends to establish between beings primitively rivals a *modus vivendi* that assures the free expansion of the species; a progressive expansion that must soon find its limits in the new struggle that species, triumphing by their union, must make against neighbouring species."

Continental Novelties. — The list of novelties issued from the National Arboretum and Alpine Garden of Zöschen, near Merseburg, is so large, that we cannot enumerate them individually. They comprise deciduous trees and shrubs, Magnolias, Ilexes, &c. The catalogue of alpine plants issued from the same establishment is also very rich.

Cold in Florida.—We are so much in the habit of bemoaning the variations of our own climate, and its many drawbacks, that it may be of advantage to us to see that climatal variations are met with even in the Gulf of Mexico. The following extract from the *American Florist* may be of interest as confirmatory of the remarks of a correspondent at p. 158.

> "On the nights of February 12 and 13, and also during the days, we experienced such weather as we have never had before. The temperature went down to 6° above zero; the lowest we have ever had in later years was 15° above. The condition of our gardens is hard to describe. Not only private gardens are ruined, but there is a heavy loss among the florists. Some of them count their loss by the thousands of dollars, and a good many of them are satisfied to have lost only a few hundreds. You know that the majority of our tender plants are raised in hot beds. They were no protection at all against 6° of cold. Our greenhouses were not heated enough nor closed enough. It will teach us a lesson for the future. Even our Roses, chiefly Teas, are all dead. Fig-trees, different Magnolias, and sweet Olives, as old as New Orleans, are peeling off their bark. Phœnix canariensis, which had stood every winter before, will be killed, or, at least, badly damaged. Chamærops seem to have stood the most. Many orders will have to be sent north to replace our loss." *The American Florist.*

General Horticultural Exhibition at Lyons.—The Société d'Horticulture du Rhône is organising a general Horticultural, Artistic and Industrial Exhibition, to be held at Lyons from the 3rd to the 12th of November, 1899. This exhibition will be coincident with the fourth Congress of the Société Française des Chrysanthemistes, and a grand International Chrysanthemum Congress will be held at the same time. Numerous prizes, medals, and other awards are offered in connection with the various sections, the programme for which can now be obtained from M. G. Chabanne, Secrétaire-general, Palais des Arts, Lyon (Rhône). Special railway facilities are offered to intending exhibitors.

WEST BANK HOUSE, HEATON MERSEY.

Within a short distance of Stockport, the great centre of the cotton industry, the beautiful gardens of J. Leemann, Esq., some 15 acres in extent, and containing one of the most select and well-grown collections of Orchids in the country, afford a remarkable instance of what a successful man of business with a love of horticulture can accomplish in a very short time. The beautiful gardens, and the dwelling-house, with its conservatories, have been brought to their present perfect state in less than four years. The owner of late has made the more showy Orchids his chief recreation, but not the only one, he having an earlier hobby in the collection of tropical butterflies and moths, both being due to extensive travels in out-of-the-way parts of the world.

The Orchids.

These plants are elevated to the chief place in the gardens, and evidence of them was immediately found in the cut flowers of Cattleya Trianæi and other species arranged in the dwelling-house. In the conservatory adjoining the billiard-room was a fine bank of Orchids in flower, which we were informed is maintained the year round without any noticeable injury to the plants; firstly, because the electric light is used; secondly, by reason of the plants being afforded water with care and kept dry rather than wet; and thirdly, the flowers are cut from the plants when a reasonable time has elapsed.

This fine bank consisted recently of the finest selected varieties of Cattleya Trianæi, showy Dendrobiums and Odontoglossums. Of the former the colours range from pure white, to white with ruby lip; and through all shades of colour to rich rose-crimson, the form of the flowers in all cases being perfect. The handsome West Bank House variety, is remarkable, not only as regards its flowers, but from its growth, which suggests Cattleya Warscewiczii. In the study close at hand were portfolios of coloured drawings of most of the finer Orchids, the arrangement of the drawings rendering comparison easy. Of the Dendrobiums, the unequalled D. nobile nobilius, of which there were many specimens, stand out prominently. Then come D. n. Ballianum, a contrast, the blossoms being nearly white. D. n. Cooksoni, with its quaintly-coloured petals; D. n. Cypheri, white, with maroon centre, and rose-coloured tips; D. n. Sanderianum, one of the most beautiful in colour and shape; and others equally good, which have come with various importations. Of other Dendrobiums, the handsome forms of the class of D. × splendidissimum grandiflorum, which, like the stronger forms of D. nobile, Mr. Edge, the gardener at West Bank House, succeeds in getting flowering growths of upwards of 4 feet in height, and proportionately stout; D. nobile albiflorum, D. × Ainsworthi, Cypher's variety; D. Wardianum, and D. W. album, and others appear to advantage. At the back of the bank were fine specimens of Cymbidiums just expanding their flowers, the front being made up with Cypripediums, which, although not liked so well by Mr. Leemann as Cattleyas, Lælias, and hybrids of these genera, are still of use in decorative arrangements. There were remarked also C. villosum giganteum, the finest form of the species; C. × Creon, C. × nitens superbum, and the best forms of C. × Calypso, C. × Lathamianum, &c.

The Winter Garden.

This structure is on a lower level, and here were seen some good Cymbidiums, intermixed with fine foliage plants. The other plants in this garden consisted of specimen Camellias, which were beginning to blossom. Presently the commodious block of Orchid-houses, constructed under Mr. Leemann's direction by Messrs. R. Halliday & Co., of Middleton, was reached, in which was found a sturdy collection of Cattleyas, Lælias, and Lælio-Cattleyas. The last-named race of crosses, of which a grand collection was remarked, take the lead. Flowering for the first time, as we were told, was a grand novelty in Cattleya × Octave Doin, having a flower with a certain resemblance to C. × Hardyana, but with evidence of C. Mendeli in the elongated, crimped, ruby-crimson coloured lip. Other remarkable plants were Lælio-Cattleya × Amy Leemann and L.-C. × Marguerite Maron. In both cases L.-C. × Schilleriana is probably the parent, and not L.-C. × elegans, and the parentage would seem to indicate forms of L.-C. × Henry Greenwood—but a comparison has shown them to be distinct, as they are florally more showy, especially in the development of the front part of the lip; a fine plant of a hybrid between Cattleya Warscewiczii and L.-C. × Dominiana, said to bear flowers 11 inches across; another between Lælia tenebrosa and L. Digbyana, and various other singular crosses, most of which will soon bear flowers. Of other showy hybrids there are numbers of Lælio-Cattleya × Canhamiana, L.-C. × callistoglossa, L.-C. × Aphrodite, and many other showy hybrids which never fail to afford variety. There were noted vigorous plants of Lælio-Cattleya × Berthe Fournier, L.-C. × Arnoldiana, L.-C. × Sallieri, L.-C. × eximia, L.-C. × Gottoiana, and most of the other showy Lælio-Cattleyas.

Favourite things, and especially those certain to produce fine varieties or natural hybrids, have been purchased unflowered in quantity, preference being given to Cattleya aurea. The venture has already been productive of many splendid C. × Hardyana, and out of the hundreds still unflowered, some remarkable forms will probably result. More than one were credited as "white gigas," and these are being watched with great expectation.

The Odontoglossum Houses.

These form another notable feature, sharing with the Dendrobiums the second place after the Lælio-Cattleyas and Cattleyas. The strain of O. crispum is a very fine one, some of the flowers at present showing being circular, and of large size. One group of them has been remarkably prolific of crosses, some splendid O. Andersonianum, O. Ruckerianum, O. Wilckeanum, &c., having flowered out of it. One of the more beautiful is O. Wilckeanum var. pallens (fig. 71), which has nearly white flowers, spotted with red-brown, and which, although in colour approaching O. crispum, it forms a well-defined example of O. × Wilckeanum, although departing from the ordinary type of that species. Many other strange-looking hybrids, or probably spotted forms of O. crispum were in bud, and full of promise. Many fine O. triumphans and others were also in bloom.

The Dendrobium-house

was a scene of luxuriant growth and good flowers, and among other remarkable subjects were two of Cattleya labiata Peetersana superba, which were carrying flowers of an intense purplish-crimson, similar in colour to those on the plant which recently realised such a large sum of money, but they were larger, and of better shape. C. Trianæi Constance Leemann, and C. T. Empress, are two very distinct and charming varieties; Lælia anceps Leemanni, the largest and finest-coloured L. anceps; two superb, round-flowered Vanda cœrulea; some fine Lycaste Skinneri alba; Odontoglossum Ruckerianum illustre, a very showy form, were remarked. In every class only those which are superior are retained.

The Gardens.

The land forms an undulating slope towards the south, and the chief noticeable features are the immense beds and borders of fine Rhododendron hybridum, which in their season must form a gorgeous display. The garden is protected by plantations of Hollies and Conifers, whose front borders are filled with bulbous and herbaceous perennial plants. Here and there we noted beds planted with Carnations and Auriculas; and beyond is a large fish-pond, fed by a natural spring. To the left is a miniature farmyard, and beyond this come the fine new ranges of fruit-houses and the kitchen-garden, and at the further extremity of the last is the gardener's house. The whole is brought into communication by telephone; time and labour-saving appliances appear on all hands, and but little could be suggested to improve Mr. Leemann's plan, which embraces the making of a new garden to look like an old one, and to further which idea fine old standard Hollies, Irish Yews, &c., are introduced, and climbing Roses and other rustic trailers profusely arranged in salient spots.

HOME CORRESPONDENCE.

ROYAL GARDENERS' ORPHAN FUND.—"A. D." made some pertinent remarks on the above Fund in the *Journal of Horticulture* on February 23. He deplores the fact that not one of the fathers of the nineteen children nominated for election this year had been a subscriber to the Fund, and also to the indifference of gardeners generally in not becoming subscribers, and asks, "Can anyone explain it?" I am afraid it is difficult of explanation. A glance at the list of subscribers for 1897 reveals the fact that many men occupying prominent positions as head gardeners do not subscribe to the Fund, and whom we may assume could well afford the sum of 5s. or more per annum. It is possible the claims of the Fund have not been brought home to them by personal solicitation; but the large majority of gardeners are poorly paid, and can ill afford even the small sum of 5s. per year [This cannot be true of gardeners as a class. Ed.], and especially as they have no guarantee that their children will receive the benefits of the Fund should they require it. As a worker for eight years on behalf of the Fund, I have solicited scores of gardeners to become annual subscribers, and what is the result? I have four gardeners on my book, the remainder being nurserymen and private ladies and gentlemen. Some whom I have asked say, "We have no guarantee that we shall receive any benefit; we have no voice in the management, as we live at too great a distance from the place of meeting. It is those living near who can do as they like, and pull the strings on behalf of any candidates for election." I do not endorse these views, but have every confidence in the executive committee; and I should like to impress on the great body of gardeners the necessity of becoming annual subscribers, and if there is anything in connection with the Fund they do not approve of, let them make it known through the horticultural press or otherwise. I know from experience the editors are pleased to give the humblest individuals every opportunity to express their grievances. The time will come when it will be the children of subscribers who will benefit by the Fund; but it must not be two children from one family to the exclusion of children from other families whose claims are equal or more deserving. At the last annual meeting the following was added to Rule XI.—"Not more than two children of the same family can be in receipt of the benefits of the Fund at the same time." Previously, the rule did not specify how many children from one family might receive the benefit of the Fund. But why should two of one family receive the benefit of the Fund, while other families are left out? Surely the Fund is meant to benefit a number of families, and not the few. At the present time eight families have each two children on the Fund, each child being allowed 5s. per week. Mr. A. Dean suggested that at a future time it would be expedient to insist that there must be four children under 12 years of age in a family before two of its members could be on the Fund at the same time. I do not agree with him there. I suggest that only one child from a family shall receive the benefit of the Fund, unless under exceptional circumstances, such as the loss of both parents. Also, I would further suggest, that should the circumstances of the case require it, the child of a deceased subscriber who has subscribed for five or more years, shall be entitled to the benefit of the Fund without election. Or, the child might be allowed twenty or more votes for each year the father had subscribed. I know these suggestions require consideration, but it is in the interest of the Fund I make them, and I expect to hear the opinions of others; and possibly the Executive Committee may be induced to consider them, and so make the Fund of still greater benefit, and, perhaps, by so doing the great body of gardeners will be encouraged to become subscribers. *J. B. Stevenson, Hon. Local Secretary, Bournemouth.*

FRUIT PROTECTORS.—I expect to learn that your readers regard the celluloid Pear-protectors shown recently to the Fruit Committee, and figured in the *Gardeners' Chronicle* last week as toys. The Committee recommended that some of them should be tried on Pears at Chiswick this year against the old method of enclosing the fruit in muslin bags. Pears suffer most from the birds in pecking small holes near the stems. Fish netting, which by enclosing the entire tree keeps off these pests, should be by far the cheapest and simplest of protectors. *A. D.*

WINTER ACONITES FLOWERING BADLY.—I have never known so few flowers as there have been this year on the Winter Aconites in proportion to the leaves, which are abundant and vigorous. I might attribute this to the dense growth of the seedlings, but Aconites do not seem to wear out the soil where growing thick, or to mind its exhaustion by tree roots. I recollect more than half a century ago how thickly they flowered under the Lime-trees at the back of St. John's College, Cambridge, and I dare say they do so still. Lack of flowers has not been general amongst early spring plants, as Crocuses, Anemone blanda, Cyclamen Coum, Leucoium vernum, never flowered better. With regard to Leucoium, I see it stated that a robust variety, which generally bears two flowers on a scape, and is called carpaticum, has yellow tips to the flowers. My experience is, that the robust forms have generally green tips; many of these bear three flowers on a scape here; and I lately gathered one, not a fasciation, but a well-formed scape, with five flowers. *C. Wolley Dod, Edge Hall.*

LYCHNIS VISCARIA SPLENDENS PLENA.—The above variety of Lychnis, though a descendant of the British species, L. Viscaria, must not be supposed to be the old red or flore-pleno of gardens, but it is, as the name implies, an improved form, producing large panicles of brilliant rose-coloured flowers. Growers who require hardy, enduring herbaceous plants, will do well to make a note of it. *William Earley.*

THALICTRUM AQUILEGIFOLIUM ATROPURPUREUM, a very showy dark-flowered form of the Austrian Meadow Rue, was again noticeable at one of the late Royal Botanic Society's exhibitions. Growers, pending the distribution of such a fine form, should meantime grow Thalictrum aquilegifolium purpureum, as being a good contrast with Thalictrum angustifolium with pale yellow flowers, and T. aquilegium (white and bluish-pink varieties). T. minus (syn. adiantifolium) requires to be well-grown to make it really effective. *William Earley.*

SOLANUM MACROCARPUM.—Solanum macrocarpum, like S. capsicastrum and others, is valuable by reason of its fruits, which are smooth-skinned and red in colour, suggestive of small Tomatos. The plant is of dwarf, compact habit, and is very valuable for the decoration of the greenhouse during winter. The fruits are persistent for some months, even after the leaves have fallen. Its propagation may be easily effected by means of seeds, which germinate readily in any light compost. When the seedlings are of sufficient size to handle, they should be potted off and grown on without a check. In June the plants should be transferred into the fruiting-pots, which may be from 7 to 8 inches in diameter. The plants require a fairly rich compost, consisting of loam, leaf-mould, and well-decomposed manure in equal parts, and a little sand. When they have become well established they may be stood out in the open, removing them again to the house directly the fruits change colour, which under ordinary circumstances will take place during September. I have seen excellent examples of this plant grown at Kew. *P. Bolt, Wentworth Gardens.*

THE SHAMROCK.—An evening journal, *apropos* of St. Patrick's Day, raises the question of the identity of the true Shamrock. "The Shamrock," says a writer in the *Church Gazette*, "was held sacred by several nations in antiquity, and endowed by them with mysterious and magical virtues. It was used as a means of detecting evil spirits. To find a four-leaved Clover is an indication of happiness. When put under the pillow, it ensures dreams of your lover. When placed surreptitiously into the pocket of your friend it will secure his constancy. A two-leaved Trefoil, plucked at the time of the Ave Maria, is a sign that you will soon be married, and live happily ever after." This shows that the Shamrock was something more than a national emblem; and so far as the testimony is valuable, makes the Trefoil to be the Irish Shamrock. Commenting on this, the evening paper (*Echo*) has an enquiry from a correspondent —"Which plant is the real Shamrock?" and it states that "the question has more than once been put to a scientific test in Ireland, by collecting numbers of specimens worn by the people, and classifying them. They are always, or almost always, a species of Clover. Most often, the small yellow-flowered Clover, the smallest species, we believe indigenous to these Islands—that is, the Shamrock of Ireland to-day. But there is little doubt that the plant originally blessed by St. Patrick was the Wood-sorrel, a much more striking and handsome plant than the obscure little Clover now used by Irish people everywhere, which will be worn so widely to-day. The Wood-sorrel also conforms to the early tradition that the 'Shamroque of Ireland was pungent, and good to eat.' The latter (Oxalis Acetosella) is indigenous to Ireland, and it has trifoliate foliages. Spencer in his view of the *State of Ireland*, tells us that the Irish, 'if they found a plot of Watercresses or Shamrocks there, they flocked as to a feast for a time;'" Shamrocks in this case being undoubtedly the Wood-sorrel. *D., March* 17.

"EARLIEST OF ALL" WALLFLOWER. — This variety, sent out by Messrs. Sutton & Sons, has proved useful at Belvoir during the past winter. The seeds of these winter flowers were sown early in June last, and the seedlings in due time transplanted, and early in October the plants were covered with flowers, and they were then removed to the flower-garden, where flowers have been produced ever since; thus, in a mild winter like that of 1898-99, lengthening the Wallflower season by about six months. All who cherish and admire these sweet-scented old-world flowers should make a point of growing "Earliest of All," under which name it was kindly sent to me for trial three years ago. Doubtless it will soon receive other names, like many other good things. The older varieties of Wallflowers, seeds of which were sown at the same time, and the plants treated similarly, are just displaying the colour of their flowers, and the same may be said of the old double yellow, plants of which are, however, always raised from slips, and have to be accommodated with a warmer position out of doors than the others. *W. H. Divers, Belvoir Castle Gardens.*

ACACIA DEALBATA.—A specimen of this plant, the "Mimosa," of the London florists and the Riviera cultivators, can now be seen in flower on a south wall at Belvoir. It was transferred from a flower-pot early in 1894, and in the following winter, when the thermometer on the grass fell to 8° below zero, = 40° of cold, the plant was killed to the ground; but next year it threw up a shoot which has grown until, at the present time, it is 12 feet in height. Another plant put out on the grass in the Duchess's garden is also showing several bunches of flowers; but this is later than the plant against the south wall. This plant had to be transplanted last year, and its growth suffered in consequence; but it now measures 14 feet in height and 8 feet in width. Doubtless the recent mild winters have favoured these plants, for the only protection they have received has consisted of a heap of coal-ashes placed over the roots during three winter months. Is there any record of this plant flowering outside before in this country? [Yes, in Mr. Ewbank's garden at Ryde, I.W. Ed.] *W. H. Divers, Belvoir Castle Gardens, Grantham.*

RICHARDIAS.—Some time since, the summer treatment of these plants was discussed in these pages, especially in regard to planting out. The champions of the two methods having had their say, the matter was dropped. Calling at Stoke Park, Slough, the other day, I noticed one of the best lot of these plants that I have ever observed, the plants of unusual strength, and profusely furnished with spathes, several of these coming from one sheath. The plants had been grown out-of-doors during the summer; and the secret of success appeared to be in re-potting being carried out before the plants had made much growth, that is, just as the first leaves begin to unfold. Mr. Kemp pots the plants in the smallest pots the roots will go into, and then he has them placed in a shady position until they are somewhat re-established, and afterwards in a light airy house. They receive liberal applications of liquid manure, with the result that an abundance of spathes are produced of unusual size and substance. *C. H.*

IVY LEAVES EATEN.—Some leaves of Ivy have been sent me from Manchester, showing marks of having been bitten by some kind of insect. The plant grows on the walls of a house, and the sender of the leaves states that he has many times diligently sought for the marauders but failed to find them. Now Ivy is looked upon as being distasteful to insects. It has been suggested that snails are the culprits, and it may be that they are. Has anyone had similar experience of Ivy leaves being so eaten, and can they name the cause? *R. D.*

THE WEATHER IN LEICESTERSHIRE.—This morning, March 21, the thermometer in the Stevenson screen registered 17° of cold, and one fully exposed 15°; while the one on the grass indicated 20°, which is very severe for this time of the year. Many of the expanded flowers of the Peach and Apricot are destroyed, although they were protected by doubled fish netting; and Peas, sown in November and nine inches in height, are much injured. *W. H. Divers, Belvoir Castle Gdns.*

—— IN CHESHIRE.—It is twenty-six months since I have registered so low a minimum temperature as occurred here on the 22nd inst., viz., 11° on a double-column thermometer, hung exposed 4 feet from the ground. On Jan. 24, 1897, it was 15°. The three nights of March 18, 19, 20, min. 19°, 21°, 17°. I need hardly say great damage is done to spring flowers. I have never before seen the flowers of Erythronium dens-canis quite destroyed by cold as they now are. *C. W. Dod, Edge Hall, Malpas.*

—— IN NORFOLK. — The calm, dry, cold weather which we have experienced throughout the month up to Saturday morning, 18th inst., gave way to strong winds coming from N. E. back to N. and N. W., with very cold weather. And snow fell frequently during Sunday and heavily at night, and on Monday at 6 P.M. there was snow to a depth of six inches; and the day remained cold, and there was less wind by 8.30 P.M. The thermometer fell to 24°, and by this morning it had fallen to 5°, thus registering 27° of frost, and at 6.30 A.M. 22° of frost —an unusual degree of cold for this part of the season. The day is fine so far, but the snow remains in shady places. *J. Batters, Gillingham, Norfolk.*

—— IN BEDFORDSHIRE.—An unusually low temperature was registered here this morning, March 22, which is likely to prove injurious to the most forward Gooseberries and Pears, though none of the latter have their blossoms expanded. We had a fall of snow yesterday to the depth of two inches, and this was followed by an exceedingly clear and still night. At the lowest part of the farm, a tested radiation thermometer on the ground recorded the minimum as minus 2·8°, or nearly 3° below zero, Fahrenheit. The elevation above sea-level is about 240 feet, and the position of the thermometer is near a watercourse. *R. L. Castle, Woburn Experimental Fruit Farm, Beds.*

EUCALYPTUS.—I think the interesting articles which have recently appeared in the *Gardeners' Chronicle* cannot have been seen by Mr. Bateman, the owner of a remarkable avenue of Eucalyptus Gunni on his estate at Brightlingsea Hall, near Colchester. I saw the trees in August, 1894, many of them being of large size and well-formed specimens. They appeared to be perfectly hardy, and had been growing outside for some years. I was told that the trees bloomed and seeded freely, and that some of the seeds were collected annually and sown in drills in the kitchen garden, and the seedlings pricked out in nursery lines, and finally planted in the woods, &c. If Mr. Bateman would kindly record his experience with this Eucalyptus, and state the size of his largest trees, I am sure many of your readers would be pleased. *G. W. Cummins, Balmedie, Aberdeen.*

NURSERY NOTES.

MESSRS. JOHN LAING & SONS.

The principal floral display at the present time in the well-known Forest Hill Nurseries, is due to the fine collection of Cliveias there cultivated. Of early spring-flowering greenhouse plants, none are more popular than the Chinese Primrose and the Cyclamen, and partly in consequence, both of these plants have been vastly developed in recent years. But the Cliveia, though its qualities are very different to those possessed by the Primula or Cyclamen, has nevertheless characteristics that make it valuable at this season. Among greenhouse plants it is essentially hardy, never requiring much heat, and seldom injured by exposure in a cold dwelling-room or to draughts. When potted in a moderately rich compost, the plants will thrive well for several years, and need not be repotted unless the pots are very full indeed of roots. Until this is the case, the plants remain perfectly healthy, and flower very satisfactorily upon occasional applications of liquid manure.

In regard to flowering, a single plant usually produces two spikes of bloom in the season, and occasionally three. The spikes carry upon an average from twelve to twenty-four blooms each, and they have been known to produce as many as thirty-six. If a single plant in an 8-inch pot will produce forty flowers per year, nothing more, it would seem, could be expected. Since the well-known C. (or Imantophyllum) miniatum was introduced to gardens, very many seedling varieties have been raised by Messrs. Laing and others, that vary in the tints and form of the flowers, and in the habit of the inflorescence. The petals are less pointed, more imbricate, and the corolla being more round, the flower has some resemblance in form to that of the Vallota purpurea. Such seedlings, with compact trusses of distinctly marked flowers, are undoubtedly very handsome and useful for decorative purposes as plants or as cut blooms.

In Messrs. Laing's collection may now be seen a number of these modern varieties, and of such the following are some of the best: W. P. Leech, bright red; Comet, Queen Victoria, Harry Laing, one of the very best; Fascination, Lord Rosebery, Fireball, Sunrise, Princess Frederick, a light-coloured one; Advance, Her Majesty, Lady Wolverton, &c. Miss Ellen Terry was not yet in good form, but the variety is a very choice one. Salamander, too, may be recommended as one of the best to date. As we have said, the varieties differ chiefly in tint of colour and in the form of the flowers, and these variations are most obvious when each can be compared with the other.

In other departments of the nursery, work is plentiful at this season. The tuberous Begonias, for instance, that bear so much evidence of the result of cross fertilisation, a work in which Mr. John Laing, senior, was the first to engage, are in various stages of growth. Seedlings have yet to be "pricked off," and thousands already so isolated are growing freely. The earliest plants are already vigorous specimens in 5-inch pots.

Writing of Begonias, reminds us of several varieties of Begonia semperflorens with double flowers. There were Boule de Neige, Triomphe de Lorraine, Nancy, &c. The varieties presented several colours, and appear to be as free blooming as the single-flowered ones.

In another house was a large group of Messrs. Laing's "multiflora" type of Streptocarpus. These plants were raised from seeds last season, and are just commencing to bloom in quantity. From white to exceeding dark purple, the flowers present a great variety of shades, and are all pretty.

The Caladiums already present a charming diversity of tints in the young and delicate foliage now being produced. That gardeners have need to be prepared for extreme variations in our much-discussed weather was instanced on the 14th inst., when our visit to Forest Hill was made. During the previous night there had been 18° of frost there. In the middle of March such severe weather is scarcely anticipated.

NEW INVENTION.

WECK'S STERILISER.

About three years ago I made the first experiments with the above method to sterilise fruit and vegetables in glasses. I chose Cherries, Plums, Mirabellas, and Pears, and the following vegetables: Green Peas, Beans, Carrots and Asparagus. The result was striking, for not only the sterilised garden produce, which was sent away in the middle of winter, was of the choicest quality and finest flavour, as if taken fresh from the garden, but also the relish was enhanced by the knowledge of having cultivated and reaped these products one's-self, and having put them into the glasses with the utmost care and cleanliness. Also there is no taste of metal in Weck's glasses, such as is always found in tinned goods. Another advantage is the cheapness of this method, when one's own garden produce is sterilised, because the amount of cost cannot be compared with the advantages gained in wholesomeness and cleanliness, especially when one bears in mind the fact that the same utensils last for years.

Consequently I introduced Weck's steriliser in a hospital here, where the nursing sisters have been busily occupied ever since in sterilising the produce of the hospital garden, in order to give it to the sick people who are under their care during the winter. Formerly the sick in this hospital were restricted to such fare as dried fruit and vegetables stored in the cellar, the hospital not being able to afford the expense of costly preserves. But now it is possible to provide the sick at any time with the choicest preserved fruit and vegetables.

Mr. Weck has made his apparatus in several sizes, and keeps the glasses, lids, and utensils belonging to it always in stock. The inventor is always willing to answer any questions, and to send recipes and prospectuses. Any of these articles can be obtained from Madame Alexandrine Veigelé, 87 and 89, Praed Street, Paddington, W. *Georg Kerner, physician, Wehr (Baden).*

CULTURAL MEMORANDA.

THE CLIVEIA.

Much has been done of recent years in improving and raising new varieties of this plant, and bringing them into notice. The cultural treatment the plant requires is of a very simple nature, and the immunity it enjoys from injurious insects, combined with its usefulness, should make it commonly cultivated. It is particularly an amateur gardener's plant, as it succeeds without much care being bestowed on it. I lately saw some plants of it, together with Vallota purpurea and Crassula coccinea, that were grown to great perfection by an amateur and his wife. Its natural season for flowering is in the spring and early summer months, but it readily responds to gentle forcing, and may thereby be obtained in flower in the winter, and its flowering season may be thus lengthened. For ordinary decorative purposes it may be grown in small pots, as then it may be pleasingly arranged in groups or amongst other plants, and small plants are well adapted for the dwelling-house. When cut-flowers only are wanted large plants should be grown, the flower-spikes being then more numerous, and the labour attendant on affording water is less. I cultivate numbers of large plants for this purpose, and find them very serviceable. The plant is easily increased from suckers or crowns, taken off when growth begins. To do this safely turn the plant out of the pot, and separate the suckers with roots attached, and pot singly in pots suitable to the size of the suckers; place in a warm, rather close greenhouse, giving careful attention in the matter of affording water, and syringing them daily after bright sunshine. The pots will be filled with roots by the autumn, at which season they should be afforded plenty of air and a drier atmosphere; during the winter place them in a cool greenhouse, and keep the soil tolerably dry. In the following spring when growth commences they will require a shift into larger pots. The Cliveia does best when its roots are pot-bound, therefore large shifts should be avoided. I once tried some planted out, near to the glass, in a warm greenhouse-border, but they did not do well, and were ultimately re-potted. Large plants may be preserved in a satisfactory state for years, without being re-potted, and they will burst their pots from this cause, and yet be in perfect health. Once they become pot-bound, manurial aids are necessary. As a potting compost, good fibrous loam mixed freely with sand and a small quantity of leaf-soil answers well, and the pots should be thoroughly drained. *Thos. Coomber.*

LAW NOTES.

ASSESSED TAXES.—TREEBY, NURSERYMAN, of OLD TRAFFORD, MANCHESTER.

We have received a copy of the correspondence which has passed between the solicitor to the Nursery and Seed Trade Association and the Board of Inland Revenue:—

"In consequence of the proceedings instituted against Mr. Treeby for omitting to take out a licence to keep a gardener, communications have passed between nurserymen in Manchester and the Nursery and Seed Trade Association, Limited. The decision in this case seems so far-reaching that it may affect nurserymen throughout the United Kingdom if a tax is payable by nurserymen in respect of their employing gardeners under the following circumstances.

"It is the practice of nurserymen to contract in writing with householders (whose gardens are not large enough to require the entire services of a gardener) to keep their gardens in order for a fixed sum per annum, and nurserymen for such purpose agree to send a gardener or gardeners for a day or several days or portions of a day in each week, according to the size of the garden and the season of the year. The gardeners so employed are engaged and paid by the nurserymen, are under their sole control, can be taken from their work, and others substituted, as the nurserymen wish.

"Skilled gardeners employed by London nurserymen are engaged, subject to receiving or giving a week's notice to leave; less skilled gardeners are engaged on the terms that they give or receive a day's notice, or a day's pay in lieu thereof. Both classes, when not engaged in keeping the gardens of householders in order, work in the nurserymen's grounds on general work.

"I submit that the statute 32 & 33 Vict. c. 14, sect. 19, applies solely to gardeners or under-gardeners engaged by private individuals for a certain period, and at a fixed salary in the same manner as a butler or under-butler, also mentioned in the statute, and not to gardeners employed by nurserymen on the terms above stated.

"A copy of a letter from the Secretary to the Chancellor of the Exchequer to Sir J. W. Maclure, Bart., M.P., has been supplied to me as solicitor for the before-mentioned association which was established in 1877 by some of the principal horticulturists to protect and promote the trade of nurserymen, florists, and seedsmen, and I have been instructed by the committee of management of such association to enquire whether your Honourable Board would, for the guidance of nurserymen, think right to inform me:—

"(1). Whether nurserymen who enter into contracts such as I have referred to, are required to take out licences for the number of gardeners they employ to carry out their contracts?

"(2). Whether, if a nurseryman contract with a householder (who does not desire to engage a gardener) to keep his garden, including hot-houses, in order by the year or for a shorter term, subject to determination by notice, and the work is sufficient to occupy the whole time of one man or more (the nurseryman being at liberty to send what man or men he likes to do the work) a licence for the gardener or gardeners so employed by the nurseryman is necessary?

"I am, yours faithfully, Charles Butcher, 30, Wood Street, Cheapside, London, Solicitor to the Nursery and Seed Trade Association, Limited."

"Inland Revenue, Somerset House, London, W.C.
March 14, 1899.

"Sir,—With reference to your letter of the 4th inst., I am directed by the Board of Inland Revenue to state, that as, so far as they are aware, the appeal in the case of Mr. James Treeby is to be proceeded with, they do not consider it convenient to discuss the liability of a nurseryman to licence duty in respect of gardeners employed by him and furnished on hire, upon any general basis.

"But if you have any specific case of a servant so employed and furnished on hire, upon which a question of liability to licence duty is raised, the Board will be ready to deal with it upon receiving the full particulars.—I am, Sir, your obedient servant, Aug. H. Browne, Assistant-Secretary."

"Charles Butcher, Esq."

Obituary.

Thomas Sibbald.—On March 17 last there passed away at Elm Bank, Bishop Auckland, at the age of seventy-two years, Mr. Thomas Sibbald, of the Escombe Nurseries in that town. The Sibbalds were of Scottish descent, and the founder of the Escombe Nurseries, Mr. Sibbald's grandfather, held distinguished office under the Bishop of the diocese, Dr. Shute Barrington, over a century ago. These nurseries have remained in the possession of the Sibbald family for more than three generations. The deceased, for more than forty years, had carried on an extensive business as nurseryman, seedsman, and florist; he was, moreover, a useful and prominent citizen, and had greatly helped in inaugurating or carrying out numerous works of public utility in Bishop Auckland. The business will be carried on by his son, Mr. T. Sibbald.

William Murray, of Parkhall Gardens. — We regret to record the death of Mr. William Murray, the gardener at Parkhall, which took place on Saturday, March 11. The deceased was sixty years of age, and for a period of thirty-three years he had been gardener to Mr. Livingstone, Learmonth. Few men in Scotland have attained so great an amount of success as a Grape and Tomato grower as the deceased for twenty years past. His exhibits of fruit, and of Grapes especially, have always been in the winning positions at the Edinburgh and Glasgow shows. His fame as a cultivator was widely known, and many visitors went to Parkhall to see the enormous crops of remarkably handsome bunches of Grapes. Last year the amount of the crop and the quality were equal to any previous season. The Vines, too, by fine firm wood and immense glossy foliage, testified to the skill of a master-hand.

Mr. Murray's talents and his zeal for the welfare of his fellows was widely known, and greatly appreciated throughout the district. Among local institutions, Mr. Murray was an able member of School Board at Muiravon Side (where his remains were interred on Wednesday, March 15). He leaves a widow and one son. The latter now represents the firm of Wm. Murray & Son, which was formed two years ago by renting a large portion of the extensive ranges of glass at Parkhall, and a number of acres of land for market purposes. *M. Temple, Carron, N.B.*

William E. H. Baker. — We regret to learn of the death on Monday morning last, after a protracted illness, of Mr. W. E. H. Baker, eldest son of Mr. W. E. Baker, proprietor of the Thames Bank Iron Co. Mr. Baker was a young man of great promise, and until stricken down some three years ago took an active part in the Upper Ground Street business, and was much respected by the trade.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

March 14.—*Present:* Dr. M. T. Masters (in the chair); Dr. Müller, Mr. E. F. in Thurm, and Rev. G. Henslow, Hon. Sec.

Dahlias Diseased.—Some roots were received from a nursery firm, with the following communication:—"First, we started our roots in the manner we have done for years with the best results—namely, on a hot bench, taking cuttings within three weeks of their insertion, and gradually lessening the heat as time went on. Secondly, the first batch this season was somewhat soft, and all failed; not, however, by damping off, but from the effects of the disease. Thirdly, last season we had magnificent strikes, but near the close of the season, the "spot"—as on the specimen sent—made its appearance, but was very limited. Fourthly, the bottom heat was maintained at about 70°, while the top was about 15° less. Fifthly, can the Tomato-disease have become incorporated with the soil, as Tomatos had been grown there; and has this any relation to the disease or cause of the trouble? Sixthly, all the roots were placed in comparatively new soil, although some of the old may have been mixed with it. Seventhly, the house is well aired, and the cuttings were firm when taken off. As to remedies, we have applied sulphur with satisfactory results; so far as it killed the fungus at the root and allowed fresh clean growth to be made, but it had no apparent effect on the cuttings. They went off by the score. We have hitherto been most successful in Dahlia cultivation, and have had misfortunes, too, but this disease completely baffles us. The result is the same, both with hard-grown forced exhibition roots, and those grown without forcing."

The following valuable report on the preceding was received from Dr. W. G. Smith, Yorkshire College, Leeds, to whom a vote of thanks was unanimously accorded:

"The Dahlia cuttings when received showed various stages of blackened discoloration, where they had been in contact with the soil, and also on the older leaves, especially where they joined the stem. Where the blackening was worst the tissues were filled with bacteria, and fungus filaments were present. After a few days in a moist chamber the cuttings became black and rotten; the bacteria were more abundant, and the fungus bore colourless spores of two kinds. Your correspondent suggests infection from Tomato-disease, previously present in the same house. We find that the two forms of fungus conidia (and only two are present) occurring on this Dahlia material are almost (but not exactly) identical in form with those figured by Mr. Massee (*Gardeners' Chronicle*, June 8, 1805) in connection with the Tomato 'sleepy disease.' Whether this is a coincidence or a connection, it is as yet too early to say. There is, however, little doubt that this Dahlia disease affects the cuttings in the same way as the above Tomato-disease. It has its origin in the soil.

"Remedies.—Your correspondent has tried sulphur in the soil with some good effect. No fungicide, however, will be so beneficial as—

"1. Fresh clean soil.

"2. Ventilation, as far as it can be given.

"3. To water the freshly-struck cuttings as little as possible till they form roots.

"4. To use boxes or pans which have been thoroughly disinfected, and to have houses and benches washed down with a limewash.

"In addition to these Mr. Massee recommends for the Tomato-disease, to mix as much lime in the soil as the plant will stand. How far these measures can be carried out must lie with the discretion of the grower." Dr. Müller suggested sterilising it by baking the soil.

Hybrid Narcissi.—Some specimens were received from Rev. C. Wolley Dod, with the following remarks:—"I send a spontaneous hybrid which has come in one of my flower beds. It is presumably N. pseudo-Narcissus var. minimus × N. cyclamineus. I also enclose specimens of the parents. I consider N. cyclamineus one of the best marked species of the genus. It is the only one which has the perianth almost sessile on the fruit. Mr. G. Maw once suggested to me that it might be produced by N. minimus × N. triandrus, but he overlooked this character—the tube of N. triandrus being very long. In the hybrid sent the tube is intermediate between that of the parents. The trunk of the perianth follows neither parent, being cylindrical, whilst that of N. p. minimus tends to be funnel-shaped, and that of N. cyclamineus is always ventricose and contracted towards the mouth. N. cyclamineus is a profuse pollen-bearer and seed-bearer, but the bulb, with me at least, is short lived, and requires constant renewal from seed. I have also observed in another bed a hybrid, N. cyclamineus × N. pseudo-Narcissus, of some larger variety. The developed tube and glaucous broad leaf belong with certainty to pseudo-Narcissus, though the perianth is completely reflexed, as in cyclamineus."

WARGRAVE AND DISTRICT MUTUAL IMPROVEMENT.

March 15.—An ordinary meeting of the above Society was held on the above date, Mr. W. Pope presiding. After the usual routine business—

Mr. T. Haskett, gr. to J. W. Rhodes, Esq, Hennerton, read a very practical paper on "Budding and Grafting," illustrating his remarks by prepared slips, buds, and grafts, and showing the manner in which the latter should be inserted. Directions were given for ensuring success in the three methods most largely practised:—Tongue-grafting, cleft-grafting, and saddle-grafting.

Mr. Coleby (Hon. Sec.) also read an instructive paper on "The Wars of the Plants, showing that plants carry on a kind of warfare, in which the strongest come out victorious. It was pointed out that the "survival of the fittest" is no meaningless term in the vegetable world. A long discussion took place on the papers, and Votes of Thanks were accorded to the readers. Messrs. Pope, Robbins, Greenaway, and Fullbrook exhibited Begonias, Cinerarias, Narcissi, and Azaleas respectively.

DEVON AND EXETER GARDENERS'.

March 15.—The subject discussed at the last meeting of the Society was "Chrysanthemums and their Culture, with Hints on Dressing, Staging, and Judging Cut Blooms," the essayist being Mr. G. Stiles, gr. to Miss Fripp, The Grove, Teignmouth.

The best time to strike cuttings for exhibition purposes, said the essayist, was in December; and in the case of sorts which are later in producing suckers, not later than February. Cuttings will strike readily in boxes of about 2 inches deep, containing light soil, and placed in a frame with a gentle bottom-heat of say 55° to 60°, keeping them as near the glass as possible, and sprinkling overhead with tepid water. In sunny weather they need the protection of a light shading. When the cuttings have become well rooted, and are potted off into small pots, give them a little heat to excite root-action, but afterwards the less coddling given them, the better.

Mr. Stiles subsequently described the necessary details in the cultivation of the plants during the spring and summer. If intended for exhibition, said the lecturer, the flower-buds must be selected between the end of July and the middle of September. When this has been done, all shoots produced subsequently should be removed at once. From the end of July until the blooms are cut, a little liquid-manure with every alternate watering will be beneficial. A good liquid-manure may be obtained by immersing a bag of fowls' dung and soot in a barrel of water. From the first week in September a bi-weekly dose of sulphate of ammonia is beneficial —about 4 oz. to 5 gallons of water.

Begin to dress the blooms when they are only half open, removing any malformed, crooked, or superfluous florets or hard centres, and Nature will then repair the loss by developing the symmetry of the flower. This applies to the Japanese varieties. Treat the incurved similarly, but see that the blooms are made to droop, or to hang to the side, for this helps them to fill up, and develop a close, full centre. The removal of defective petals should be gradual.

After giving directions for staging cut blooms, Mr. Stiles concluded by giving a selection of twenty-four Japanese and twelve incurved varieties, specially valuable for exhibition.

BRIGHTON AND SUSSEX HORTICULTURAL AND MUTUAL IMPROVEMENT ASSOCIATION.

March 16.—The monthly meeting of this Association was held at the School of Science and Technology on the above date, Mr. W. Balchin, Jun., in the chair, Mr. G. Miles, vice.

Mr. T. W. Sanders gave an interesting lecture upon the "Scientific and Practical Aspect of Plant Propagation," which he illustrated by diagrams. The different methods of propagation were dealt with in a practical manner, viz., by seeds, cuttings, leaves, grafting, budding, and inarching. The lecturer also fully explained the process of seed-germination, the length of time it took for various seeds to germinate, and the conditions that were most favourable to germination.

The lecture was much appreciated by a large audience, consisting of members and friends. A unanimous vote of thanks was given to Mr. Sanders for his lecture, and a short discussion followed.

CHESTER PAXTON.

March 18.—At this meeting, Mr. John Jackson was to have read a paper on "Vine Culture," but was prevented from doing so on account of illness. In his absence, Mr. John Taylor (Hoole Hall), and the Hon. Secretary of the Society, undertook to give short addresses on the Potato, both of which gave rise to a considerable amount of discussion.

The principal points dealt with were the cutting and sprouting of tubers before planting, the best manures to use, and the classes of soils best suited for successful culture; spraying with Bordeaux Mixture, as a means of preventing the spread of fungoid diseases; and the best varieties to use for successional crops.

Mention was made of the interesting series of Potato trials made at the Cheshire Agricultural School, under the direction of Mr. Gordon, Principal of that Institution, as an excellent means of ascertaining the best varieties to suit local districts A collection of some thirty-six varieties was staged, and those which found most favour with the audience were Up-to-Date, The Dickson, Sutton's Reliance, Mr. Breesee, Cheshire Prince, General Roberts, Snowdrop, and Clarke's Maincrop, which was admitted by all to be the best-flavoured late variety yet introduced, although not so heavy a cropping variety as some of the others.

Before the members dispersed, the President (Mr. John Wynne) proposed a Vote of Thanks to Mr. Taylor and Mr. Miln, which was seconded by Mr. Barnes (Eaton Gardens) who recommended Early Ringleader as the best and most profitable variety for pot-work and for early borders.

CORNWALL DAFFODIL AND SPRING FLOWER SHOW.

March 21.—The third show of this Society was opened in the Concert Hall, Truro, on Tuesday, March 21, under the very unusual conditions for Cornwall of most inclement weather, snow covering the ground. The occasion was made memorable by the visit of a deputation from the Royal Horticultural Society, consisting of the Rev. W. Wilks, Secretary, Mr. C. E. Shea, Rev. G. H. Engleheart, and Mr. G. Bunyard.

The show in every way maintained its reputation. Indeed the demands for space overtaxed the room at disposal. The large collection of Narcissi sent from Scilly by Mr. T. A. Dorrien-Smith, Mr. D. H. Shilson's magnificent Rhododendrons, and the several noble collections of flowering shrubs were the salient features of the exhibition, but the many collections of Narcissi, Violets, and other spring flowers staged by amateurs, were of high excellence. The deputation made the following special awards on behalf of the Royal Horticultural Society.

A Gold Medal to T. Algernon Dorrien-Smith, Esq., Tresco Abbey, Scilly, for a collection of more than 100 varieties of Daffodils "representative of the invaluable work done by him for the floral industry of Cornwall."

A Gold Medal to D. H. Shilson, Esq., for Rhododendrons, very many being of his own raising.

A Silver-gilt Flora Medal to Messrs. R. Veitch, of Exeter, for a collection of rare shrubs.

Silver Flora Medals to Messrs. Howard Fox for flowering shrubs; and John Nicholl for Bamboos, &c.

A Silver Banksian Medal to Robt. Fox, Esq., for flowering shrubs.

The following exhibitors were highly commended:—D. H. Shilson, Esq., for hardy spring-flowers; M. H. Williams, Esq., for flowering shrubs; J. C. Daubuz, Esq., ditto; Capt. Pinwell, for extraordinary specimens of Narcissus maximus; Andrew Lawry, Varfell, Mount's Bay, for Market Narcissi.

In declaring the show open, J. C. Williams, Esq., the President, welcomed the deputation and expressed the thanks of the local Society for their presence. He pointed out that they had come so far, out of no mere passing compliment, but hoping to recognise and encourage what was in truth a serious enterprise, namely the advancement of a worthy and profitable industry in Cornwall.

The Rev. G. H. Engleheart in his reply on behalf of the deputation, called attention to the manner in which the farming of flowers, fruit, and vegetables, was fast occupying the ground vacated by agriculture, and urged the importance of all localities specially favoured by soil and climate, making a full use of their advantages. Flower shows were no longer mere assemblies for amusement, but opportunities for amateurs and professionals to meet on common ground, and exhibit and ascertain all that is of the best. The past history of the Royal Horticultural Society itself was both a warning and an encouragement to local societies—there was a time when, perhaps, it overlooked its practical and proper work for what was mere fashion and amusement, but from the time that it had become a truly working horticultural society its success had been assured. Let this Cornish Society bear in mind that its shows were no mere pastime, but a sign of and an incentive to an actual work—the furthering of this great industry of the county, and it would go on from things already good to things even worthier.

The judges other than those representing the Royal Horticultural Society were Miss Willmott, F. W. Burbidge, M.A. and Mr. Ilott.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 9.—At a meeting held at the Coal Exchange, Manchester, on the above date, there were present Messrs. G. Shorland Ball (chairman), W. Thompson, T. Statter, A. Warburton, H. Greenwood, J. Leemann, G. W. Law-Schofield, P. Weathers, J. Cypher, R. Johnson, W. Stevens, J. Robson, and T. Mills, hon. sec.

W. THOMPSON, Esq., The Grange, Stone (gr., Mr. Stevens), showed Dendrobium Thompsonianum (nobile Cypheri × cheltenhamensis) (Award of Merit); and a group of Odontoglossums (Silver Medal).

THOMAS STATTER, Esq., Stand Hall, Whitefield (gr., Mr. Johnson), showed Cœlogyne cristata alba (First-class Certificate), Dendrobium splendidissimum grandiflorum (Cultural Certificate), D. s. giganteum (Award of Merit), D. nobile nobilius (Cultural Certificate); also a group of miscellaneous species and varieties (Silver Medal).

S. GRATRIX, Esq., Whalley Range (gr., Mr. McLeod), showed Dendrobium rubens grandiflorum (Award of Merit); D. Luna (Award of Merit), D. Wardianum album (Award of Merit), and Cypripedium Lebaudyanum (Award of Merit).

JOHN LEEMANN, Esq., Heaton Mersey (gr., Mr. Edge), showed Denbrobium Wardianum album (First-class Certificate), D. Ballianum, D. Sanderæ (Award of Merit), D. nobile albiflorum (Award of Merit), D. splendidissimum grandiflorum Thompson's var. (First-class Certificate), Cattleya speciosissima Princess of Wales (First-class Certificate), C. Octave Doin (Mendeli × aurea) (First-class Certificate), Lælio-Cattleya callistoglossa (First-class Certificate); also a very fine miscellaneous group (Silver-gilt Medal).

G. W. LAW-SCHOFIELD, Esq., New-Hall-Hey, Rawtenstall (gr., Mr. Shill), showed Dendrobium nobile giganteum (Award of Merit), D. n. Fisheri (Award of Merit), D. Doris (Leechianum × moniliforme) (First-class Certificate), D. euosmum virginalis (endocharis × nobile) (Award of Merit), D. dulce (aureum × Linawianum) (Award of Merit), Lycaste Skinneri alba (First-class Certificate), and Odontoglossum crispum virginale (First-class Certificate).

A. WARBURTON, Esq., Haslingden (gr., Mr. Lofthouse), showed a yellow variety of Cypripedium insigne (First-class Certificate); also a fine group of cut blooms (Vote of Thanks).

E. J. SIDEBOTHAM, Esq., Bowdon (gr., Mr. Shiner), showed Dendrobium Luna (Award of Merit).

HY. GREENWOOD, Esq., Haslingden (gr., Mr. Gill), showed Dendrobium Juno (First-class Certificate), D. Owenianum (First-class Certificate), D. Aspasia (Award of Merit), and Cypripedium Mastersianum (Award of Merit).

D. B. RAPPART, Esq., Liscard (gr., Mr. Nicholson), showed Odontoglossum crispum (Award of Merit).

Mrs. BRIGGS-BURY, Accrington (gr., Mr. Wilkinson), exhibited Dendrobium × Hebe (First-class Certificate), Odontoglossum Ruckerianum (Award of Merit).

O. O. WRIGLEY, Esq., Bury (gr., Mr. Rogers), had Cypripedium insigne, Harefield Hall var. (First-class Certificate), Cypripedium seedling (Curtisii × barbatum) (Award of Merit).

R. ASHWORTH, Esq., Newchurch (gr., Mr. Pidsley), showed Lycaste Skinneri alba, bearing thirty-three expanded blooms (First-class and Cultural Certificates).

E. STANLEY CLARKE, Esq., Wrexham (gr., Mr. Edwards), showed Odontoglossum crispum Mrs. Stanley Clarke (Award of Merit), and a group of plants in flower (Vote of Thanks).

HY. WEETMAN, Esq., Glossop (gr., Mr. Faulkner), had Dendrobium nobile Amesiæ (First-class Certificate).

EDWARD HOLT, Esq., Prestwich (gr., Mr. Murphy), staged a group of miscellaneous Orchids (Vote of Thanks).

Messrs. J. VEITCH & SONS, Ltd., Chelsea, exhibited Dendrobium Ainsworthi intertextum (First-class Certificate), D. A. i. amœnum, D. euosmum leucopterum (Award of Merit), D. e. delicatum (Award of Merit), &c.

Messrs. F. SANDER & Co., St. Albans, showed two forms of Cattleya Trianæi, one of which received an Award of Merit, and other plants.

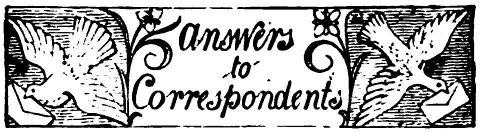
Mr. A. J. KEELING, Bingley, showed Odontoglossum Wilckeanum superbum (Award of Merit and Cultural Certificate), O. Andersonianum virginale, and Dendrobium splendidissimum grandiflorum, Thompson's var. (First-class Certificate).

Mr. JOHN COWAN, Gateacre, showed Cattleya Trianæi Archleana.

Mr. JOHN ROBSON, Altrincham, showed Cymbidium Lowi-eburneum (Award of Merit), Dendrobium xanthocentrum (Award of Merit), and a group of other plants (Vote of Thanks).

Mr. J. CYPHER, Cheltenham, staged a group of miscellaneous Orchids (Vote of Thanks).

THE ROYAL GARDENERS' ORPHAN FUND.—The smoking concert in aid of this Fund, held on the 15th inst. at Cannon Street Hotel, was very well attended, but the proportion of gardeners to those present was exceedingly small.



Answers to Correspondents

BOOKS: *A. D. B., Jena.* *The Encyclopædia and Dictionary of Gardening*, by Geo. Nicholson and others, in the English language, first edition, by Mr. Upcott Gill, 170, Strand, W.C.; or the newer French edition of the same work (*Dictionnaire Pratique d'Horticulture et de Jardinage*), par G. Nicholson and S. Mottet; Vilmorin-Andrieux et Cie., published by the Librarie Agricole de la Maison Rustique, 26, Rue Jacob, Paris.—*Jason.* Horticultural Buildings, by F. A. Fawkes; published by Swan, Sonnenschein, La Bas and Lowrey, Paternoster Row, E.C. New edition, *Heating by Hot Water*, by Walter Jones; published by Crosby Lockwood and Son, 7, Stationers' Hall Court, E.C. 2nd edition.—*B. R.* The most recent work on landscape gardening is the one under that title, by Mr. Samuel Parsons, published by G. P. Putnam's Sons, 27, King William Street, Strand, W.C.

CABBAGES, BROCCOLI SPOILED: *J. S.* The plants are affected by a slime fungus, the cause of clubbing and other ills in Brassicas. Try heavy liming the soil and fallowing as far as may be practicable, and varying the cropping, that is, not planting any Brassicas on the same piece of land two years running. The land should be trenched, not necessarily bringing the bad subsoil to the top, but breaking it up and leaving it at the bottom. Some of it may be brought up at the next trenching, say, in three or four years. As the soil appears to be full of manure or vegetable remains, the lime will benefit it, and some may be applied at every winter digging for some years to come.

CORRECTION.—The Snowdrop figured in our last issue under the name Cassalia should be called "Cassaba."

CUCUMBERS: *E. S.* The roots are badly affected with the eel-worm, so often described in these columns. There is no cure, but you should burn the plants, get fresh soil, and bake it before using to kill the worms in the soil, and start afresh.—*J. L.* Probably eel-worms. Can you send a few roots for our inspection?

DONATION: *G. King.* We make no charge for such insertions, and we have forwarded the Postal-order to the Secretary of the Royal Gardeners' Orphan Fund.

EXPANSION-JOINT IN HOT WATER PIPES: *G. A. K., Mount Tolmie, Victoria, B.C.* This kind of protection against fracture by internal pressure is not in use here, the feed cistern answering the purpose. With steam heating and cast-iron pipes it is necessary, and it usually consists of a sliding length of pipe accurately turned and smooth, inserted between the disconnected ends of the main steam flow.

FIGS: *W. J. G.* The fruits of the Fig fall off when young from a variety of causes—from lack or from excess of water, from cold, or check of any kind; from being too forward at the period of rest, &c. A "well drained" border is liable to become very dry when least suspected, and in the absence of any details of cultivation in your note, we are unable to indicate the cause of the fruit dropping. It is not good practice to stop the shoots "several times"—at the least, not the same shoots, in the summer.

GENISTAS: *Swiss.* The usual time to strike cuttings of the greenhouse species is the end of June or the beginning of July. They should be slips taken off with a thin heel and put into 32's or 48's, filled with sandy peat made firm, and surfaced with ½-inch layer of silver sand. The pots must be well drained, with quite small crocks two inches deep. The cuttings must be covered with a bell glass, which must be wiped daily. A greenhouse temperature, and shading from bright sunshine, must be afforded. Stocks for forming standards may consist of the slender growing C. filipes.

GRENADILLA SEEDS: *A. W. P.* The seeds should be sown in finely-sifted loamy soil, with one-sixth leaf-mould and some silver sand incorporated, covering them to the depth of a quarter of an inch with the soil. The seed-pots should be well drained by placing a two-inch layer of finely-broken crocks at the bottom over one large convex piece placed over the hole in the pot. When afforded water, stand them in a mild hotbed or intermediate-house, and when the seedlings have made a true leaf or two prick them off into other pots in warmed soil, and finally pot them up and grow in a warm part of a greenhouse. A roughish soil, consisting of loam, leaf-mould, or fibry peat and decayed manure one-fourth, will suit the plants when they are a year old, affording them good drainage and a warm situation.

LAPAGERIA: *Swiss.* The layering may be performed in the spring by pegging down the shoots on a bed of peaty soil, and covering them at the nodes where the pegs are situated about one inch deep.

NAMES OF FRUITS: *George Farmer.* 1, Striped Beefing; 2, not known; 3, Lane's Prince Albert. Samples sent much rubbed and discoloured; they do not fairly represent the proper character at this season.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—Armitage, Bros.* Chorizema cordatum.—*E. S. R.* Probably Pinus Tæda. Can you not send us a cone?—*P. P.* 1, Ophiopogon Jaburan variegatum; 2, Cestrum (Habrothamnus) species; 3, Bilbergia nutans; Nos. 4 and 5 have not come to hand. The Shamrock should be planted out of doors; and the Swainsonia have the dead wood removed and the new growth stopped once.—*F. C.* 1, Coronilla glauca; 2, Streptosolen Jamesoni; 3, Pilea muscosa.

NUT BUSHES SEVERELY CUT BACK: *E. S.* The clustering shoots, the result of the operation, must be removed in great part, leaving only the best placed, only two or three as may seem desirable to form a new head. Nature would do this thinning out by the smothering out of existence of the weaker shoots, but it would be a lengthy process. The shoots that are left should not be topped this but next year, and during the summer young shoots not wanted must be rubbed off.

RICHARDIA AFRICANA: *Jason.* The production of early spathes is favoured by pot culture alone, but for late winter and spring-uses out of doors cultivation in rich, cool, moist soil with early potting may be recommended. Where early spathes are looked for, the plants should be turned on their sides when the leaves begin to yellow, and no water be afforded for two months, unless the pots be less than 10-inch. See a remark by a correspondent in our Home Correspondence in the present issue.

ROLLER BLINDS FOR STOVE: *R. C. D.* Undoubtedly the best are made from thin Bamboo splints, secured by copper wire. They should be made 5 feet wide, and as long as may be necessary. Sold by some of the horticultural sundriesmen.

WILD RED CURRANT: *G. A. R., Mount Tolmie, B. C.* We should question an Alaskan wild species being as good as our garden varieties.

THE
Gardeners' Chronicle
No. 640.—SATURDAY, APRIL 1, 1899.

THE TEMPERATE-HOUSE AT KEW.

WE record with pleasure the completion of this magnificent plant-edifice, which will be thrown open in its entirety to visitors to Kew on Easter Sunday. It is exactly forty years since Mr. Decimus Burton supplied the designs which, with slight modifications, have been followed in the construction of, first, the octagons in 1861, the grand centre in 1862, the south wing in 1897, and, finally, the north wing in 1898.

The need of such a conservatory was urged by Sir William Hooker so early as in 1856, "for the accommodation of those noble Chilian, Mexican, and Australian Conifers, and other trees and shrubs of temperate climates, for the possession of which Kew has long been celebrated, but of which I must now speak almost in the past tense. . . . What is really required to render the Gardens complete, is as much accommodation for the large trees and shrubs of temperate climates as was granted for tropical plants twelve years ago, in the erection of our noble Palm-house, which is the pride and glory of our gardens, and then, and not till then, we shall have attained to all that this great national establishment ought to be." Sir William Hooker only saw part of his grand scheme carried into effect. His successor, Sir Joseph Hooker, appears to have relinquished all hope of ever obtaining funds for the erection of the wings, as he found "so many other and more urgently needed works to be carried out, especially in the Arboretum."

About five years ago, the Right Hon. Joseph Chamberlain, a frequent visitor to Kew, interested himself in the present Director's desire to see this building completed, and it was in great measure due to his exertions that a grant was obtained for the erection of the southern wing, and afterwards of the northern.

The house is now by far the largest plant-structure in the world, its length being 582 feet, its greatest width 138 feet, height of the grand centre 60 feet, of the wings 38 feet, and its ground area nearly 2 acres. The cost of the whole edifice has been about £60,000.

The value of such a house in a botanical establishment such as Kew cannot easily be over-estimated. It affords ample space for the proper development of the many interesting shrubs and trees of temperate and subtropical regions, which, in the plant-house of ordinary dimensions are cribbed, cabined, and confined in pot or tub, and are necessarily decapitated or mutilated to keep them within bounds. Such examples have little or no interest either for the botanical student or the horticulturist. "A botanic garden is not valuable as was once thought in proportion mainly to the number of species of plants which it contains, but to their characteristics, botanical or otherwise, their usefulness and beauty. Selection, rather than a collection, has become a necessity. Many plants that were formerly considered worthy of cultivation, simply because of their rarity, are now properly confined in the state of dried specimens to the herbarium." It is only when collections are formed and kept up on these lines that botanical gardens are made really attractive and useful, and when once we grasp the principle that a dozen well-grown, properly-developed plants are in every way preferable to fifty half-starved, miserable-looking examples, we shall have made an important step in the direction of improvement in glasshouse-gardening.

Large plant-houses are, however, likely to be a curse rather than a blessing if not constructed with a view to affording those conditions required by the plants it is intended to grow in them. It would be futile to attempt, for instance, the cultivation of a collection of Orchids or Ericas in this large house at Kew; and we are pleased to notice, by the way, that the reduction in the height of the Orchid-houses in the same establishment has already resulted in considerable improvement in the health of the collection. There can be no doubt as to the suitableness of the conditions afforded in these new wings of the Temperate-house for the plants grown in them, the growth made by almost every plant in the south-wing, known as the Mexican-house, being all that could be desired. A full account of the arrangements in and contents of this house was published in our pages in October, 1897, p. 234.

The north wing is to be known as the Himalayan-house, the majority of the plants to be grown there being natives of that region, or of China and Japan. The arrangement of the beds is exactly the same as in the Mexican-house, with the addition of two rock-pools near the north entrance, and two rooteries at the other end. No artificial heat is to be used, even in winter, the object being to show what plants can be grown in a large glass structure without fire-heat. The plants already planted there are:—Rhododendrons from the Himalaya and Yunnan, Camellias, Himalayan Bamboos, Tea, Magnolias and Talaumas, Indian and Chinese Roses, Buddleias, Vacciniums, Tree Pæonies, Arisæmas, Liliums, Kakis, Fatsias, Eriobotrya, Gordonias, Kumquat, Photinias, Nandina, Akebias, Eukianthus, Ligustrum coriaceum, Incarvilleas, Euonymus, Viburnums, Pueraria Thunbergi, Corylopsis, Osmanthus, Aralias, Himalayan Rubi, &c. Indian Nymphæas and other aquatics will be grown in the rock-pools, and some of the coarser herbaceous plants, such as Primulas and Saxifragas, will find a place either beneath the shrubs or in the chinks of the rocks. Eremurus will also be tried there. A few western plants have been admitted, only because the conditions of the house are peculiarly adapted to them; these are Carpenteria, Embothrium, Philesia, Fremontia, and a few others. Tall plants of Bambusa mitis will form an avenue along the central path, corresponding to the avenue of Cocos plumosa in the Mexican-house. So far the plants generally have taken kindly to their new quarters, notwithstanding the great size of many of them.

The general plan of the whole edifice is now as follows:—Plants requiring an intermediate temperature in the Mexican-house, temperate Eastern plants in the Himalayan-house, Oranges in the south octagon, Bays, &c., in the north octagon, and trees and shrubs of Australia, New Zealand, South Africa, and southern Europe in the grand centre.

The whole of the plants are planted out in long parallel beds, level with the paths, save only those which stand on a narrow bench extending all round the central part, and serving as a screen for the hot-water pipes. It is this natural arrangement which makes this house so much more pleasing than the Palm-house, for instance, where many of the plants are grown in pots or tubs necessarily huddled together, and standing on iron gratings over hot-water pipes, which, both in appearance and in effect on the health of the plants, are not unlike a huge gridiron.

We have almost reformed away from the outdoor garden that muddled arrangement once known as a shrubbery, and have substituted a looser, meaningful style, which gives each plant plenty of room to show itself to advantage. There is no reason why the same reform should not be extended to the glass-house garden, and we are glad to see such a reform has been carried into effect at Kew.

Whilst admiring, as all must do, the superior charm and beauty of plants grown under more natural conditions, it is nevertheless still essential in a botanic garden, especially at Kew, to have representative collections. Thus, at Kew, in addition to the monster palaces of glass, where after all only a limited number of species can be grown, we have, very properly, special houses for Orchids, Nepenthes, Ferns, Succulents, and the like, so that the student has the opportunity of seeing as complete collections of certain groups as circumstances will allow.

A spacious alpine-house and the formation of a rockery, under a removable glass roof, is a desirable feature, which we may hope to see at Kew in the future.

Again, following the analogy of the exhibitions of the pictures of Rembrandt and other masters, we should like to see at different times special collections of particular groups; such collections to be made as complete or as representative as possible, and to be retained unbroken for a few years, in order to give students the fullest possible opportunity of seeing the plants in growth. At the end of the time, the collections might be dispersed, retaining only the best for educational and ornamental purposes, and consigning the rest to the herbarium or to the rubbish-heap, as might be found desirable. In the herbaceous ground a similar plan might be adopted.

ORCHID NOTES AND GLEANINGS.

CATTLEYA TRIANÆI GIGANTEA, HAREFIELD HALL VAR.

THIS noble form of Cattleya labiata Trianæi has again flowered in the collection of Elijah Ashworth, Esq., at Harefield Hall, Wilmslow. The plant, which has unusually tall and stout growths, was collected in the Popayan district by Consul F. C. Lehmann in 1896, with the recommendation that out of the thousands of Cattleyas which he had seen in bloom in their native homes, this was by far the best in every respect. When it flowered at Harefield Hall, all the orchidists who saw it agreed that the recommendation was a just one when applied in comparison with home-grown specimens; and now, with the evidence of the flower sent by Mr. Ashworth, I can do no less than add my testimony. In the form of the individual parts, in their charming arrangement, in the fine thick substance of the flower, and its exquisite colouring, it leaves nothing to be desired. The broad flat sepals are silver-white, delicately flushed with a slight tinge of rose. The petals are each 4 inches long by 3¼ wide, silver-white, with a delicate tinge of rose, the colour being slightly more pronounced on the veining and the tips than on the other portion. The margins of the petals and the lip are very finely crimped and slightly fringed. The lip, whose circular front is 3½ inches across, is white at the base of the tube, up the centre running a band of orange-coloured markings, the band diverging to each side as it approaches the mouth of the tube. The middle area is bright rose-crimson, changing to pure dark rose as it reaches the margin. The outsides of the side lobes are rose-pink. Compared with this, most of the other named varieties would appear to a disadvantage. *James O'Brien.*

FORESTRY.

THE HOME NURSERY.

(*Continued from p.* 164.)

We may take it for granted that the class of trees or plants which the forester is most desirous of raising in the nursery are those which will bear transplanting with safety. The aim of the nurseryman is in a similar direction, no doubt, but pecuniary considerations compel him to study the rate of growth, as well as the transplanting capabilities of the plants he raises; and therein lies the chief difference between the management of home and commercial nurseries. In these latter, manure, and plenty of it, is usually relied upon to stimulate a strong and vigorous growth; and the usual paragraph in catalogues, that "our" nurseries are situated so many feet above sea-level, or freely exposed to this or that wind, may be taken for what it is worth. No doubt altitude and exposure do affect the growth of a plant, but how much or in what way it affects its transplanting capabilities, or its success in its future home, are not easy questions to settle. If we accept the Darwinian theory of adaptation to environment, the nearer a tree and its ancestors have lived to the spot which it is intended to permanently occupy the better. The chances are that the vicissitudes of local climate will be more easily borne by such a tree than by one which has to discover the local spring and summer for itself, or is compelled to work on data gathered in another place. Experiments carried out with seeds and seedlings tend to indicate that seeds or plants transplanted to a warmer climate than the one in which they have been grown or raised, start more quickly into growth than those indigenous to the locality. This may or may not be an advantage, according to circumstances, and within certain limits, may have no practical significance. In my opinion, by far the most important quality in a tree or seed intended for transplanting or sowing is a thoroughly ripened condition, and so far as seeds are concerned, nothing further need be said. With regard to trees, it is only necessary to consider what takes place when a tree is transplanted under ordinary conditions in order to realise the importance of its wood being thoroughly ripe, and well matured. In ordinary practice, and in ordinary language, transplantation means interrupted growth of either roots or stem. When transplanted in winter, as is usually the case, the growth of the roots only is directly interfered with, and this is effected by exposure, killing in the process of lifting, breaking off the growing points of the roots with their food-absorbing root-hairs. A plant cannot be said to be successfully transplanted, therefore, until this injury is repaired by the formation of new roots, and for this purpose the stock of reserve material stored up in the tissues of root and stem must be drawn upon. Plants lifted with the majority of their roots intact, and replanted before they are exposed to dry air or wind, probably suffer no more demand upon this reserve store than would be the case if the plant had never been moved, for root-growth goes on more or less throughout the winter at the expense of this store. But in the case of ordinary transplanting, such as takes place when plants are obtained from a nursery, and subjected to the usual processes of lifting, bundling, packing, or loading into trucks, transference by rail and road, &c., the roots die back a considerable distance from their extremities, and the roots it forms afterwards are practically, if not theoretically, adventitious roots. It is obvious, therefore, that a well-ripened stem and root, with an abundant supply of reserve material, is in a better position to form a new set of roots, and enable the plant to regain its normal condition, than a similarly treated root and stem in which this material is reduced to a low ebb, by reason of a shortened ripening period in the preceding autumn. *A. C. Forbes.*

(*To be continued.*)

SPRING FLOWERS.

Lonicera Standishi. This is one of the earliest flowering species of this genus, if not the earliest of all; it opened its flowers this year on March 16. The pale yellow, almost white flowers have a very fine perfume. The flowers appear before the leaves.

Chionodoxa sardensis. Amongst the early flowering bulbous plants, I know no other so lovely, so freely flowering as is Chionodoxa sardensis. Certainly its sister, the well-known Chionodoxa Luciliæ, is a fine plant, but its flowers with the large white stars are too pale a blue. Chionodoxa sardensis, though it has rather smaller flowers, is much more effective, owing to the darker blue colour of the blooms, which form a large many-flowered inflorescence that may be compared with that of Scilla bifolia, which blooms at the same time or a few days later. But these are larger than the Scilla flowers, from which they also differ from the first by their deeper blue colour; those of Scilla bifolia, the first day after opening, are of a greyish-blue hue which darkens afterwards.

Eranthis cilicicus, of which I gave a short description in the *Gardeners' Chronicle* last year, is a good introduction into our gardens. It flowers earlier than our Eranthis hiemalis, and the flowers are much more lasting than those of the old species. In my garden E. cilicicus began to flower this year the first week in January, and is to-day, March 20, still in bloom. The difference between the plants is but small, but the leaves are somewhat more finely divided in E. cilicicus than in E. hiemalis. The flowers of E. cilicicus vary in size so much that some flowers are almost double the size of others.

Galanthus cilicicus Baker, of which the *Gardeners' Chronicle* gave a description and figure last year, proves to be an excellent acquisition. It flowered here from October till March in the open air, as well as in pots in the cold greenhouse. Certainly it will become a good market plant, as Snowdrops at Christmas fetch a very good price. The flowers are larger than those of Galanthus nivalis, though they did not yet reach the size of those grown in their native locality. In other respects the other's appearance is just the same as that of Galanthus nivalis. *Dr. U. Dammer, Berlin.*

THE ROSARY.

IN THE ROSE-HOUSE.

There is no more busy or anxious time than the present among Roses under glass. The majority of the plants are now at the most susceptible stage of growth, and need great care and attention if mildew, insect pests, and other troubles are to be avoided. How often we find the tiny flower-bud turn a brownish-black while still no larger than a Pea. Excessive drought for an hour or two, or extreme changes of temperature, will often cause this. But I find the most prevalent cause of this to be careless fumigation. Fumes which will not seriously injure or cripple the youngest foliage, will often kill the tiny flower-bud. The most sensitive variety of all in this respect is Niphetos. I would never rely upon fumigation alone for the destruction of insects, but use it in conjunction with a weak solution of some reliable insecticide. The latter will be useful as a wash, at the same time that it disposes of the half-killed insects. Strong measures will not do with the tender foliage of Roses under glass, for even if injury is not apparent at once, the check has been given, and the results are inferior. Roses enjoy a syringing upon bright mornings, and it is just as well to use a very weak insecticide at the same time. This will check insects, keep the plants clean, and serve the purpose of necessary moisture. Our worst foe at this season is mildew. This is much encouraged, if not actually caused, by extremes of any kind. A check to young growth, whether from the roots on top of the plant, is almost sure to induce mildew. It throws the plant out of health, and this insidious disease gains a strong holding in an astonishingly short time. Draughts and sudden changes of temperature are the most fruitful sources of attack, and must be avoided. It needs great care and attention to give ventilation to the best advantage, when we are having bright sunshine with a keen wind and severe frost.

I believe Roses are often over-potted, and that not sufficient use is made of liquid-manures. Good as many of the chemical foods are, I prefer the drainings from a cow-stall, or stable even, to any of them. Give it in a weak state, but frequently. Where Roses are planted in borders, such varieties as Maréchal Niel, William Allen Richardson, and Gloire de Dijon, to climb over the roof or back wall, loosen the surface-soil, and give them a thorough soaking of liquid-manure. One needs to use a little judgment here, for the surface-soil is no guide to the condition of that where the roots of the Rose-trees may be. Never half-water a plant. *A. Piper.*

FOREIGN CORRESPONDENCE.

A GERMAN METHOD OF CLEANING TOMATO SEED.

Although interesting to read the different methods for cleaning this seed, none seem so simple or easy as that used here in Erfurt. By following the instructions as here given, the seed can be cleaned at very small cost of labour. The pulp, being scooped out, is placed in a sieve, the mesh of which does not allow the seeds to pass through. The sieve is then placed in water, and the pulp is rubbed through the mesh of the sieve by means of the hand. In a short time, the pulp all being rubbed away, the seed remains perfectly freed from it. In the same way Melon and such seeds may be cleaned.

GARDENERS' WAGES IN GERMANY.

Having regard to the frequent complaints one hears as to the "starvation wages" received by our English gardeners, I think it may interest you to know what one earns in Germany. At one of the largest and richest nurseries in this important town of Erfurt, the workmen (distinct from improvers) receive 10 to 15 marks weekly (a mark is about equal to a shilling). Only the best workmen receive as much as 15s. weekly, and a man twenty-five years of age with a family will only receive 11s. 8d. weekly to commence, and his wages will increase yearly at the rate of 8*d*. weekly. Then the average weekly money earned by these poor fellows is 13*s*. 6*d*.; and although living is cheaper here, they certainly have to be more careful than their English brothers, who earn nearly half as much again. Improvers are paid at the rate of 44*s*. monthly, rising half-yearly at the rate of 3*s*. monthly. Is it surprising that England cannot compete with Germany in seed-growing, considering the matter of wages alone? It is to be wondered, considering the low shipping rates, that Germany does not send us more than she does in the Rose and fruit-tree growing lines. *L. J. Cook.*

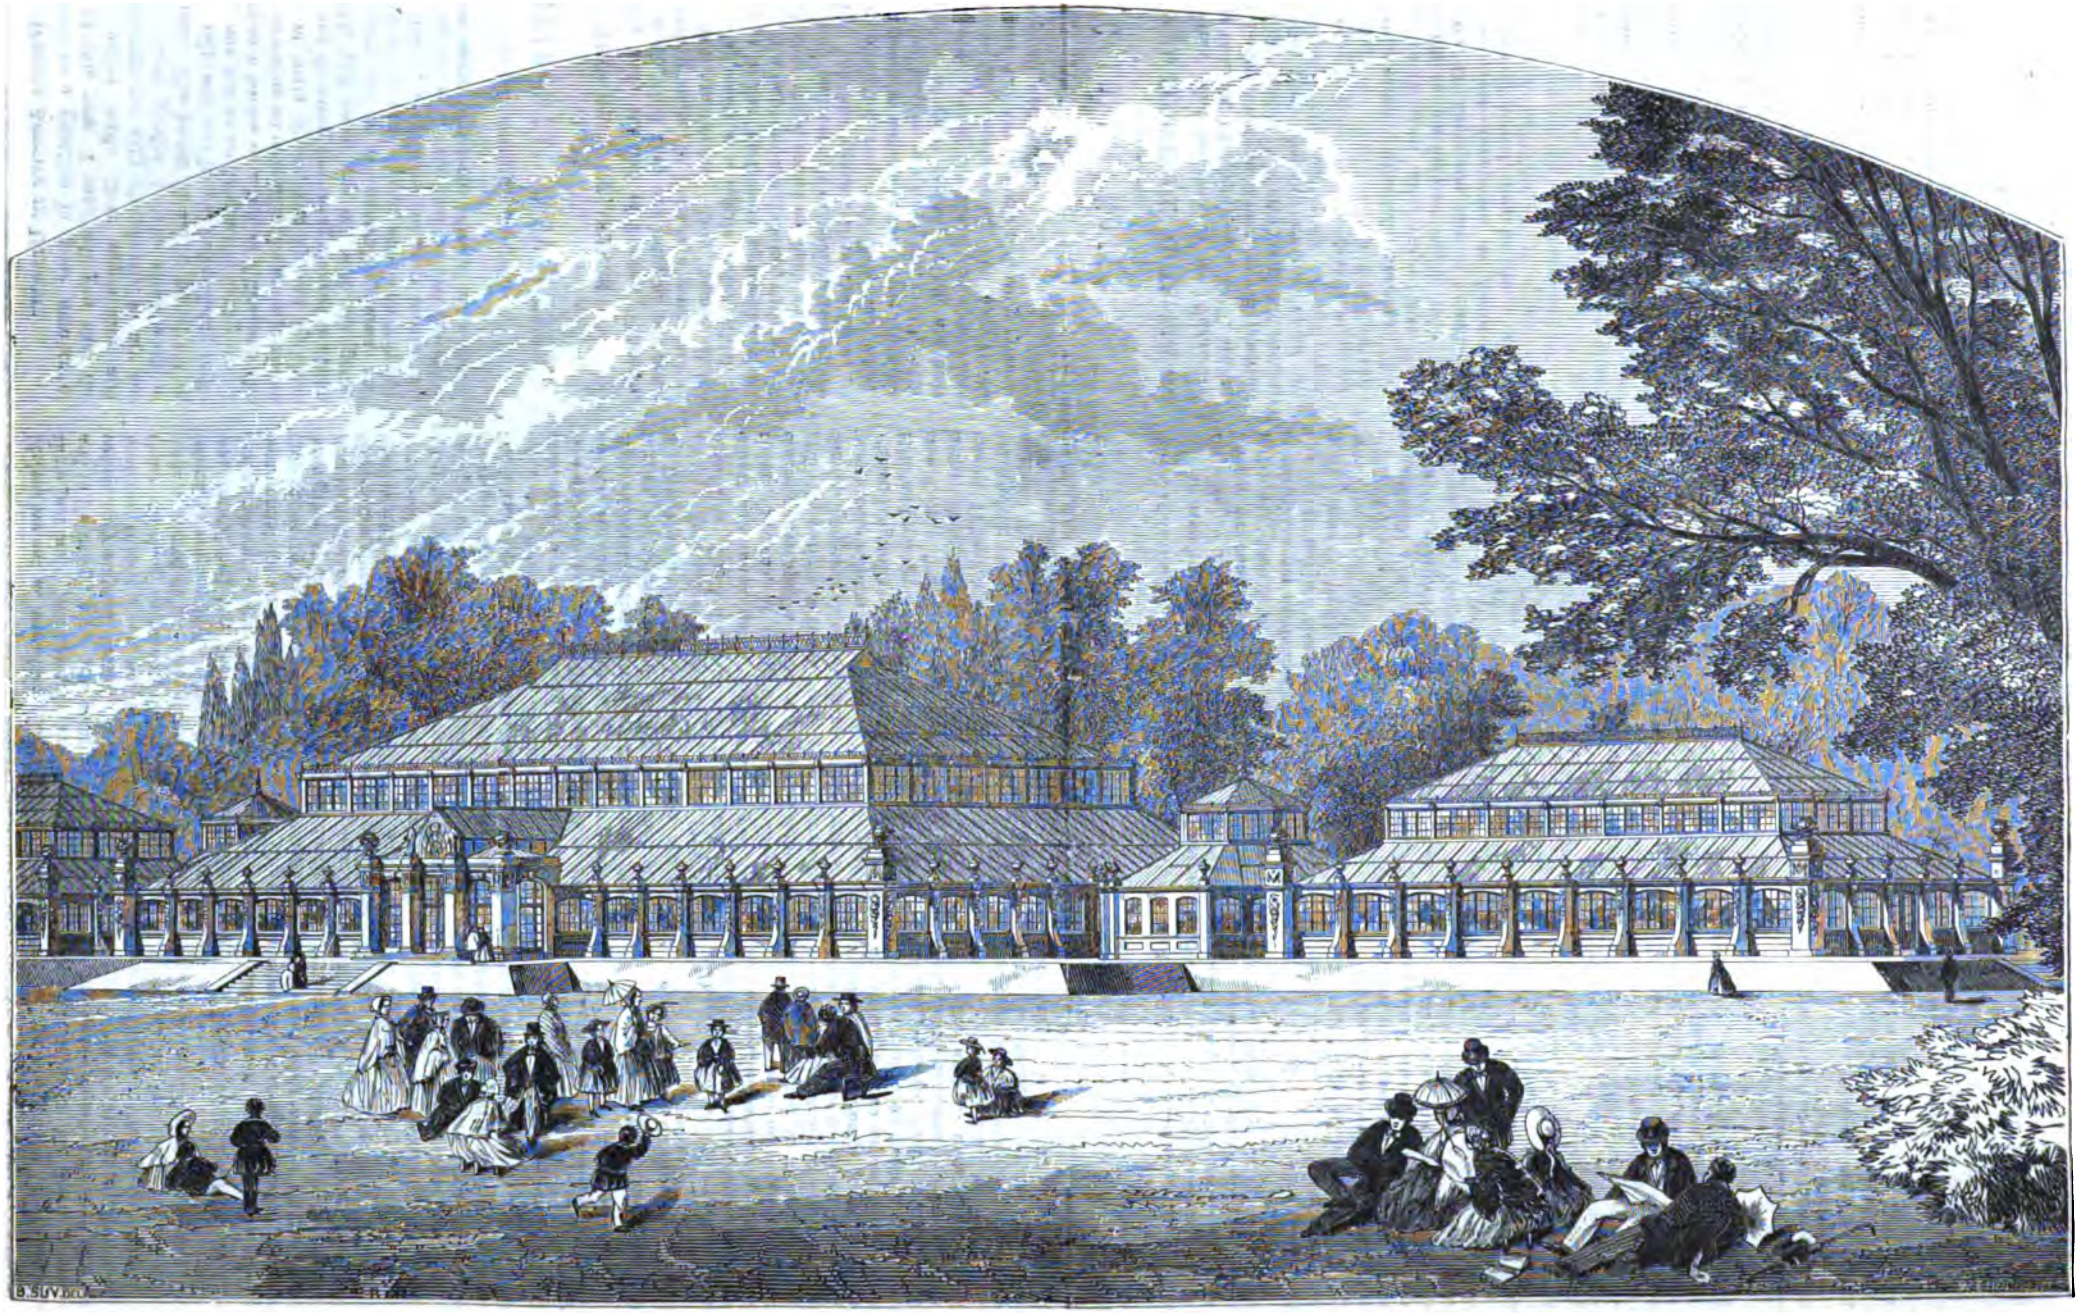

FIG. 73.—TEMPERATE-HOUSE, ROYAL GARDENS, KEW: EXTERIOR VIEW. (SEE P. 193.)

Winter Aconite in Utrecht.

In answer to a question in your number of January 14 this year, I may tell you that the Winter Aconites made their appearance and bloomed, though not very abundantly, in my not very large town garden in the third week of January last. The leaves should be permitted to die off entirely, and not be cut before being quite ripe, else there will be no flowers the next year. I have them as a border of a bed of Lilies, and the ripe seed spreading all around in the grass produces quantities of little plants, but by and by these disappear and die away, not being allowed to attain full growth, and being cut off with the grass. Aconites seem not to be generally known and appreciated at this time. In an article on "Spring Flowers," lately, they were not even mentioned, and yet they are so lovely, and the first flowers to bloom, even before Snowdrops. *Mrs. C. B., Utrecht, Holland.*

CONTINENTAL NOVELTIES.

NEW RACE OF ASTERS.

We learn from the list of Messrs. Vilmorin, Andrieux & Co. that they are bringing out some Asters which promise to receive a good deal of attention from gardeners. One named Reine Marguerite Japonaise is a needle Aster, which in habit belongs to the Perfection pyramidal class. The blooms, of a fine rose, are globular, with upright rays, which are twisted round on both sides. The stalk is strong, and capable of holding the bloom horizontally. At the present time the tints are light pink, rose-pink, red, pale blue, and white. The second race was noticed in the *Revue Horticole* in 1894. The blooms are large, very full, with numerous rays of great length, which are bent about the middle, giving the bloom the appearance of a Japanese Chrysanthemum. The colours obtained in this race are chamois-red, coppery-rose-red, coppery-red, and violet.

COLONIAL NOTES.

FRUITS AND FLOWERS IN QUEENSLAND.

I was very glad to read in the *Gardeners' Chronicle* of Oct. 29, 1898, that Mr. J. W. Miller, of Ruxley Lodge Gardens, Esher, is still growing William Tillery Melon. I brought this and several other varieties from England when I came out here, and it succeeded best of all. I was unfortunate in losing it for want of a place to plant one year. No seeds here that I have had to deal with will retain their vitality more than one year. Two applications to English nurserymen have been made for it, but in neither case was it true. My old friend, Mr. D. Thompson, late of Drumlanrig, sent me two sorts—Conqueror of Europe and Champion—but neither of them has done so well. I once grew a fruit of William Tillery under the influence of the electric light at Sherwood (where I lived with the late Sir W. Siemens) 11 lb. weight. There was but one fruit on the plant. We have plenty of fruits; but, with the exception of the Mango, which is very delicious, the Melon is our favourite. We have Pines, Grapes, Lichee, Star-apple (Chrysophyllum Cainito), Monstera deliciosa, Persimmons, Sapadilla-Plum, Guavas of several sorts, Eugenias, Passion-fruits (Passiflora edulis), and P. quadrangularis, the Granadilla; Oranges, Lemons, Tamarinds, Peaches, &c. The varieties of Peaches are all seedlings, and bear abundantly, but they are of poor quality. The fruits are ripe now (December), but none of the English Peaches will succeed. I have had them for six years, and have not seen a flower on either Royal George or Noblesse; indeed, they are dying out. The seedling Peaches bear the second year from seed. Grapes last about three months, but we have Pines nearly all the year round, and one gets tired of them. The Mangos and Grapes are just ripening. Melons we eat at breakfast. It is rather hot for them just now, but towards the end of January and in February, when the temperature is a little cooler, they succeed better. It is not the shade-heat that injures them, but the intense direct sunshine, which often reaches 176°. In the shade we seldom exceed 95° at this place, but a few miles inland it reaches 109°. This (the State) nursery was established for the purpose of introducing fruits, plants, drugs, fibres, and other things, of commercial interest. But Sugar-cane is the one crop grown by the farmers, and great attention has been given by the department to the introduction of new varieties from all tropical countries, but New Guinea has given us the greatest number. I have been working up the Coffee industry, and have succeeded in getting many of the farmers to make a beginning. The Coffee succeeds well here, and will pay better than Cane. Our available flowers are mostly tropical species. Amaryllids are grand. Our bedding-plants are a few Coxcombs, Balsams, &c.; but Verbenas, Phlox Drummondi, and Zinnias, also do well. None of the beautiful spring-flowers, such as Crocus, Tulips, Agapanthus, Polyanthus, Auriculas, Narcissus, &c., will live. Pears, Apples, Gooseberries, Currants, Strawberries, Raspberries, nor English Plums, will grow. Such plants as Bougainvilleas and Tecoma venusta are gorgeous. Poincianas, especially P. regia, are very beautiful. The colours of all these and many others are much more intense than you know them. Tecoma, or Bougainvillea, when they have entirely enveloped a house, are a grand sight; but still, the variety of the old country compensates for the few gorgeous things we have. The Orchids are poor; Dendrobium bigibbum is the best epiphyte, Phaius longifolius the best terrestrial; Dendrobium Hilli and a large buff variety are very good. This would be a beautiful country if its rainfall was better distributed. In the wet season I have known 17 inches of rain fall in twelve hours. I am sending you a photo of my house at the end of winter. The big plant on the porch is Beaumontia, but it is nearly out of flower. Allamanda Hendersoni covers all the west side; it flowers all the year round. *D. Buchanan, State Nursery, Mackay, Queensland.*

Botanic Garden of the Straits Settlements.

We have received the *Agricultural Bulletin of the Malay Peninsula* for December, 1898, and among its contents note articles on vegetables, poisonous plants of the Malay Peninsula, and Sugar-cane from seeds in the Straits Settlements; the latter subject illustrated with an excellent plate, showing the development of the young canes when twenty-four, thirty-eight, sixty-two, and eighty-three days old respectively. Further papers deal with shade trees, para-rubber, lemon-grass oil, citronella oil, Coffea stenophylla, and Coffee-blights, fungoid and insects.

As a mixture for destroying scale-insects, the following is recommended by Sir W. T. Thiselton Dyer:—"Heat milk nearly to boiling-point, and mix with double the quantity of kerosene; stir briskly until a thick creamy liquid is obtained. Dilute with ten times the quantity of water. Spray or apply with a brush, keeping the mixture constantly stirred. Sour milk is as efficient as fresh. If milk cannot be obtained, or if the mixture is required in large quantity, a strong soap-emulsion may be used in its place."

Agriculture and Forestry of New South Wales.

The Report, up to December 31, 1897, of the above-mentioned Department is now before us, and the Under-Secretary in presenting it, says that:—"The efforts of the Department to advance the agricultural interests have met with a full measure of success, and at no time in the history of the colony have the prospects of the industries allied to agriculture been so promising. Despite the fact that the two seasons covered by the period of this report were among the most disastrous ever experienced in the colony, the output of farm and orchard products has been unprecedented; and this pleasing circumstance can, I think, be logically regarded as a result of the adoption of better and more effective methods promulgated by the Department, which place the producer at more advantage in combating adversity of season."

"Queensland Agricultural Journal."

The January number of this publication contains papers on the Queensland Agricultural College, Tobacco, Cultivation of Chilies, Fruit Culture and Viticulture. Grafting fruit-trees is dealt with, and illustrated by plates showing the various processes. In the botanical section of the journal, Mr. F. M. Bailey mentions and illustrates the "Hedge Nettle," Stachys arvensis, as a plant poisonous to stock. There is also a paper on plant-helping insects, accompanied by a plate of Cirrhopetalum robustum, copied from the *Botanical Magazine*; notes on forestry, and on general subjects.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

The Earliest Celery.—As soon as the plants raised from the first sown seeds are large enough to be handled, let them be pricked off either into well prepared boxes or on to a gentle hot-bed. If on to a bed let the soil be rich, and it should be raised to within eight inches of the glass, which should be kept clean so as to admit the light. Before the seedlings are put out, the soil must be patted with a bright spade so as to make it firm and smooth, and when planting make the holes deep enough to let the young roots drop in easily down to the seed-leaf, taking care not to bruise them when filling in with the dibber. Slightly shade the plants in sunny weather, afford moisture to the soil; and keep the lights closed for a few days, when less and less shading may be applied, and air given gradually. If soot be dusted lightly over the plants, slugs will do no harm to them. The temperature ought not to be lower than 55°. Plants pricked off into boxes should be kept in a light position and as near the glass as possible; a peach-house or vinery newly started will suit them admirably. For the main crop a sowing of varieties may be made in boxes, seed-pans, or under hand-lights, using fine rich soil. If boxes or pans are used, glass or slates should be placed over them till germination takes place. But little warmth beyond that of the sun will be necessary. The plants may be pricked off into cold frames, or on to a warm border, special provision being taken to ensure quick yet stocky growth.

French Beans.—Plants in bearing should have the usable pods gathered as soon as they are fit for use, and if not required for immediate consumption they may be tied in small bundles, with the stalks arranged at one end, and stood on end in a saucer of water in a frost-proof room. Canadian Wonder and Pale Dun are varieties much liked, but they need larger pots than the early forcing varieties. Use ten-inch pots, and do not more than half-fill them when sowing the seeds. After this date, less drainage of crocks and more fibry loam at the bottom may be used. Sow six to eight beans in a pot, and keep in a temperature of 65°. Great care must be taken to cover up the frames at night, and to admit air, &c. In the open the work will almost be at a standstill; but if not done, make the best use of frosty mornings in getting vacant plots manured, Pea-sticks and Bean-stakes pointed, &c.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Bedding.—Verbenas which have been raised from seed, and Fuchsias, Coleus, &c., from cuttings, should be potted singly in large thumbs, 2½ inches wide by 4 inches deep, if such are in stock, as they take up less room. As soil for potting, that from the potting-bench, if the rubbish be sifted out of it, will do well for this purpose. The leading shoots need not be stopped till fresh roots have formed. It is well to dust over the leaves with

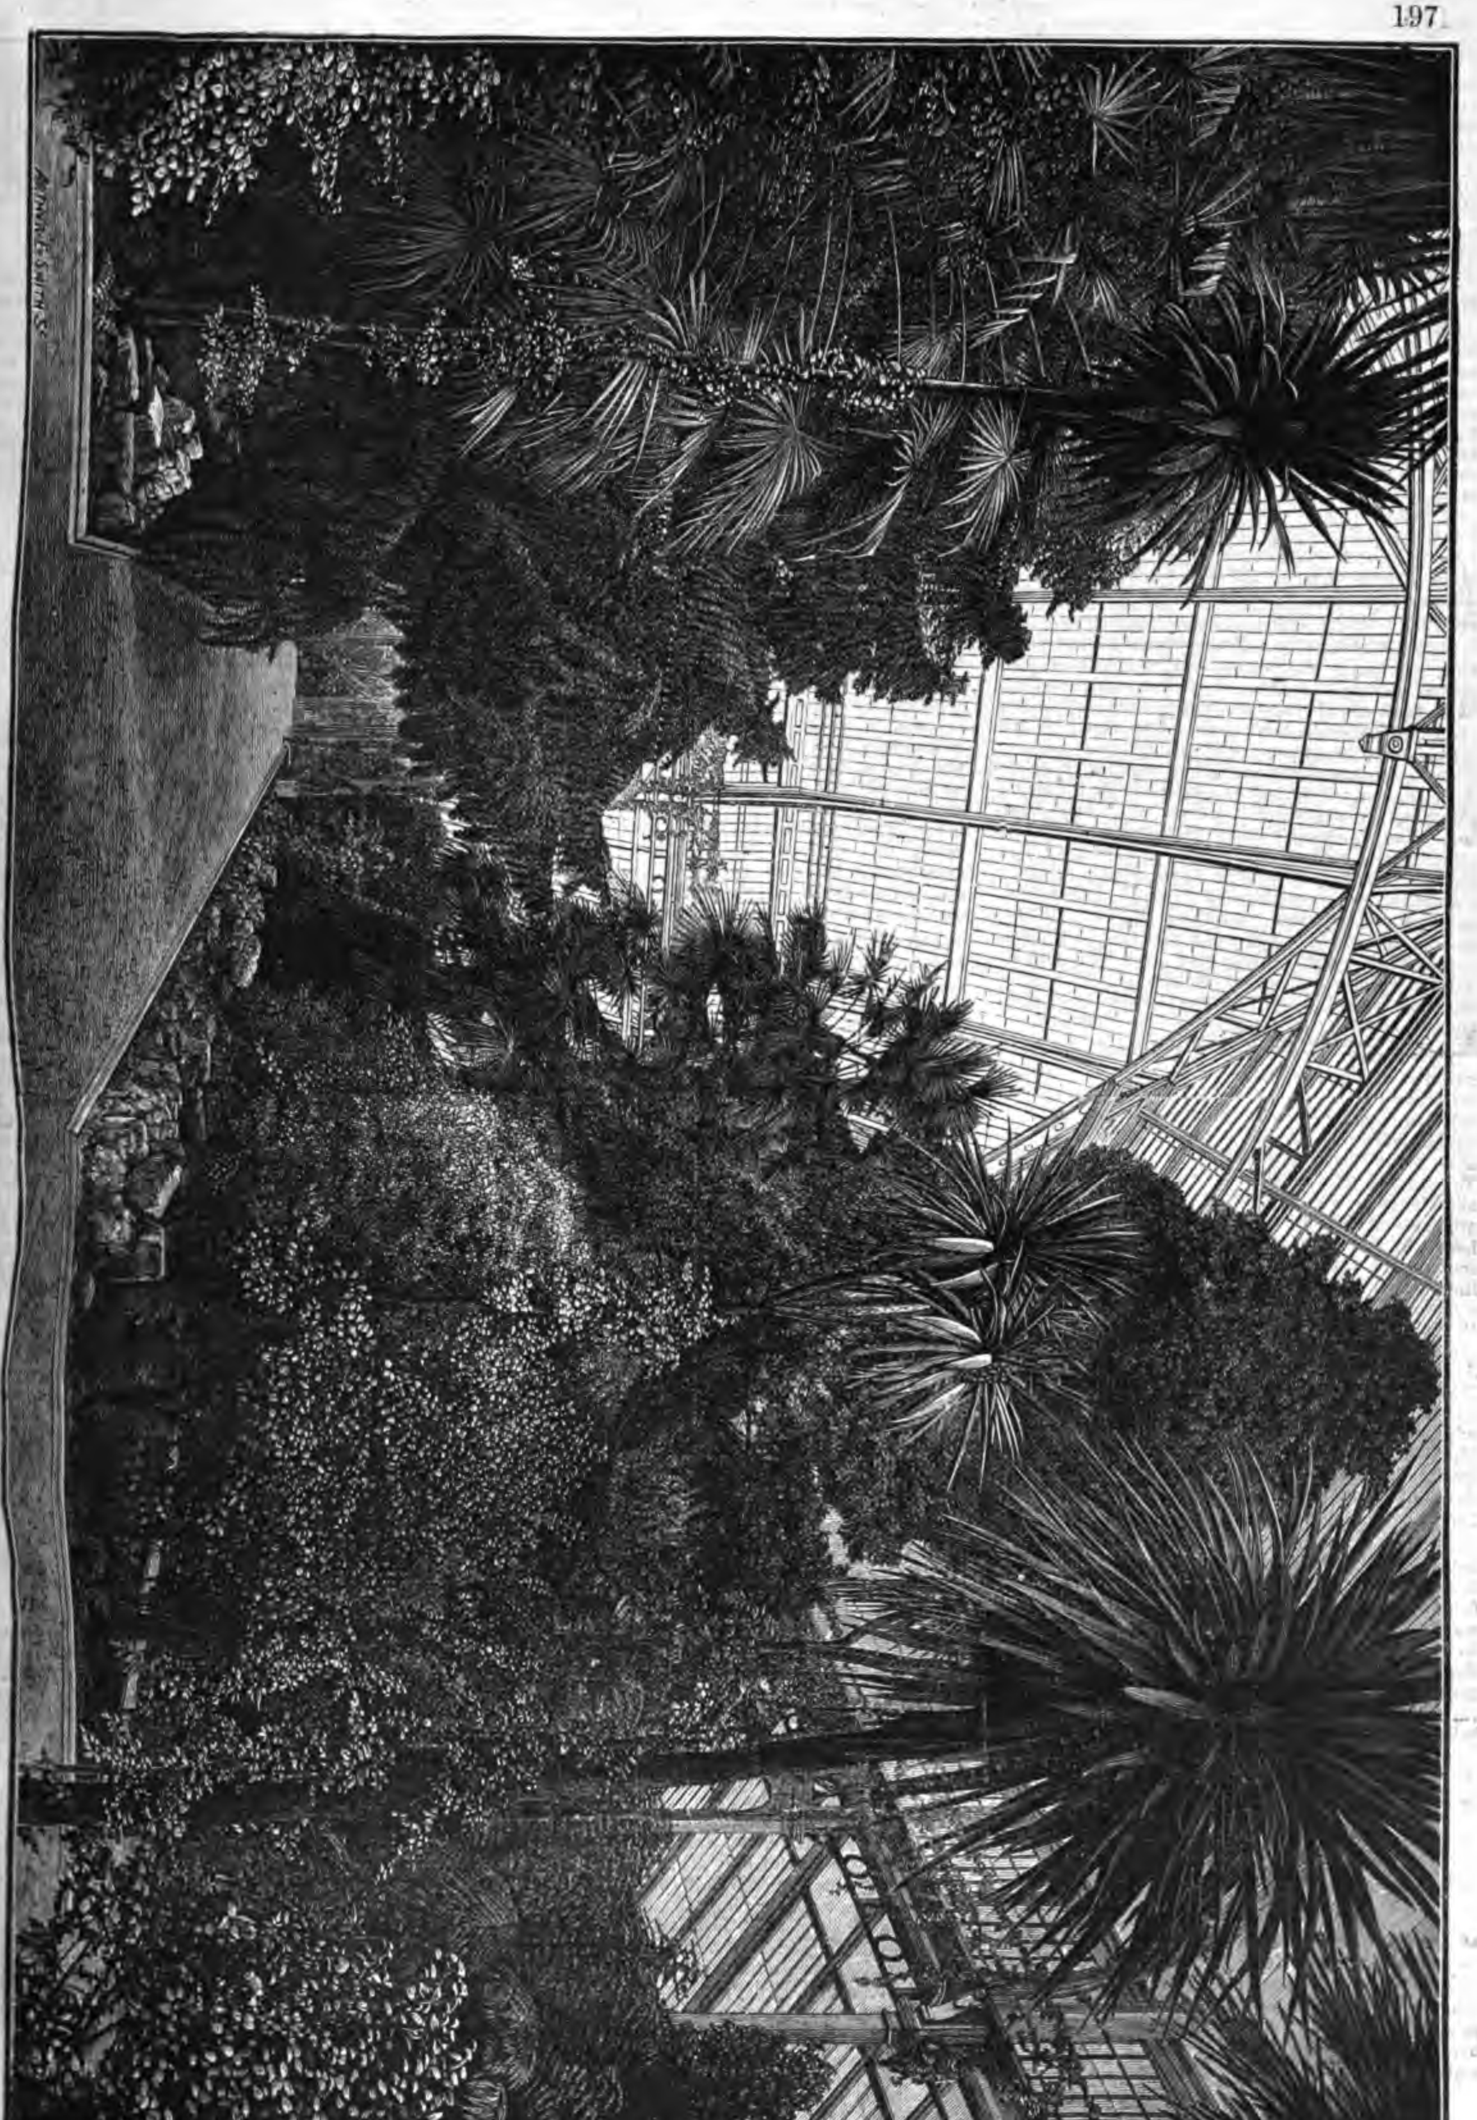

FIG. 74.—INTERIOR OF THE TEMPERATE HOUSE, ROYAL GARDENS, KEW. (SEE P. 195.)

flowers-of-sulphur, in order to prevent mildew, and fumigate lightly to destroy aphides, usually making its appearance at this stage. Seedling plants of Ricinus, Solanums, and other subtropical plants, should be shifted into larger pots, and kept growing by syringing the plants occasionally, and shading from the sun. A maximum temperature of 70° will be sufficiently high for them. The last cuttings of Iresine, Coleus, and other bedding plants, should now be taken, as after this date they rarely make good plants by bedding-out time.

Chrysanthemum maximum.—The newer and dwarfer varieties are the most suitable to plant out. This species of Chrysanthemum is easy of cultivation on a loamy soil, an occasional application of liquid-manure being all that they need. C. m. Duchess of Abercorn is a very dwarf habited variety, possessing pure white flowers of much substance; Elaine has handsome, large pure white flowers; C. m. G. H. Sage is the prettiest, having frilled petals; C. m. fimbriatum has thread-like petals; C. m. Maurice Prichard is a snowy white very fine flower; C. m. Mrs. Head gives flowers of great substance, and 4 inches in diameter; C. m. grandiflorum is a usually fine and late-flowering variety.

Potentillas (double).—These plants possess beautiful flowers of the richest shades of colour that appear during the summer and autumn months. The plants are of compact neat growth. A loamy retentive soil suits them best. The finest of the self-coloured varieties are P. californica, yellow; Drapeau, crimson-maroon; Etna, scarlet; Hamlet, dark crimson; Nigra plena, dark purple; Velours Pourpre, velvety purple; Vulcan, rich deep crimson. The varieties having parti-coloured flowers are Chinois, large rich maroon and yellow; Feu Follett, orange scarlet, with broad orange margin; Golconda, rich crimson, edged gold; Dr. André, gold yellow, suffused vermilion; Milton, yellow, heavily blotched bright red; Madame Rouillard, rich velvety scarlet, edged gold, very fine; and Le Vésuve, bright red, edged yellow. If set out at the beginning of April the plants make good-sized clumps, and they flower profusely the first year.

Pyrethrums, Double and Single-flowered.—Both varieties are very effective border plants, excellent for affording flowers for cutting. The plants generally are easily raised from seed, but selected named varieties are so cheap that it is preferable to purchase plants than to rely upon seed. To produce fine flowers, very rich soil, and an abundance of water when growing and flowering, are necessary. Slugs and snails devour the young leaves at the commencement of growth: a ring of soot should, therefore, be placed round each plant; lime is also useful as a deterrent. After flowering, a mulch of rotten manure over the roots is beneficial. P. Aphrodite, Penelope, Princesse de Metternich, are fine double whites; Solfaterre and Toison d'Or, double yellows; Alfred Kelway, Beauty of Laeken, Meteor, and King Oscar, deep crimsons. The best single varieties are Empress of India, Magnet, whites; James Kelway, Mrs. Bateman Brown, Sherlock, crimsons; Jubilee, Tasso, and Orlando, scarlets. It is best to plant the self colours, as the flowers pale out after flowering a few days to other tints.

Helianthus.—These perennial Sunflowers soon exhaust the soil, and require annual transplantation to produce fine flowers. The plants should be fully exposed to the sun, and the soil should be well manured and dug. In transplanting, let the plants be divided into clumps of six stems each, and plant them 3 inches below the soil. H. decapetalus major, H. maximus, and Soleil d'Or, are good varieties. H. rigidus, known in gardens as Harpalium rigidum, form a noble clump. H. doronicoides and lætifolius should be planted where the underground roots and suckers cannot ramble to the injury of other plants.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Tuberous Begonias.—If seed was sown as advised at the end of January, the seedlings will now require to be pricked out an inch apart into pans or small boxes, filled with a compost consisting of two parts loam, one part leaf-soil, with plenty of sand. After the strongest of the seedlings have been carefully lifted and pricked out, level the soil among the smaller ones, and afford a watering if necessary, to settle the soil about them, and in the course of ten days or so these may also be pricked out.

Kalosanthes coccinea, delicatissima, &c.—Plants which are showing signs of flowering may be assisted with occasional applications of weak liquid-manure. They should be afforded a position near the glass, and be occasionally turned round, to prevent their becoming drawn in one direction. Kalosanthes need comparatively small pots and a porous compost, composed of three parts loam, one part peat, and a liberal addition of broken brick-rubble, crocks or charcoal, and sand. They should be grown in the greenhouse during the winter, and until the flowering is past. In the summer they may be placed in a cold frame or in the open air.

Primulas and Cinerarias.—A small sowing of seed of the Chinese Primula and Cineraria may now be made for early flowering. The seed should be sown thinly in well-drained pots or pans, which have been previously filled with finely-sifted soil, and well watered. The Primula seed should be only slightly covered with fine sand, and that of the Cineraria may have a sufficient quantity of the compost sifted over it through a fine sieve to cover it. The pans should then be covered with a sheet of glass, and be placed in an intermediate temperature, or on a mild hotbed, or under a handlight in the greenhouse, shading carefully, or, preferably, affording the pans a position where they will not be exposed to direct sunshine. Primula obconica, P. verticillata, and P. floribunda may also be sown in quantity at this time, under the same conditions as the Chinese Primula. Great care should be exercised in affording water to Primulas, both before germination and while the seedlings are small, the roothold during the early stages of germination being so extremely precarious that a pan of seedlings might easily be ruined by one careless watering with too coarse a rose.

Flowering Shrubs in Pots.—Steps should always be taken to afford some kind of protection to shrubs which have been forced, and have done duty in the conservatory, if it is intended to use them for the same purpose another year. Sometimes it is possible to set apart an old house or deep pit for this purpose; but failing this, a rough framework might be constructed in a sheltered corner, the sides being matted, and the top covered with hexagon netting, or similar material, adding some mats during severe weather. The plants should be stood closely together under this protection, where they will gradually become hardened, and may then be plunged in the reserve ground. The above remarks refer to such plants as Ghent Azaleas, Spiræa confusa, double-flowered Cherry, Staphylea colchica, Lilacs, Hydrangea paniculata, and Rhododendrons. Deutzia gracilis should be cut back hard immediately after flowering, preserving any young growths which may have started from the base of the plant, and the plants placed in a house or pit where a gentle warmth is maintained, and every means adopted to induce them to make a strong growth. Liquid-manure should be afforded, the object being to produce as many strong shoots as possible from the base of the plant, and thoroughly ripen these by plunging the plants in the open air when the growth is completed. Where these and other flowering shrubs were potted in the autumn, as is usually the practice, no further potting should be needed at this season.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Zygopetalum Perrinoudi.—Our plants are pushing up their flower-spikes, and being rapid in development, they will have passed out of bloom before the plants stand in need of any top-dressing or repotting, that is, when the roots appear at the base. As soon as these are noticed, the work must at once be attended to. Zygopetalums like plenty of drainage materials, and some of the crocks may be inserted round the ball after it is in position. Loam, peat, and sphagnum-moss, in about equal parts, form a suitable compost. Place the plants in a warm shady part of the Cattleya-house; afford water sparingly till it seems they are re-established, and when the pseudo-bulbs cease to grow, keep the materials moderately dry, but do not cause them to shrivel.

Z. Mackayi and its varieties, and Z. maxillare, may often be seen in luxuriant growth in establishments where Orchids have no special treatment, but in collections of Orchids they are rarely seen in a healthy condition, though why this should be it is hard to understand. Very few Zygopetalums like disturbance at the root, hence repotting should be done but seldom. Thrips also cause ill-health and disfigurement, the nature of the young growths rendering it difficult to get at them without injuring the leaves in the process. Z. Mackayi and its varieties crinitum and intermedium, with Z. brachypetalum, can easily be grown in well-drained pots in equal portions of loam, peat, and sphagnum-moss, a good sized piece of crock or nodule of charcoal being placed here and there to keep the compost open. The temperature and other conditions of the Cattleya-house suit these plants best. Z. maxillare may be fixed to a piece of tree Fern-stem whose base is fixed in a flower-pot for convenience of staging. It requires a similar temperature but denser shade. My remarks apply equally to Z. rostratum, excepting that this species needs more warmth. As has been said, water must be very sparingly afforded after disturbance, except in the case of the last two, only affording it in quantity when the plants are re-established. Never let water lodge in the folded leaves.

Promenæa citrina, stapelioides, and xanthina, now included under Zygopetalum, grow well when planted in small hanging pans in the Masdevallia-house, and in the usual Orchid-compost.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

Raising Seedling Apples and Pears.—Those who wish to raise new varieties should sow the pips at this season. The plants, if not fit for anything else, will provide stocks for grafting or budding. If merely stocks are to be raised, a border with a west aspect should be prepared preferably, and the surface brought into a fine condition; then shallow drills may be drawn ½ inch in depth and 6 inches asunder, in which the pips should be scattered thinly, and be covered with the finer particles of the soil. The plants will be large enough for transplanting in the autumn in lines, about 8 inches asunder, and 4 inches apart in the rows. The tap-root should be cut back when transplanting, to induce branching of the roots. If only a few seeds are to be sown, which is usually the case in private establishments, sow them in boxes or pots, and stand these in a cold frame or pit, and grow the young plants in pots or boxes for a time. To raise a few seedlings in this way gives but little trouble, and there is considerable interest in watching their progress, and should they turn out to be no improvement on existing varieties, the labour expended has not been great; while, on the other hand, the chances of a superior variety being forthcoming, the labour may prove to be well repaid. The pips from any desirable specimen Apple that may show a slight variation or improvement on the type may be selected. Last year I noticed among our Cox's Orange Pippins one fruit more oval in shape than others, and this fruit kept firmer into the spring months. The pips from this one were sown, but whether the seedlings differ from the parent in keeping or other qualities, has yet to be proved. There appears to be more need for a late-keeping dessert Apple of good quality than for early or mid-season varieties, while cooking varieties are already much too numerous. Pears may be raised similarly.

Transplanting Young Currant and Gooseberry Bushes.—Any that are still in the cutting-bed should now be removed to fill up vacancies, or planted out in nursery rows at 18 inches apart. Before planting, let the longer roots be shortened, also all stem-roots, and any buds on the stems likely to form shoots under-ground, or nearer to the surface of the soil than 9 inches.

The Black Currant-bud Mite.—Every Black Currant bush should be carefully examined, and if there are swollen buds, remove the shoots affected, and burn them forthwith. One of the best means of prevention is said to be strong growth, and to this end weakly bushes should be cut hard back, and top-dressed with rich decayed manure, wood-ashes, and fresh loamy soil in about equal parts. In forming new plantations, the rows should be at wide distances apart, thus leaving space for some other crop to be grown between, which assists in checking the ready spreading of the mite from row to row.

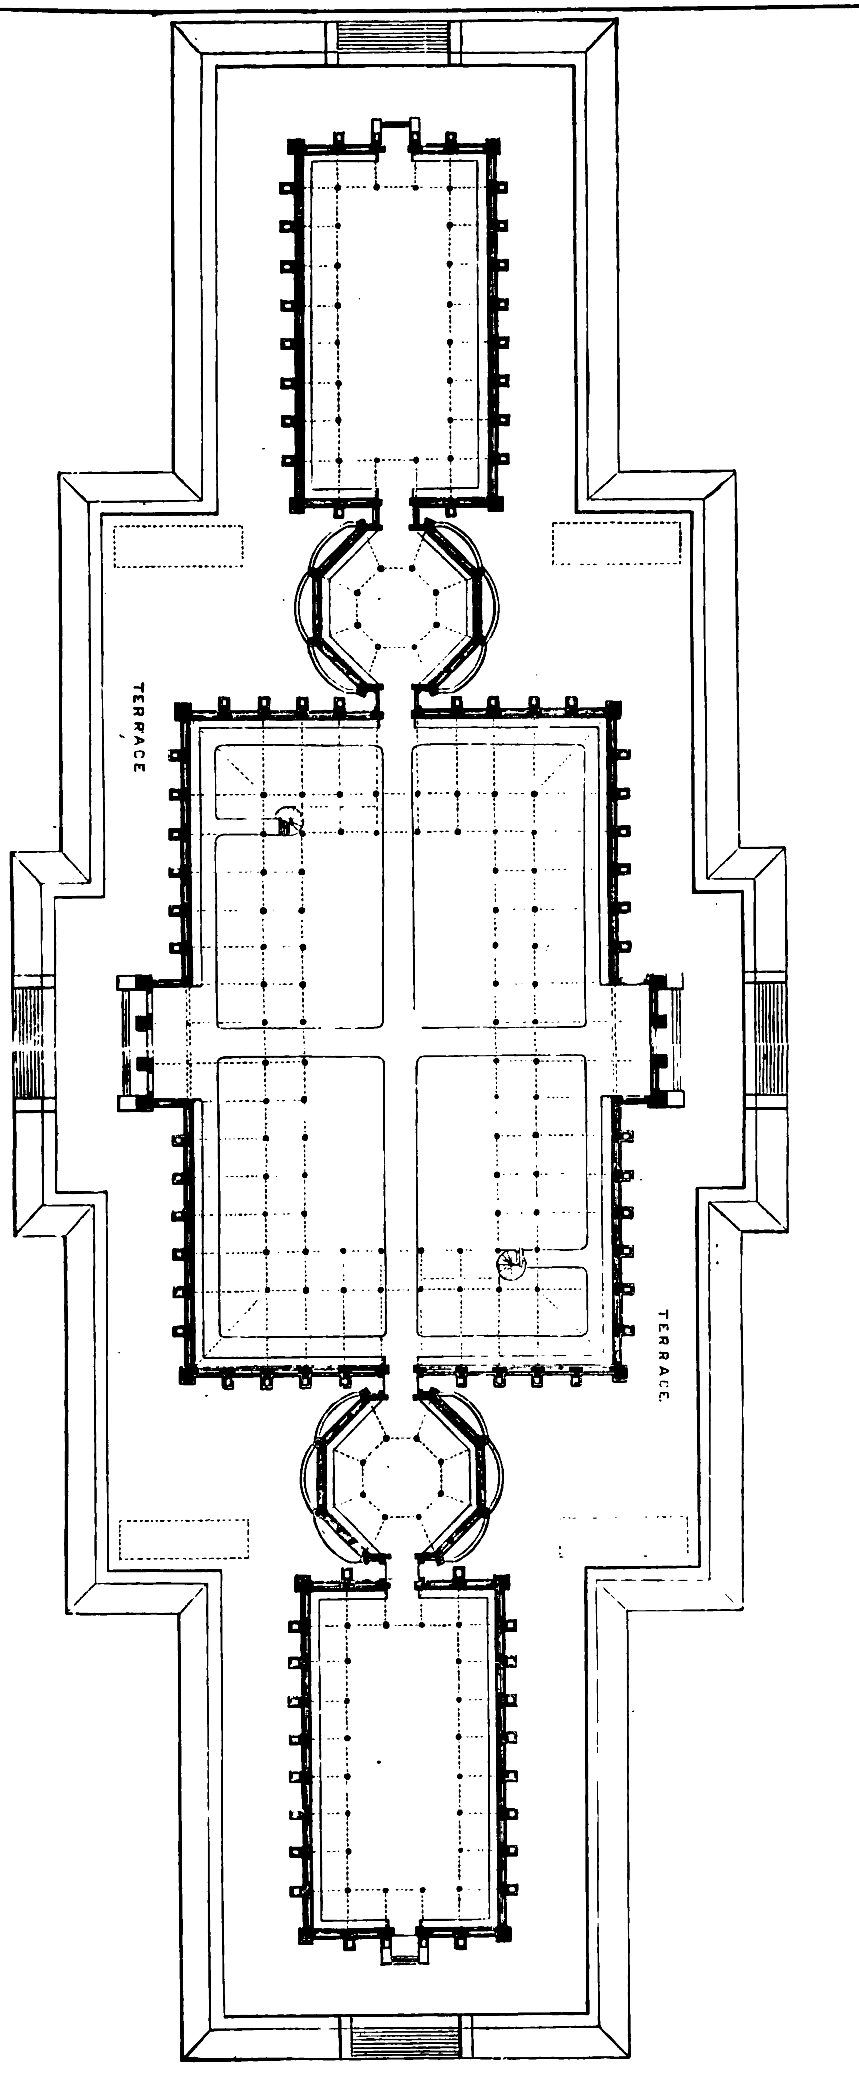

Fig. 75.—Ground plan of the temperate-house, Kew, as now completed. (See p. 193.)

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long
Rood Ashton, Trowbridge.

The Early Peach-house.—The earliest varieties in this house, if started early, December last, are probably stoning, and for a time no apparent progress will be made. If there is any doubt about a sufficiency of lime being present in the soil, it will be well to apply some at once in a slaked state to the border, and wash it down to the roots immediately it is spread over the surface. Lime is a very necessary agent in the growth of all stone fruits, and if applied in small quantities no harm can be done. The heavy strain imposed on the trees that are carrying full crops of fruit will render necessary the application of a fair amount of moisture to the whole depth of the border; and in the case of old trees, occasional application of liquid manure from the stable and cow-yard, diluted to a safe strength, will be helpful. Artificial manures answer a similar purpose, but unless something of a soluble nature be given, the trees will not derive an immediate benefit. The trees are better sustained if both natural and artificial manures are given. The growth of the trees will now be rapid, and the shoots must be tied neatly to the trellis, but retaining only sufficient to furnish the tree without crowding. When the stoning period has passed, the fruits will swell rapidly, and the better they are then exposed to sunshine the better. Where it happens that the foliage cannot be tucked in behind the trellis wires or branches, pinch off any leaves that directly overhang the fruit.

In the Orchard-house.—Peaches and Nectarines will now be in full bloom, and will need abundant ventilation in suitable weather to assist pollination of the flowers. In cool houses there is usually little difficulty in obtaining a good set; a sharp rap from the hand on each tree stem at noon dispersing a sufficiency of pollen grains. The same remarks apply also to Plums, Pears, and Cherries while in flower, but it is a safer practice to lightly brush the open flowers daily with a rabbit's tail, camel's hair brush or Pampas-plume. Where there are the means for supplying it, fire heat may be advantageously given during the flowering period, but only sufficient to dispel damp and frosty air. The severe weather of the past week or two has proved a serious trouble to the open flowers in unheated houses, and in very many instances light rather than full crops are inevitable. Trees in pots and borders in unheated houses have been kept on the dry side at the roots, so as to lessen the risks from frost, but sufficient water should now be given to moisten the soil to the depth of the border. Clear water is sufficient at the present stage. The orchard-house will conveniently accommodate a batch of Strawberries for supplying fruit just previous to the ripening of the earliest outdoor fruits. If they are put upon shelves, these may be lined with freshly-cut turf placed grass side downward. In this the roots will enter through the drainage hole, and find moisture and support when the sun has much influence. Wood moss may be employed instead of turf if this can be easily obtained in quantity, but unless the shelves have side strips this would dry quickly. From freshly-cut turf there arises just sufficient fresh grass to protect the pots from undue exposure to the sun.

VARIORUM.

Rhus toxicodendron: Poison-Ivy, and its Antidote. — According to Dr. Pfaff, of the Harvard Medical School, the poison of this plant, which in some persons causes intense irritation of the skin when communicated by touching the leaves, is a non-volatile oil, insoluble in water, and therefore not easily removed from the skin by washing. The oil is soluble in alcohol, and is made innocuous by sugar-of-lead. It will be seen by this that timely washing of the irritated parts with alcohol will serve to prevent injurious effects. Sugar-of-lead mixed with alcohol till the mixture obtains a milky appearance, is recommended in cases where irritation has become very great from delay to apply the remedy. It should be remembered that sugar-of-lead is a poison, and the solution must therefore only be applied externally. "*American Gardening.*" [The old remedy, "Goulard Water," which is an acetate of lead, answers the purpose very well. Ed.]

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. Provinces.—*March* 28 (6 p.m.): **Max. 55°,** Ipswich; **Min. 45°,** Shetland.

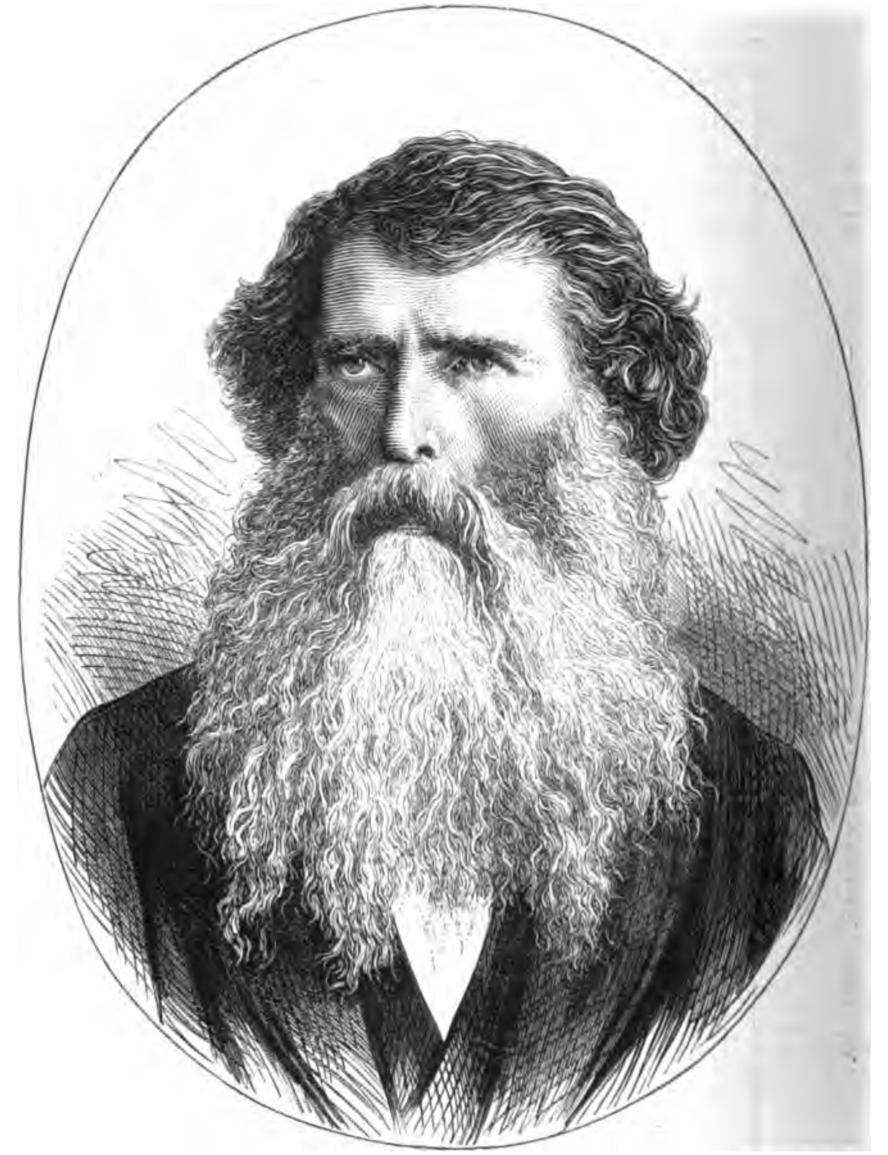
Charles Naudin. We are pained to have to announce the death of one of the most distinguished gardener-botanists of our times. Charles Naudin, the Director of the Experimental Garden at the Villa Thuret at Antibes, died suddenly on the 19th ult., in his eighty-fourth year. To the rank-and-file of gardeners his name will probably not be familiar, but those concerned with the problems of systematic botany, hybridisation, experimental cultivation, and the acclimatisation and distribution of economic plants, will recognise that a mighty leader has fallen. Naudin was born at Autun in 1815, and has been an occasional correspondent of this Journal almost from the beginning. The friend of Lindley, he extended his countenance and co-operation to the present Editor also.

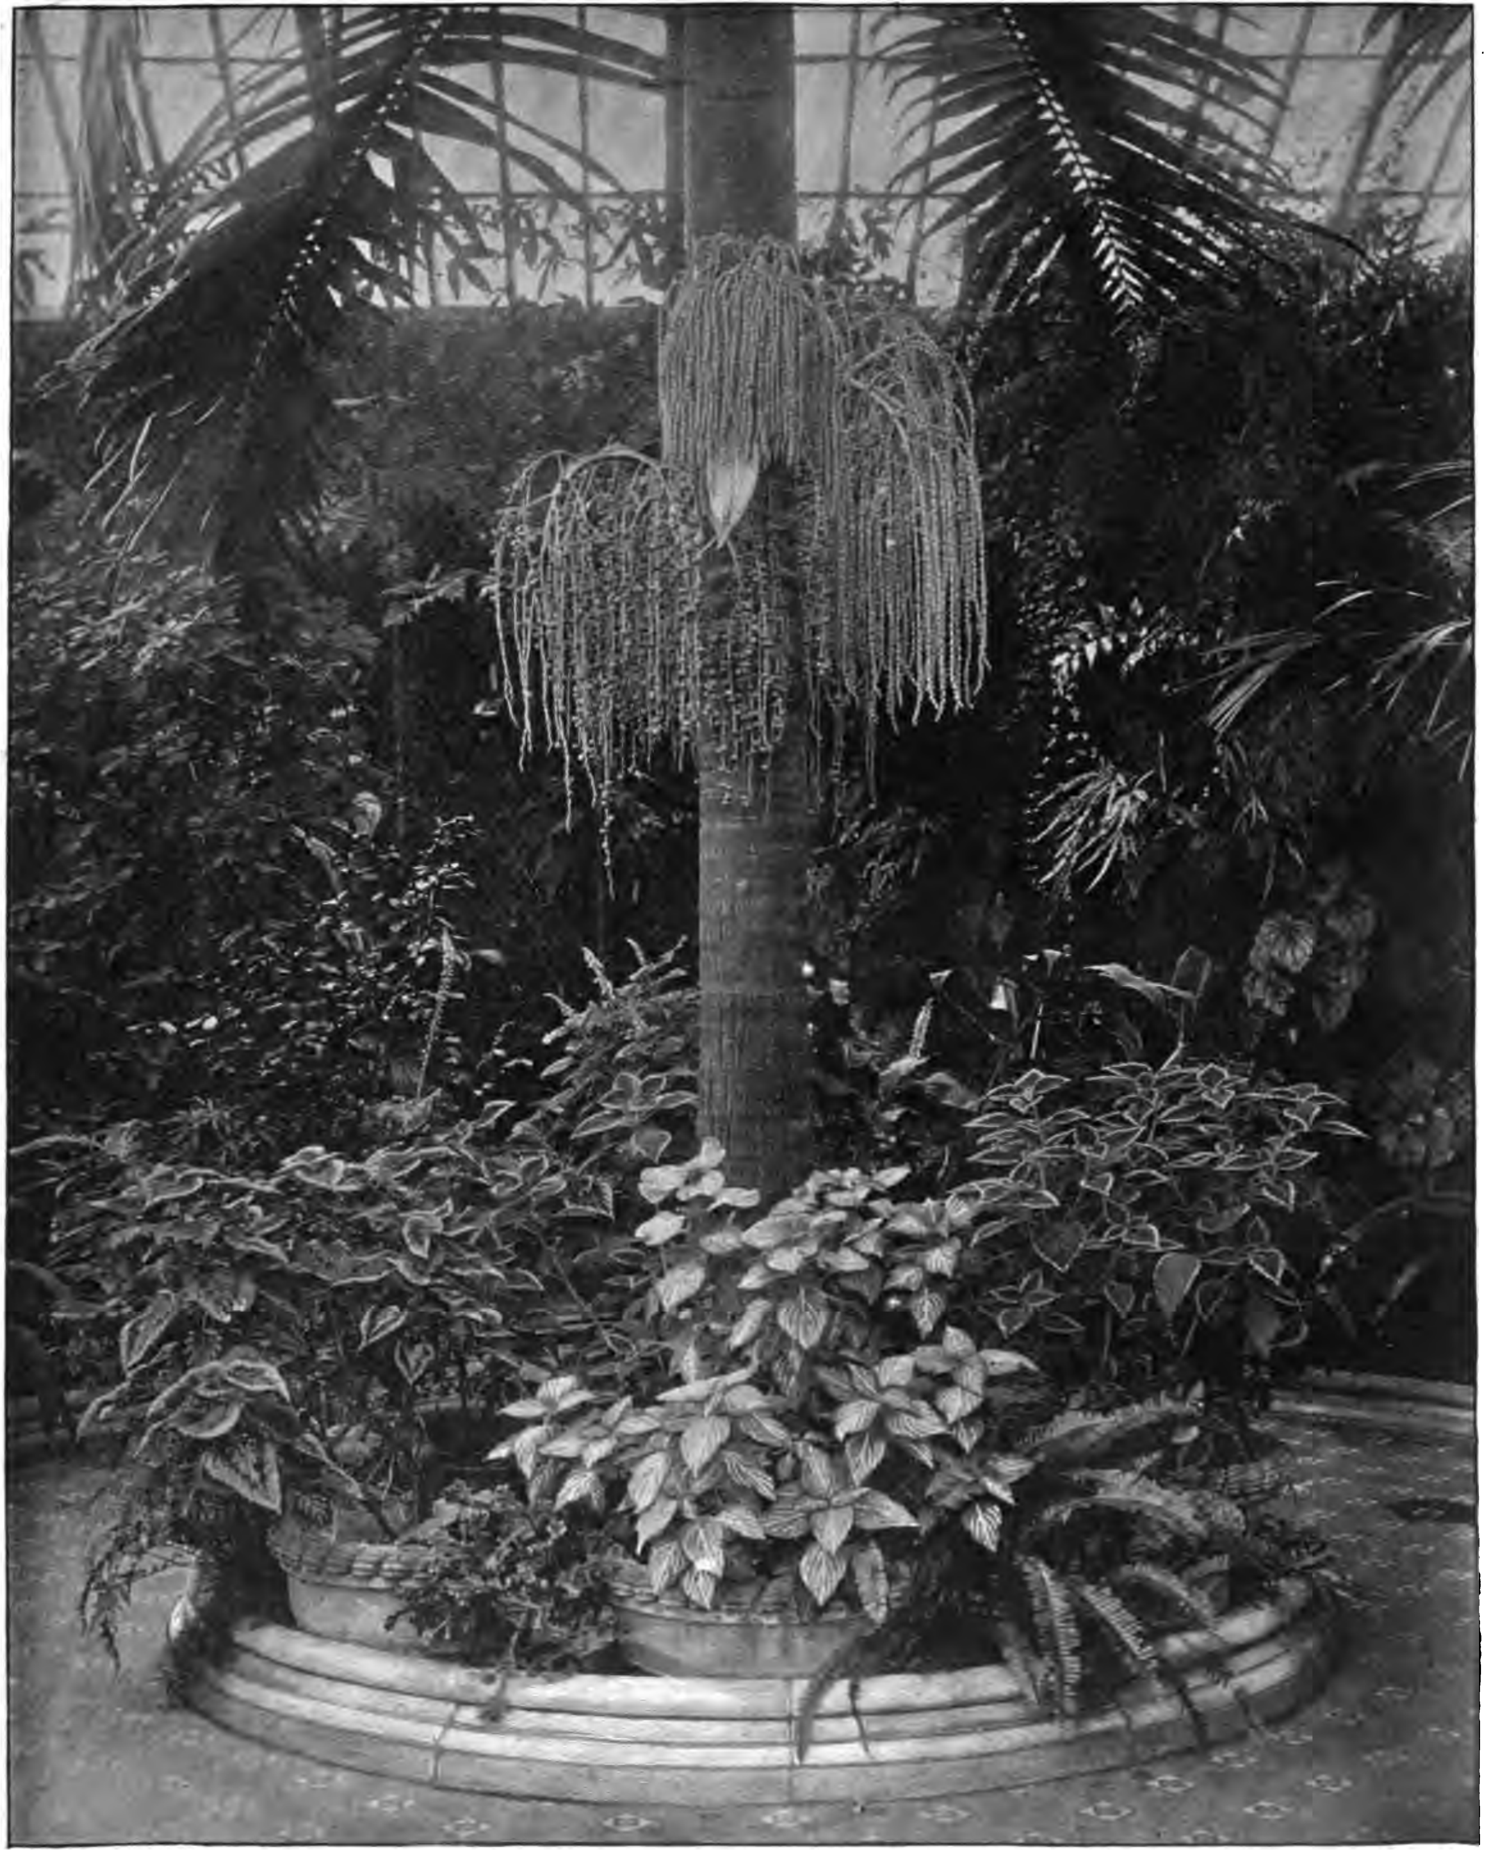


THE LATE CHARLES NAUDIN.

Records are not at hand, but relying on memory, we may allude to some of the principal features in his career. At the time of our first knowledge of the deceased naturalist, he was in the service of the "Museum" at Paris, the associate of Brongniart, and especially of Decaisne at the Jardin des Plantes. Here he carried on those remarkable experiments on hybridisation which will secure for him a permanent place in the history of botany. Here he studied with such minute care and accuracy the difficult order of Cucurbitaceæ, availing himself largely of the resources afforded by the garden, and by no means exclusively relying on the study of herbarium specimens.

For several years M. Naudin cultivated and made experiments on some 1200 of these plants belonging to various species and varieties, which by his observations and experiments, he was enabled to range under three species, each presenting very numerous and often analogous variations. The description and classification of the endless series of Gourds, Cucumbers, and Melons, are extremely remarkable, and valuable for cultural purposes, were it only for the practical hint obtained, that in the case of such plants as the Melon and Cucumber, it is better and more profitable to endeavour to improve existing kinds, than to introduce new kinds from other countries.

Here, too, he elaborated the Melastomaceæ, and contributed to the famous *Bon Jardinier*



THE PALM CONSERVATORY AT MALVERN HOUSE, THE RESIDENCE OF J. BURTON, ESQ., MAPPERLEY, NOTTINGHAM.

and the *Revue Horticole*, and here he produced, in conjunction with his friend Decaisne, one of the most useful horticultural treatises that exists, the *Manuel de l'Amateur des Jardins, Traité Général d'Horticulture*, a portion of which was translated and adapted to English requirements by Mr. Hemsley in 1873.*

After leaving the Jardin des Plantes, Naudin established himself at Collioure, in the Eastern Pyrenees. In the genial climate of this spot he was enabled to pursue his experimental researches, and his efforts to acclimatise and distribute to suitable localities plants of economic importance or ornamental character.

After the death of Thuret, the Villa Thuret was presented by his representatives to the French nation. Thuret, it may be remarked, was not only a genial and sympathetic student, and a most distinguished algologist, but he had, in conjunction with his friend Bornet, established a garden richly stocked with rare and interesting plants, and wherein the two botanists pursued their experiments in the hybridisation of Cistuses and other plants. When this little paradise became by gift the property of the nation, it was worked as an adjunct to the Paris garden, and if all Europe had been searched, no more competent a director than Naudin could have been found for it. He threw himself into the work with energy and zeal. The extension of the French colonial possessions in Algeria and Tunisia afforded him the opportunity of contributing to the development of their resources by the introduction of Eucalypts and other plants of economic importance. In this part of his work Naudin was helped by his ever zealous friend, Von Mueller, and the *Manuel de l'Acclimateur* of the French botanist, a most useful publication, is avowedly based on the "Select Extra-Tropical Plants" of his Australian collaborator.

Deafness and occasional severe attacks of neuralgia and sciatica prevented Naudin of later years from mixing much in the world of horticulture or botany. His letters, however, were always fresh and full of information, with many a classical or biblical quotation. He did not content himself with the Greek of the schools, but sometimes confounded his correspondents with a phrase or two of modern Greek. Naudin's merits were recognised by his own and by foreign governments; and what must have given him even greater satisfaction, was the knowledge of the esteem and veneration in which he was held by his colleagues. Naudin was a foreign member of the Linnean Society, and to him in recognition of his great services to gardening, and especially to hybridisation, a Veitchian Medal was awarded in 1897.

The meeting of the Académie des Sciences on the 20th ult. was suspended by the President, M. van Tieghem, as a sign of mourning for the father (*doyen*) of the Botanical Section.

THE MALVERN HOUSE CONSERVATORY, MAPPERLEY. — Our supplementary illustration shows the conservatory at Malvern House, Mapperley, Nottingham, the residence of J. Burton, Esq. As in many such structures, the chief effects are made to centre round some object prominent for its size, or the form or beauty of its foliage or stem, or of its flowers. In Mr. Burton's conservatory this central object is a Giant Seaforthia elegans, which is rendered especially noticeable by a stone curb surrounding the base, enclosing a space which can be filled with any kinds of decorative plants in season; in this instance, these consist of Coleus and Ferns in variety.

THE PROTECTION OF BIRDS.—The discrimination between birds useful and those that are injurious to gardeners and farmers should, with the increase of literature relating to the subject, become more and more easy. For instance, the Board of Agriculture publishes valuable leaflets describing in brief space the nature and habits of various British birds, and illustrating the different species. We have before us two of these pages: No. 54, the Spotted Flycatcher; and No. 55, the Swallow. Leaflets such as these should be widely spread abroad and studied. Copies of them will be sent free of charge and post-free on (unstamped) application to the Secretary, Board of Agriculture, 4, Whitehall Place, S.W. Further, we note the *Eighth Annual Report of the Society for the Protection of Birds* (for January to December, 1898), including a summary of the Wild Birds Protection Act. Any efforts tending to foster and increase rare and desirable species of birds deserve all encouragement.

DISTINCTIVE CHARACTERISTICS OF THE SEXES OF GINKGO BILOBA.—*The Journal de la Société Nationale d'Horticulture de France* for February contains a note upon the secondary distinctive characteristics of the two sexes of Ginkgo biloba. The species is known to be diœcious. Now with trees that never bear either flowers or fruit it is very difficult to distinguish the male from the female specimens, and this is sometimes of importance. M. L. Henry, head gardener at the Muséum, described in the *Bulletin de l'Association des anciens élèves de l'école d'Horticulture de Versailles* (1898, p. 597), an easy means of recognising the sexes in this particular instance. Many years of careful observation have enabled M. L. Henry to state that in Paris, with the female Ginkgo, the leaves fall three or four weeks later than with the male. Generally, male Ginkgos lose their leaves completely at the end of October, or more frequently at the beginning of November. At this period the female Ginkgos still retain all their leaves, which are all green and only turn yellow and fall at the end of November, or even the beginning of December. Premature frosts may accelerate this fall. But, according to M. L. Henry, there is always a very marked and appreciable difference between the season of the fall of the foliage of the male and of the female plants.

SPITALFIELDS MARKET.—We some time since drew attention to the possibilities attending the scheme to transfer this popular East-end fruit and vegetable market from the freeholder to the County Council; and now we are informed that, subject to parliamentary sanction being obtained, the Public Control Committee of the L.C.C. have arranged for the purchase of the freehold interest of the market, together with the rights attaching thereto, for the sum of £170,000, in addition to a sum of £1,250 for legal charges. The Council intend, when in possession, to make great alterations and improvements, in order that the market may fulfil all modern requirements.

"THE ORCHID HYBRIDS."—We learn that Mr. George Hansen, of Berkeley, California, is engaged in compiling the third supplement to his monograph, *The Orchid Hybrids*. As he finds the material accumulating so fast as to have difficulty in keeping note of all hybrids, he intends to print a new index with the supplement in question. It will be set by linotype; and as he will retain all "slugs" as cast, it will only be necessary to interpolate all additions as presenting themselves for future supplements, and the index will again be up-to-date. As only sufficient copies will be printed to supply all subscribers, no surplus stock will be kept on hand, and a new index will be furnished to every subscriber and purchaser of the additional supplement. How laborious Mr. Hansen's task is, is plain to all who ever attempted to register the thousands of crosses raised. He invites the co-operation of all interested in the work, and accepts gratefully every hint for improvement, correction, or augmentation of his lists. He expresses the desire to receive wider information than the one accompanying the crosses as exhibited. He desires to know the exact dates on which fecundation took place, when the seed was sown, and when the seedling reached the flowering state. Whether such crosses had already been raised at different places is immaterial to him, as he wants to register every source of supply for the hybrids in the different collections. It is saying but little to acknowledge the usefulness of Mr. Hansen's work, and to assist him in rendering his work perfect is but assisting ourselves.

THE MADRAS GOVERNMENT BOTANIST. — The Secretary of State has appointed Mr. C. A. Barber as Government Botanist in this Presidency. His duties, as defined by the Local Government in the order communicating his appointment, consist mainly in the prosecution of the systematic botanical survey of the Presidency. He will be also the constituted adviser of Government in regard to all questions and inquiries in economic botany that may be referred to him. The botanist is expected to work in the field for about eight months in the year. For working up the collections made in the field, the botanist will enjoy a recess of three or four months at Ootacamund, which will be considered his official headquarters. The herbarium, being a necessary adjunct to his work, and the more important books which formed the official botanical library of the late Mr. Lawson, will be transferred to the Government Botanist. *Madras Mail*. [In this connection we have only to remark that if the services of Mr. Barber are to be utilised in a manner that will render his appointment of some practical utility to the public, he should be hampered as little as possible with red-tape. Mr. Lawson was one of the ablest botanists that the Madras Government ever had, but his life, we believe, was not worth living owing to the way in which he was worried by the Board of Revenue Orders and Resolutions. Ed. *Indian Gardening.*]

GRAPE FRUIT.—In *Meehans' Monthly* for the present month is a representation of the Pomelo (Citrus), showing the flowers growing in clusters, and weighing down the branches with their weight. It is probably this clustered habit that has caused the fruit to be called "Grape fruit." The flavour of the fruit, we are told, is very different from that either of the Orange or the Lemon, and is seldom agreeable to those who partake of it for the first time, "but, as in other instances, it becomes enjoyable in time."

"THE GARDENER."—One more periodical to add to the twenty-one (see *Willing's Press Guide*) devoted to gardening, and yet not one more, for with *The Gardener* is incorporated *Cottage Gardening*, formerly published by Messrs. Cassell at ½d. a week. *The Gardener* is issued by the same firm at one penny. Paper and print are good; the articles, if we may so call them, are mostly scrappy, but lightly touched, and readable. American methods have been copied in some cases. Whether they will be to the taste of English readers remains to be seen. A first number seldom or never affords a fair criterion, but we have never seen a more promising one than this, and we wish it every success.

TESTIMONIAL TO MR. J. WALLIS.—The many horticultural friends of Mr. John Wallis will regret to hear of his retirement from the position of head gardener at Keele Hall, Staffordshire, owing to the untoward circumstances that have overtaken this famous establishment. It is the desire of the present owner, we believe, to let Keele, and in the meantime the gardens will not be maintained in their former condition. Some of the young gardeners who have been associated with Mr. Wallis at Keele, where he has been upwards of twenty years, are raising a testimonial in his favour, as an expression of their esteem. Subscriptions may be sent to the Honorary Treasurer, Mr. H. V. Boothby, Keele, Staffordshire.

---

* *Handbook of Hardy Trees, Shrubs, and Herbaceous Plants, &c.* (Longmans.

Rain Still Wanted.—The month of March was unusually dry, and winds were frequent. Cultivators hope for considerable showers during April.

Rose Shows in the Present Year.—The following is a list of fixtures kindly furnished by Mr. Edward Mawley, Rosebank, Great Berkhamstead, Hon. Secretary of the National Rose Society. It comprises all Rose shows, or shows in which Roses form a feature, the dates of which are definitely fixed that have as yet reached him. He will be glad to receive the fixtures of any Rose shows not named below, or those of any horticultural exhibitions where Roses are made a leading feature, for insertion in future lists. June 14 (Wednesday), York (three days); June 24 (Saturday), Windsor; June 27 (Tuesday), Westminster (N. R. S.); June 28 (Wednesday), Bath and Croydon; June 29 (Thursday), Canterbury, Eltham, and Norwich; July 1 (Saturday), Crystal Palace (N. R. S.); July 4 (Tuesday), Gloucester and Harrow; July 5 (Wednesday), Ealing and Hanley (two days); July 6 (Thursday), Colchester (N. R. S.); July 11 (Tuesday), Hereford and Wolverhampton (three days); July 13 (Thursday), Brentwood and Helensburgh; July 20 (Thursday), Salterhebble; July 25 (Tuesday), Tibshelf.

Presentation.—Mr. C. W. Knowles, who for the past seventeen years has occupied the post of head gardener at Solna, Roehampton, and who was recently appointed to a similar position at Bagshot Park, the Surrey residence of H. R. H. the Duke of Connaught, was recently presented by some of his many friends with a clock in a marble stand, and furnished with an appropriate inscription. G. H. Pitt, Esq., the treasurer of the Putney, Wandsworth, and district Chrysanthemum Society, made the presentation, remarking that it afforded him great pleasure in handing over the present, which was but a very small token of the esteem in which Mr. Knowles was held by his many friends. Mr. Knowles in feeling terms thanked Mr. Pitt and his friends for the handsome present, and said, though as a time-keeper it would always remind him of the valuable slice from his life spent amongst them, it would also be a reminder (if that were necessary) of the pleasant associations and the many staunch friends he had formed in Putney and neighbourhood.

Her Majesty and the Gourds.—On Sunday last the Queen visited the *Festin des Congourdons*, or sale of Gourds, at Nice; but the event being held on the Sabbath, she made no purchase.

Presentation to Mr. T. Turton.—When it became known that Mr. Turton was leaving Maiden Erlegh for Sherborne Castle, Dorset, it was felt by his numerous friends that the occasion was suitable for evincing the high esteem and regard in which he was held. The result was shown on Wednesday, March 22, when Mr. and Mrs. Turton met a few of the Committee at the Abbey Hall, Reading, to receive from the hands of Mr. C. B. Stevens (the President of the Gardeners' Mutual Improvement Association), the presents set forth in the following address:—"Your numerous friends join in offering their hearty congratulations on your important appointment to the position of head gardener at Sherborne Castle. At the same time they are conscious of the great loss the Reading District will sustain by your departure from Maiden Erlegh. In the prominent position you have occupied as Chairman of the Reading Gardeners' Association, and as a member of the committees of the Reading Horticultural and Reading Chrysanthemum Societies, horticulturists have had the benefit of your knowledge and wide experience. Especially do they ounger men feel indebted to you for wise guidance and assistance on numerous occasions. It has been felt that your departure cannot be permitted without an expression of the high regard entertained for you as a successful exhibitor, a generous comrade, and a true friend, and you are now asked to accept the accompanying gold watch and chain with a purse of money as a token of good-will and esteem from those friends whose names are hereafter appended. We also beg Mrs. Turton's acceptance of a tea and coffee service." There were upwards of one hundred subscribers to the testimonial.

Linnean Society.—At the meeting of this Society held on March 16, 1899, Dr. A. Günther, F.R.S., President, in the chair, Dr. John Lowe, F.L.S., communicated some observations on the fertilisation of Araujia albens, G. Don, a Brazilian climber. Last summer it was blooming freely in Lord Ilchester's garden at Abbotsbury, where the flowers were visited by numbers of butterflies, diurnal moths, humble-bees, wasps, and large flies, many of which were captured and imprisoned for a time in the pinching-bodies (Klemm-körper of Müller). All these insects, with the exception of some humble-bees, in their visits to the nectar left their proboscis behind, and sometimes a leg, being not strong enough to detach the pinching-body. Dr. Lowe described the structure of the pinching-bodies, which are flat horny plates, situated above the nectar-cups, at each angle of a 5-sided hollow cone in the centre of the flower, in which is placed the stigma. There is only a small opening at the apex and a narrow slit at the base of each facet of the cone. To the upper point of the pinching-body the pollinia are attached. When an insect has its proboscis caught in the slit, which narrows always to its point, it can only escape by tearing away the body with its pollen-masses, or by leaving its proboscis in the slit. In the former case it carries the pollinia to the next flower it visits, and thus effects cross-fertilisation by leaving the pollen mass between the anther-wings, whence it rapidly passes into the cone. He had received a number of flowers of Araujia from Mr. Benbow, the gardener at Abbotsbury, in some of which he found the proboscis of a butterfly or moth in each of the five angles of the cone, showing the great destruction of insect life caused by the plant. Mr. N. E. Brown, A.L.S., who has made a special study of the Asclepiadaceæ, gave an interesting account of the manner in which the pollinia reach the stigma and some further remarks were made by Mr. A W. Bennett.

—— On the occasion of the evening meeting, to be held on Thursday, April 6, 1899, at 8 p.m., the following papers will be read—1, "On Carex Wahlenbergiana," by Mr. C. B. Clarke, M.A., F.R.S., F.L.S., &c.; 2, "On the Discovery and Development of Rhabdites in Cephalodiscus," by Mr. F. J. Cole.

Hooker's "Icones Plantarum."—Part IV. of the sixth volume (March, 1899), of Hooker's *Icones*, edited for the Bentham Trustees by Sir W. T. Thiselton-Dyer, contains illustrations of several plants of botanical interest. Among them various species of the Euphorbiaceous genus Hevea are given. The floral details of some of these are singularly like some of the Malvales or Sterculiads. Odontospermum pygmæum, t. 2583, is a desert Composite, shrivelling in dry weather, but expanding when the rain comes, hence it has been (with others) called the Rose of Jericho. Mr. Hemsley contributes further details relating to the extraordinary Pandanad named by him Sararanga sinuosa.

Fruit from the Cape.—The officials of the Union Steamship Company inform us of the arrival of the ships *Hawarden Castle*, and *German*. The former brought 725 boxes of Grapes, 7 of Plums, and 36 of Quinces; total, 768 boxes. The Grapes were all rather wet, and realised low prices; some were altogether poor and bad, and sold for a nominal figure. The Quinces arrived in good condition, but no market could be found for them, so they were sold to private individuals. The Plums were small, and in good condition, realising fair prices. The *German* brought 420 boxes of Grapes; only 107 of these were placed on the market, 40 boxes realising fair prices, being in good condition; 67 boxes were very bad, and sold for a mere nothing; 303 boxes were consigned to private individuals.

International Horticultural Exhibition at Mont St. Amand, Ghent.—The schedule of this exhibition, which opens on April 30 next, comprises 868 classes. Prizes to the amount of 40,000 francs (£1600) are offered, as well as "objets d'art" varying in value from 100 to 500 francs (£4 to £20). M. Madou offers for competition a dinner service for 24 persons; ninety-eight gold, and 148 other medals will also be awarded, including medals from the King and Queen. Enquiries should be addressed to M. Poelman-Maenhaut, Secretary of "L'Union," Mont St. Amand, Ghent.

Paris Chrysanthemum Committee.—The February number of this committee's *Journal* is unusually bulky, containing, as it does, eighty-seven pages. Among its contents is an article by M. Ernest Calvat on obtaining big blooms, than whom few perhaps are better qualified to speak in France. The report of the committee's work for 1898 then follows, part of which is devoted to a tabulated list of First-class Certificates awarded. There are also reports of an early-flowering show in Paris on October 13 last, and of local Chrysanthemum gatherings at Langres, Cognac, Troyes, Paris, &c. There are several illustrations, and a list of members concludes a somewhat interesting number.

Publications Received.—*Manual Pratico do Viticultor Brazileiro*, pelo Dr. Campos da Paz (Rio de Janeiro, Imprensa National).—*Transactions of the Royal Scottish Arboricultural Society*, vol. xv., Part III. This includes papers on the "Establishment of State Model Forests for Scotland," expressing the opinions of French and German experts on the present forestry system; working plan for the pit, wood working circle, Raith estate; Recent investigations in Prussia in regard to the quality of timber, &c.

HOME CORRESPONDENCE.

Eucalyptus Gunnii.—The seeds of this hardy tree were first sent me by my friend, David A. Shennan, of The Estancia, Negrete, Argentina, in 1887, who has naturalised various non-American plants on the southern part of the province of Buenos Ayres. Realising that unless perfectly hardy they were useless to me, I gave them their first transplant in September, 1887, when about 10 inches high, to a newly-trenched hill-top of the poorest gravel soil with northern exposure, among a sowing of Carrots. They throve, or most of them did, from the first, and soon began to make wood, flowering in their fifth year from seed; the buds, just like Fig-buds, appear on the shoots of 1899, only to burst into flower in 1900. I have some 500 to 700 plants planted out in woods, &c., raised from English seed, and have given away many more. The plant comes originally from the south end, i.e., the coldest, stormiest, and most exposed end of our southernmost Australian colony, Tasmania, a part of the colony where you realise the fact of the South Pole. The lot originally sowed have reached a maximum of 45 feet in height in twelve years, and a girth of 31 inches 4 feet from the ground. Had I planted them in better soil, or in a peaty wood, as I have since done, the results would have much exceeded this. The drawbacks to planting E. Gunnii in a cover is, that they attract mightily both hares and rabbits, and, in fields, sheep; that they are apt to overgrow their power to stand upright, and want stakes for a year or two—or some of them do. They vary much in habit, some being bushy to the ground, some bare for, say, 30 feet. The best I have (of the junior or pure British breed) has got his roots into a grave, whose tenant died of small-pox, in the parish churchyard, and it enjoys the situation hugely; he affects the bushy type. The hard winters of four or five years ago touched up some trees, which lost a year's growth, but regained it in the next. Brightlingsea village will be remarkable in, say, 1950, with hardy evergreen Gum trees, 160 feet high, as I give seed to all the inhabitants who want it, and many are growers. Cheshire (Mr. Egerton Warburton), Monmouth (Mr. Reginald Herbert), Suffolk (Sir Cuthbert Quilter), Huntingdon (Mr. Newton), Lincoln (Lord Ancaster), Devon, Surrey, and Essex in particular, have been trying the experiment with Essex-grown seed. The wood is hard, and presumably valuable. *John Bateman.*

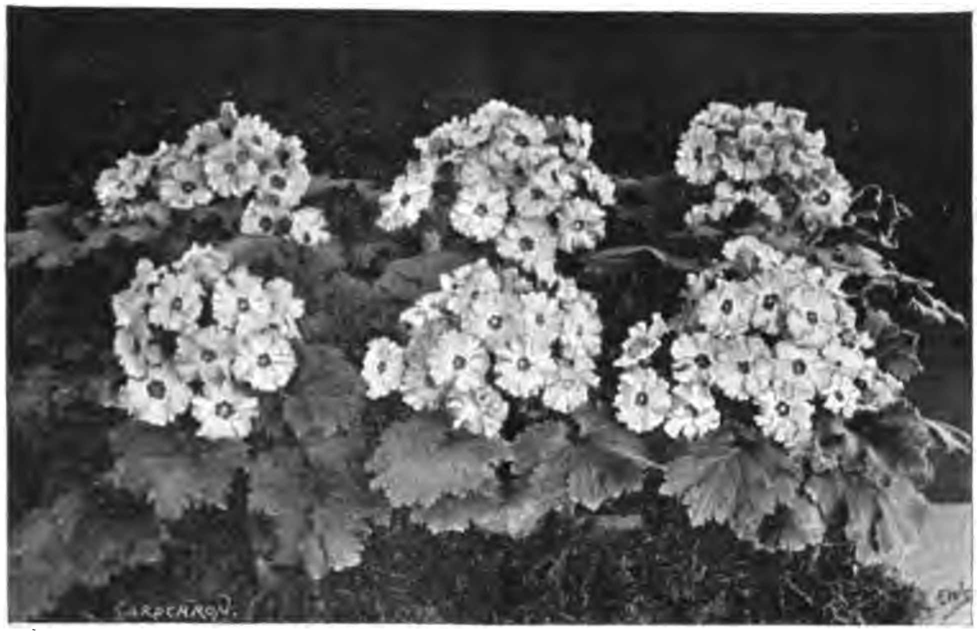


FIG. 77.—CHINESE PRIMULA "SWANLEY GIANT": A LARGE-FLOWERED FORM OF THE OLDER VARIETIES; PINK OR PURPLE IN COLOUR.

From a photograph from Messrs. H. Cannell & Sons. See article in our last issue, p. 179.

PODOPHYLLUMS.—The best description I can give of the manner these plants push through the ground in the spring, is to say that they rise from thence like a folded umbrella, and when the stalks are high enough, expand in the same way as umbrellas are unfolded, with the difference that the solitary circular leaves become flattened but round. I received my plants from the greatest American Shakesperian authority, collected, I believe, in the country around Philadelphia—a sure proof of their being very hardy. The flowers are singular owing to the nakedness of the prominent seed capsule—a large white Poppy in form, but bereft of its stamens. P. peltatum develops yellow fruit in its native habitat. This I have not seen on home-grown examples. Podophyllum Emodi is of larger growth, the leaves being distinguished by black spots. It produces, moreover, large berries of a bright scarlet colour. Both species succeed best in a moist peaty soil. *William Earley.*

POTATOS: SYON HOUSE PROLIFIC.—In Mr. J. B. Joel's garden at Northaw House, Barnet, I was recently shown a fine sample of this variety, and to satisfy my enquiry as to their flavour I was given a dozen tubers, half of which I had baked, and the other half boiled, and in both cases I found them to be of the very finest quality. Mr. May, the gardener, who has taken many prizes at the Royal Aquarium shows for Potatos and other vegetables, speaks of Syon House as being the best recent introduction which has come under his notice. Gardeners do not, as a rule, record their experience of new varieties of Potatos sufficiently, and they might give much greater publicity to little-known sorts. Syon House was raised by Mr. Wythes, and received an Award of Merit by the Royal Horticultural Society in 1895. The tubers are inclined to be oval in shape, with small eyes, and from what Mr. May told me, it is one of the latest keeping varieties. *H. M.*

PASSIFLORA RACEMOSA SYN. PRINCEPS.—I was pleased to note the favourable notice of this beautiful and useful Passion-flower from the pen of "E. S.," in the *Gardeners' Chronicle*. So far as I remember, it is the only one that blooms in racemes, and the habit, character, and colour are all that can be desired as a climber on a glasshouse roof or wall. The foliage is distinct and striking, and goes well with the characteristic flower. In cutting the flowers of this plant for decorative purposes, the shoots should not be cut hard back, as when a half-inch or so of shoot is left, one or more racemes of blossoms will come on it, after the manner of Hoya carnosa. Though I have chronicled this fact before more than once, it does not seem to be generally known nor acted upon, hence my allusion to it here. The species may be severely pruned by closely spurring the young shoots back to the older shoots, as by so acting a great number of fine blooms are produced. It is pitiable to see this fine plant so mismanaged as to be a mere tangle of shoots and bracts, with but few perfect flowers, and these perhaps crushed against the glass. The blooms are very effective for the furnishing of vases, baskets, epergnes, &c., inasmuch as the bracts and unopened flower-buds, or the drooping racemes, are almost as beautiful as the fully expanded flowers. *D. T. F.*

THE SHAMROCK.—If your correspondent, "D.," will refer to the *Cybele Hibernica*, ed. 2, p. 159; *Irish Naturalist*, 1892, p. 95, and 1893, pp. 207, 349 to 361; *Journal of the Proceedings of the Royal Society of Antiquaries of Ireland*, vi., 211 to 226, 349 to 361; or to the *Dictionary of English Plant Names*, 425, or to the first Irishman he comes across, he will learn that the Wood-sorrel has no claim to be considered the Shamrock, in spite of its trifoliate foliage. Considering how much careful investigation has been bestowed by Mr. Nathaniel Colgarn and others upon this interesting antiquarian subject, it is, I think, to be regretted that literature should be encumbered by notes such as that printed on p. 189. *James Britten, British Museum.*

PROSPECTS OF FRUIT-CROPS.—Here at the present time there are prospects of an abundant crop of hardy fruits. In many cases the number of flower-buds is so great that I am doubtful if it is not the reverse of a blessing, as trees thus loaded with bloom not unfrequently fail to crop so well as those on which there is only a moderate show. Trees, however, which grow on a deep strong soil, as ours, are not so liable to fail from superfluous flowering, as those which may have their vitality enfeebled by drought acting on shallow, light soils. Trees on a clay soil are more robust and naturally stronger, and their sufferings from lack of moisture less trying. What is to be feared is frost at the flowering time, which ruins our hopes when every other condition may be in favour of a good crop. [The recent frosts have occurred since this paragraph was written. ED.] Last year there were complaints in some districts of Plum-trees having suffered from drought, but nothing was harmed excepting Strawberries. Strong growing varieties of fruit-trees were benefited, on the contrary, by the check the heat and dryness caused, which acted on them in a manner similar to that caused by root-pruning. In a garden planted with pyramids and bushes in 1893, the Pears this year are unusually promising, even kinds which cropped heavily last year are prolific of flower-buds. Of this I may name Baronne de Mello, Beurré Diel, B. Fonqueray, B. Hardy, Doyenné du Comice, and Louise Bonne of Jersey. Whilst Catillac, Bellissime d'Hiver, Marie Benoist, Souvenir du Congrès, Triomphe de Vienne, and Josephine de Malines, usually shy bearers, are thickly set with flower-buds. It may be remarked that the last-named, owing to its flowering upon the points of the shoots, is better as a pyramid, or bush, than as a trained tree against a wall, or as a cordon, or espalier. Of Plums, Denniston's Superb, Rivers' Early Prolific, Grand Duke, Jefferson, Kirkes, and Oullin's Golden Gage, afford the finest show of flower-buds. The Czar, Monarch, and Pond's Seedling, having the fewest. Cherries are likewise promising, especially Belle Magnifique (a prolific form of Morello), May Duke, and Late Duke. Apples with the following exceptions are very promising, Annie Elizabeth, Dutch Mignonne, Gascoigne's Seedling, Gloria Mundi, Lady Sudeley, Lord Burghley, and American Mother. A row consisting of thirteen trees of Bramley's Seedling, which in no year have borne more than a few fruits, are well furnished with flower-buds, a result of a severe pruning of the roots, carried out in the autumn of 1897. *Thos. Coomber, The Hendre Gardens, Monmouth.*

NEW AND OLD VARIETIES OF THE POTATO.—The Potato, like many other vegetables, has been greatly improved in the last thirty years. It used to be thought that nothing surpassed the Ashleaf variety in flavour, and many persons will have it at their tables as long as it is possible; and after this variety is past, then they rely upon Magnum Bonum, which lasts in good condition till the Ashleaf comes in again—two good Potatos, no doubt, which would take a lot of beating if only two were to be grown. But if the garden is not large enough to allow of the Ashleaf being planted in sufficient quantity to supply a large household, then other more prolific croppers must be planted, and Ashleaf be grown only for the best table. I put nearly as much value upon a good late Potato as upon early ones; in this way, when the demand is large, digging must not be started till the supply is equal to the demand. This can be easily effected if but Magnum Bonum and Up-to-Date are planted; as these are valuable varieties of good quality, until the month of July if necessary, and therefore after New Potatos are fit for consumption. Usually the cook is glad of some firm old Potato for making up dishes. If there is plenty of ground at command, new varieties should be tested; but those who are restricted in that particular, perforce have to rely upon the experience of others, as related in the gardening press, &c. The following have been tried at Compton Basset, and found excellent, namely—Sutton's Harbinger, Ringleader, Early May, Sharpe's Victor, Carter's First Crop, Advancer, and Early Favourite; these are early, free-cropping varieties, of good quality. As Main-crop varieties, cropping well, of excellent quality, and capable of resisting disease to a certain extent, are Carter's Snowball, a very fine Potato, a cross between Schoolmaster and The Canon, of nice shape, round in form, with shallow eyes, and a rough skin, white when cooked, of the finest quality, and a heavy cropper; Carter's Monarch, also raised from Schoolmaster, an excellent round Potato; Ideal, a prodigious cropper, very handsome, well suited for exhibition, and yet excellent for the table; Sutton's Windsor Castle, a heavy cropper, and resisting disease; Sutton's Reliance keeps well, and crops splendidly, a fine exhibition tuber, not liable to take the disease; Magnum Bonum Improved, a most trusty variety for a late supply; Up-to-date, a late Potato, and a huge cropper, with large tubers, good for field culture, nice flavour, and keeping till a late date, one of the heaviest croppers extant. Nothing is more injurious than close cropping, and I afford a space of 3½ feet between the rows, so that I can interline with other vegetables. Late varieties of robust habit at this distance produce large crops, and being less crowded are not so liable to become diseased as close-planted rows. I find there is no manure equals that from the farm-yard, laid on the land before digging it; blood-and-bone manure being afford at planting-time at the rate of 6 to 10 cwt. per acre. *W. A. Cook, Compton Basset.*

APPLE MANNINGTON'S PEARMAIN. — This fine late dessert Apple is considered to be one of the richest and best-flavoured of table varieties. It is now a very old variety, having, according to the *Fruit Manual*, originated as far back as 1770, in a garden which twenty years ago was in the possession of Mr. J. Mannington. It is supposed to have originated as a chance seedling, for the tree was found in a hedge-row, a small scrubby specimen, on a spot where a cider-mill and press were formerly worked, and is supposed to have been produced from a pip or kernel from the pulp thrown away after pressing. This tree never attained to any great size, but continued to preserve a stunted habit of growth till it died, about the year 1820. Grafts were taken from it, and so the variety remained in the neighbourhood until the autumn of 1847, when specimens were sent to the London Horticultural Society, and Mr. Thompson named it Mannington's Pearmain. It was them distributed by Mr. Cameron, nurseryman, of Uckfield, Sussex, who said of this Apple that "the fruit should be allowed to hang late upon the tree before it is gathered, so as to secure its peculiar richness of flavour, and long period of duration; for if gathered too soon, it loses much of its fine richness, and is very apt to shrivel. This must have been the case with some fruit which came into my possession a short time since; a few were shrivelled, the flesh hard in texture, and wanting in flavour, while the plump fruits, apparently more matured, had that rich flavour peculiar to the variety. Dr. Hogg's description of the habit of growth is confirmed by experience:—"The tree does not attain a large size, but is perfectly hardy, and an early and excellent bearer, young trees, only two or three years from the graft producing a considerable crop of handsome well-grown fruit. It was first put into commerce in 1849 by Mr. Cameron, dwarf, maiden trees being sold at half a guinea each. *R. D.*

SEQUOIA GIGANTEA AND OTHER TREES.—A good specimen of the Wellingtonia compels admiration. Have many of us reflected what root-anchorage the tall, graceful specimens seen occasionally require to keep them in an upright position? Having occasion recently to move one that was growing on the estate of E. S. Hanbury, Esq., Hertfordshire, my curiosity was somewhat satisfied on that point, the number and size of the roots being surprising. The tree in question was not a very tall one, the height being 42 feet 8 inches, and the circumference 3 feet from the ground measured 7 feet 9½ inches. Through some cause or other it unfortunately lost its leader many years ago, that being one of the reasons for now removing it; besides which, it spoiled the view obtainable of the adjoining trees. The soil and subsoil vary very much at this place, but this particular tree had been planted on a bed of clay, which had to be chipped away with pick-axes, so hard and dry had it become round the base of the tree. I should be glad to know if any one in England has felled so large a specimen of this species. There are other trees of the same variety here, one being upwards of 70 feet in height, 12½ feet in circumference 3 feet from the ground, with a spread of branches 30 feet in diameter. The collection contains some good specimens of Cedrus atlantica and C. Libani, the former being remarkable for their glaucous appearance. Sequoia sempervirens is also represented, one specimen measuring 9 feet 2 inches in circumference 3 feet from the ground, and being at least 50 feet in height. It is densely furnished with branches from top to bottom. *A. W.*

SKIN IRRITATION CAUSED BY PRIMULA SINENSIS LEAVES.—Is it generally known that Primula sinensis is quite as liable to cause irritation as the Primula obconica? my attention has been called to the fact by a gardening friend of mine, the skin of whose hands and arms was so irritated that he could not get any rest for several nights; the variety in question was Rosy Queen. It would be interesting to hear if you or any reader of the *Gardeners' Chronicle* have ever heard of a similar case. My friend, I may state, grows no other species of Primula than P. sinensis. *J. R. Wilson, Haselbech Hall Gardens.*

AN ADVERTISER'S COMPLAINT.—I applied for a vacancy for a head gardener, which was recently advertised. With my letter I enclosed testimonials for inspection. In two days the testimonials were returned in an unstamped envelope, for which 2*d.* was charged by the postal authorities. There was not a word inside to say if the sender was suited or otherwise. I wonder if any other advertiser has had a like experience. I enclose envelope for your inspection. *A. J.*

THE ROYAL GARDENERS' ORPHAN FUND. — As your correspondent, Mr. J. B. Stevenson, has referred so pointedly to me in his recent communication on the above subject, I would like to explain that I agree with him that single candidates from any family should always have preference over a second candidate from the same family, although now and then cases do occur in which there may be but one, or two at the most, orphan children in a family, and in another, four or more quite little ones; and where that is so, such a case is a more distressful one than is the first. But my suggestion made at the general meeting, viz., that there should be at least four children under twelve years of age to entitle a second to become a candidate, was meant to strengthen the hands of the committee, as evidently that body was scandalised on finding an effort made to put a third child from one family on to the Fund, practically exploiting it in a most improper way, whilst I felt equally scandalised to find the only two children of one family were both nominated; and such an amendment as I suggested would have in future rendered such nominations impossible. I hope the committee will agree to give effect to this proposal as an amendment to the rules at the next annual general meeting. With respect to the objections gardeners entertain against subscribing, some are of a nature it would not be well to publish. Some are based on one thing; not a few on distrust in connection with the elections; but the greater portion is based on absolute indifference. Men who have little ones think their children will never want the Fund's benefits, and because these men will not subscribe, others shelter themselves behind the objection that if fathers of little ones will not try and help themselves a little, why should they? With our philanthropy, we are in danger of bringing those who should try to help themselves into a condition of utter indifference. *A. D.*

CARNATIONS EATEN BY THE SPARROWS. — Although the winter favoured the Carnation out-doors, some cultivators in my neighbourhood have had to contend against a plague of sparrows, and so serious is the mischief wrought, that scarcely a plant has escaped their attention. Several collections I have observed lately present the same appearances as my own. At first I was at a loss to account for the damage, as although rabbits are numerous, the Carnation-beds are surrounded by rabbit proof wire-netting, 4 feet high. At length, I discovered the miscreants were sparrows—no fewer than six of the birds could be seen at times pecking the plants. The damage inflicted is almost as great as that caused by a rabbit. The best deterrent is soot dusted on the leaves when moist. A Carnation plant is sent for your inspection. *E. Scaplehorn, Woking.* [The leaves and small shoots were closely nibbled, as if by a rabbit. It would be well another year to plant Lettuces or other herb more succulent than the "grass" of the Carnation, as "tit-bits" for the sparrows, and thus wean them of their naughtiness. Our own Carnations have suffered in a similar manner, but we are not sure whether, in our case, pigeons are not the culprits. Ed.]

HARDY FRUITS AND THE WEATHER. — Last spring, during the flowering-time, sharp frosts, accompanied by snow and rain, played great havoc with the various kinds, and I fear that this year full crops will be the exception, not the rule, unless we get more genial weather. The week which ended on March 25 was most exceptional for downright wintry weather, 12°, 14°, 18°, 16°, 14°, 16°, 17°, of frost respectively, with cold biting winds, and storms of snow at intervals, were experienced on successive days. By the accounts in the papers we do not seem to have had so heavy a snowfall as in other parts. The storms in this locality were of short duration, and the snow was rapidly dispersed by the sun. Apricots and Peaches have about half their blossoms expanded, but I do not think these have suffered much, so far as can be seen, being well protected by wall copings and fish-netting. The blossom-buds of Pears and Plums, with the exception of one or two of the earlier flowering varieties are still unexpanded. Small fruits are late this year, and the leaves have but just began to unfold. All kinds of hardy fruit-blossoms have a promising look. *Geo. Woodgate, Rolleston Hall Gardens, Staffordshire.*

THE WEATHER AT BATTLE, SUSSEX.—The following is a record of the amount of frost registered by thermometer in the gardens at Battle Abbey, inside the walls, at 3 feet from ground:—19th, 12°; 20th, 12°; 21st, 18°; 22nd, 22°; 23rd, 14°; 24th, 14°; 25th, 17°. Peach and Plum-trees on south walls were in full bloom, and covered with hexagon netting, do not appear at present to have suffered much. A welcome change set in on Saturday. *Wm. Camm.*

—— **IN NORFOLK.**—On Wednesday, March 22, the wind continued to blow strongly from the north-west, and the air was very nipping in the shade, although there was a good deal of sunshine. The wind died away before midnight, and our Negretti & Zambra thermometer had fallen to 24° two hours earlier. The lowest reading on Thursday at 6.30 A.M. showed 12° of frost, and snow fell between 7 and 9 A.M. to the depth of 1 inch, the wind backing to the south-ward. It is now calm, and the worst seems to be over. *J. Batters, Gillingham, Norfolk.*

—— **IN THE MIDLANDS.**—We were visited on Tuesday, March 21, with a very heavy snow-storm, accompanied with severe frost, the effects of which will, I fear, prove disastrous to the fruit crops, more especially Apricots, Peaches, and early Pears. In these gardens those trees are protected on walls with a double thickness of fish-netting, and in winters of ordinary severity this protection suffice; but now, with such unprecedented weather, the fruit-blossoms have a burnt look. About 3.50 P.M. on Tuesday the sky suddenly became overcast, the wind rose, and darkness set in, and large flakes of snow fell quickly, covering the ground. The rapidity with which the thermometer fell was marvellous. The reading at 7.30 showed 16° of frost, which is as low a degree of cold as has been registered here this winter. On Wednesday morning it showed 18°. The barometer has remained nearly stationary during the week, the maximum being 29·70 inches. On Thursday it is steady at 29·58 inches, and snow is falling rapidly. The previous mildness caused vegetation to advance rapidly, and it will be very surprising if the fruit-blossom is not irreparably damaged. *H. T. Martin, Stoneleigh Abbey Gdns., Warwickshire.*

MARKET GARDENING IN THE CHANNEL ISLANDS: JERSEY.

(*Continued from p. 116.*)

Bagot Manor.—On Monday, September 12, I was taken to the establishments of Mrs. Bashford, one of the largest fruit-growing places in Jersey. The space covered with glass is very great, and the quantity of produce constantly sent away reaches very high figures. Tomato Bashford's A 1, a well-known variety grown here, invariably commands a higher figure than any other variety in the market. The situation seems to be adapted to the cultivation of the various subjects, and with care and sufficient labour bestowed good returns are reached. The produce consists almost entirely of Pears, Grapes, Tomatos, Kidney Beans, and Potatos, with an occasional crop of Cucumbers or Melons. Of these four last-named kinds, there were few signs just at the time, though the multitude of boxes of Seed Potatos standing in shady places out of doors, clearly showed that this branch of labour was shortly to be engaged in. The first three named, claimed daily attention.

The Tomatos were found in splendid condition, house following house, and such houses, too. In one block there were six houses, the smallest being 300 feet by 36 feet, increasing in size according to the amount of space at command, to 500 feet by 40 feet. The plants are set out, sometimes, across the houses; in others the rows run right through, from end to end, and so, looking at one end, avenues of plants reach the whole of the distance.

The morning of my visit 150 baskets had been sent away, each basket carrying 10 to 14 lb. of fruit. The gathering, sorting, and packing of this quantity of fruit is no small task; but no sooner has this lot been dispatched from one side of the establishment than gathering is taking place in the other part, and ere I left I saw another lot being packed, &c., so that the next morning another hundred baskets would be put on the steamer.

As may be supposed, the fruit, though coloured, is not dead ripe, and it bears the packing and transit well, so that a bruised fruit is scarcely ever found. Great care is bestowed on the packing of the baskets; the bottom has a layer of paper shavings, on which fruit is laid, then other layers of shavings and fruits, till the basket is brim full, the whole is then covered with several layers of tissue paper, laid all round the inside, and well secured by string, laced several times across the top; a label is attached, and the basket is ready for its journey of 200 or 300 miles. It is no unusual thing to have one or more baskets in each boat taken by the customs officials at Weymouth and Southampton and carefully examined, the basket untied, the top paper removed that the contents may be seen, the coverings then are replaced and tied tightly down again, and passed on with the others.

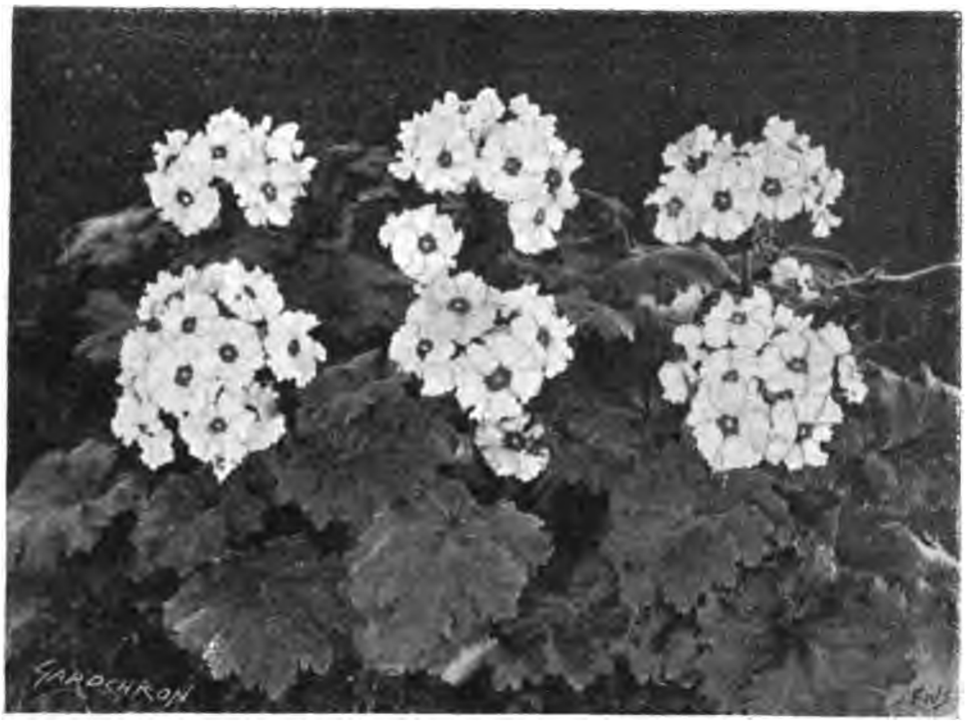

Fig. 78.—Chinese primrose "Her Majesty."

From a photograph from Messrs. H. Cannell & Sons. See article in our last issue, p. 179.

As soon as the Tomatos are finished, the borders in the houses are prepared for planting Ashleaf Potatos, the planting of which takes place in November. This crop comes quickly forward, and as soon as the tubers are ready they are dug up, packed, and sent away, the many persons now engaged in this business causing the scenes at the landing-stages to be unusually lively. During the season, from April to July, when those outside follow so quickly the crop from the houses, the harbour of St. Helier is full of life and bustle, the whole of the quays being occupied with vessels, often berthed two or three deep, taking their freights on board. The Potatos, packed in barrels and basket hampers, are brought down to the steamers in the farmers' vans, and it is not an uncommon sight to witness a procession of these vans a mile in length awaiting their turn to unload.

And now we look in at some of the vineries; here is a house devoted entirely to Muscats, from which no less than 5 tons have been gathered and disposed of. Some 11,000 bunches had been cut, and as this variety always commands the highest price, the value of such a crop may be readily grasped. These Vines are twelve years old, in good heart, with canes and buds stout and plump, the roots being inside and outside. As may be imagined, a great deal of labour is bestowed on such a house, besides which, some 30 tons of farmyard-manure are used as a top-dressing inside, and considerable quantities on the outside border also. This inside mulching forms but a slight covering, and superphosphate of lime, guano, and other manures, are freely used. It is surprising to see the number of bags of these manures in many of the sheds, the agents for these essentials, will, I doubt not, find in the islands a good outlet for much of their goods. Another house of Black Hamburgh Grapes, 450 feet by 36 feet, was seen; and then we had a look inside a house known by the "Three 7's," this being just 777 feet long, in which the first crop to be taken was to be Potatos planted in November. As soon as this crop is lifted, say in April and May, Sutton's Climbing and Canadian Wonder Kidney Beans are sown, and when these have produced their crop, Tomatos are planted; thus, three good crops are secured in one year. A houseful of Gros Colmar Grapes was just in the colouring stage.

And now, as one hive of industry is passed for another, Pear-trees came constantly in view; in fact, almost every available spot is occupied by them. The wall-trees were a wonderful sight; one wall being 1200 feet long, and almost the entire surface is covered with trees of Doyenné du Comice, Beurré Clairgeau, Uvedale St. Germains, EasterBeurré, &c. The first-named variety occupies the largest amount of space, and the fruit would weigh from 1 lb. to 1¼ lb. each. Many of the finest fruits for safety's sake were covered with muslin bags. Trees on walls of Louise Bonne of Jersey and Winter Nelis were also carrying a fine crop, but these varieties are less grown on the island. The trees were pictures of good culture. There was a large number of pyramidal trees 5 to 10 feet, the lower lateral shoots removed, those at the upper part alone remaining, and the fruit on these trees was in grand form, abundant and large. These consisted of Williams' Bon Chrétien and Pitmaston Duchess varieties, that exist in great numbers of fruiting trees, the trees themselves not being for sale. The fruit was putting on the last patches and streaks of colour, so indicative of thorough maturity. Four tons of Williams' Bonne Chrétien had already been gathered and sent off, and daily gatherings were taking place. To go over these large quarters examining the whole, picking for to-day, and mentally noting those ready for the morrow, is a piece of work needing experience, diligence, and much practice. We came across large breadths of Doyenné du Comice and Williams', each tree a specimen, from which many fruits had been plucked, and a fair crop still hanging. Of "Williams," some 30 tons were gathered altogether, large fruit, regular in size, and of excellent flavour. The top-dressing afforded these trees is a special feature. More Chaumontels, which I was informed was not quite so large as in some former years; Catillac, Van Mons Léon le Clerc, and one or two others; the three varieties, Williams' Bonne Chrétien, Pitmaston Duchesse, and Doyenné du Comice, are those mostly depended upon. Doubtless soil and climate have much to do with the production of such fine fruit; but skill counts for much, and here it is exhibited in a high degree. A few varieties only are cultivated, viz., those which crop well in the generality of years, and travel 200 or miles away without loss or injury.

My guide was an intelligent native, whose years of service numbered about thirty. He alluded to his successes modestly, and to his disappointments with but a word, always cheery, and always anticipating better things next year; it was a pleasure to me to have met so sanguine a man. It was anticipated that ere this season closed 60 tons of Pears would be gathered, a ready market awaiting the fruit. How trying and hazardous the business is may be gathered from the fact that in one year 16 tons of fruit were gathered from one part of the grounds, and the year following but 16 cwt. were secured; so that disaster sometimes comes even to this sunny isle. It would need almost as much labour to attend to the trees when the hundredweights were gathered as when tons rewarded the owner. My notes still run on walls covered with fruit-trees, quarters of "Williams," Doyenné, and Pitmaston Duchess, grand fruits, heavy crops, thick mulching, free manurings, but I forbear. I was much interested, highly pleased, and now acknowledge my sincere thanks to my guides, both lady and manager. *From our Special Correspondent.*

(To be continued.)

THE MARÉCHAL NIEL ROSE.

A good deal may doubtless be done in the future as in the past to improve the health and extend the life of individual plants of this best and most fragrant of all golden Roses, through the mating of it with more suitable stocks, as so often suggested by different growers, and again, by "A. D.," and the Editor on p. 57. But after many years' experience, I much doubt if any mere question of mechanical mating or uniformity of growths between scion and stock will entirely cure the gout, warts, or wens which so often wreck and ruin its health, beauty, and life. Congruous mating of stocks with scions may modify this innate tendency—hardly cure it. This needs no further confirmation than the fact that the striking protuberances are by no means unknown on Maréchal Niel Roses on their own roots. The gout, or whatever else we may call it, lies deeper in the constitution than mere accidental mistakes of mating can account for. Its outbreak and development are more like a veritable and active disease in itself than any mere block or derangement of circulation through the vessels of this particular Rose.

Further, if this is the sole or chief reason for the gout, warts, or wens in this Rose, how is it that the disease is wholly confined to this variety, seeing that the faulty mating scion and stocks is one of the most common faults of cultivation. [We have remarked the same thing in Rose Mrs. Bosanquet. ED.] Not, however, that I would discourage the most skilful mating between scions and stock. On the contrary, I have tried almost all possible stocks, and not a few that might have seemed impossible. The stronger Teas, such as Homère, Gloire de Dijon, Marie Henriette, proved good stocks, though they did not wholly cure the gout out-of-doors nor under glass. It may also be added that standard Dog-rose stock about 3 feet high, grown for late autumn bloom on a north-east border showed little or no gout, and were invaluable for furnishing good supplies of golden Roses through August, September, October, and in mild winters well through November.

But so far as mastering or reducing this troublesome disease was concerned, my best stock was the yellow Banksian Rose. Those familiar with the two Roses will at once see that the roots or stems of the yellow Banksian Rose could hardly overfeed the Maréchal Niel.

Be that as it may, too exclusive attention has probably been concentrated on mere over-feeding, or irregular distribution of food supplies. Nor must it be too hastily assumed that any Banksian Rose will form an equally good stock for the Maréchal Niel. On the contrary, the white is not equal to the yellow, and the large white or Fortunei, which I have always held to be a true Banksian Rose spoilt, is the worst stock of the three Banksians. I do not advocate the yellow Banksian as a perfect cure for the "gout" among Maréchal Niel Roses, but the nearest to a cure we have yet attained. *D. T. Fish.*

MARKET GARDENING UNDER GLASS.

FRUITS.—Vines and Peaches in their various stages of growth require prompt and frequent attention—in the way of disbudding and training of the shoots retained for furnishing the trellis with bearing wood for another year. In these days of express growing, it does not take long to fill a vinery or peach-house with bearing Vines and trees treated on the extension system, that is, by allowing both Vines and Peach trees to make a free extended growth, simply removing superfluous and extra strong growths in due time in the case of Peach and Nectarine trees planted last and the previous autumn.

Young Vines which have been planted during the present month with the intention of securing fruiting Vines as soon as possible, should be given a high and uniformly moist atmosphere until the Vines have reached the top wire of the trellis, when a more airy and dry atmosphere will be beneficial in order to ripen the wood properly. Meantime, lateral growths should be kept hard pinched to one joint from the main rod, stopping the latter about three feet from the bottom wire, and pinching out the young growths resulting from this stopping in the axil of the top leaf. This will cause the bud or eye (which would otherwise remain dormant until another year) to push into growth. The temporary check thus given to the terminal growth causes that below to thicken, and the eyes in the axils of individual leaves to become plump. The operation being repeated two or three times during the period of active growth, good fruiting-rods and eyes of uniform thickness and plumpness will be secured for next year. With regard to the cropping of established Vines, the length and strength of the individual rods should determine the number of bunches that should be retained on each Vine for a crop. Indeed, so long as the Vines are in robust health and are generously treated by giving good top-dressings of some reliable artificial manure before applying water at the roots, it is surprising what immense crops such Vines are capable of ripening, at the same time making robust growth. However, one bunch may be left on each shoot with perfect safety, assuming that only one lateral was left to each spur at the time of disbudding.

The same remarks apply to the cropping of Peach and Nectarine trees. Where the trees are in the best possible condition, the fruit may be thinned out from six to eight inches on the tree as soon as a good set has been secured; and at this distance the fruits will come pretty close to each other by the time they are ripe, and reach top prices in the market notwithstanding.

FRENCH BEANS.

Remunerative crops of French Beans may be grown in the Vine borders without interfering with the welfare of the Vines in any way; the warm moist atmosphere being very suitable to them.

TOMATOS.

Where Tomatos are grown in the same house with Vines, the latter will take about three years to become fully established; the houses, being treated expressly for the Tomato, the Vines make a slow but sturdy growth in the dry airy atmosphere necessarily observed. *H. W. Ward.*

NOTICES OF BOOKS.

THE CULTURE OF THE CHRYSANTHEMUM.

By W. Wells.

THE handy little cloth-covered manual bearing the above title purports to be a new and revised edition of a former issue; but it is only fair to the author to say it is almost an entirely new publication, for it seems to have been in a great part re-written, enlarged, and more fully illustrated than its predecessor.

As a grower of big exhibition blooms, the author is certainly well qualified to speak, and his compendium now before us seems to cover the whole range of Chrysanthemum culture in all its phases. As instances of which, the titles of only a few of the chapters must suffice, viz., Stopping, and its Object; Early-flowering Chrysanthemums; Housing the Plants; Staging Flowers; Chrysanthemums for Market; Soil for Potting; Cutbacks; Insect-pests and Diseases; Dressing Blooms, &c. Some lists of good incurveds, Japanese, and novelties, are given, which may be useful to many readers, and the lists are rendered valuable by the addition of cultural information as to rooting, stopping, number of shoots, buds to be taken, and feeding. Altogether, Mr. Wells' new contribution to the bibliography of the popular autumn flower is worthy of perusal by those interested in the subject.

THE PRINCIPLES OF AGRICULTURE. A Text-book for Schools and Rural Societies. Edited by L. H. Bailey (New York and London: Macmillans; pp. viii. to 300).

Agriculture, we are told in the preface to this useful little book, is a business, not a science. "But at every point a knowledge of science aids the business. It is on the science side that the experimenter is able to help the farmer. On the business side the farmer must rely upon himself, for the person who is not a good business man cannot be a good farmer, however much he may know of science."

This remark is as applicable to horticulture as it is to agriculture; indeed the whole book, barring the section devoted to animals, is as suitable for the gardener as it is for the farmer. The subject is treated with some originality, as is shown by a statement in the preface to the effect that "the best part of the book is the table of contents." In so far as this shows an orderly, logical presentation of the facts, this remark is true; but, nevertheless, we think the best of all exercises for the student is not to trust to someone else's summary or table of contents, but to make the "analysis" for himself. Under the heading of The Soil, the reader is introduced to the contents of the soil, its texture, moisture, tillage, and enrichment. These chapters are written by different persons attached to Cornell University.

The second part of the volume is devoted to the plant and the crops, including the relation of the plant to its surroundings, how the plant lives, how it is propagated. the preparation of the land for seed, the subsequent care of the plant, pruning, training, the management of pasture lands. The remainder of the volume is devoted to the animal life on the farm. The book is clearly written, and well adapted for its purpose.

THE APIARY.

Avoiding Pollen in Sections.—With but few exceptions, pollen in sections has caused me some loss each season, and to a less extent sections containing honey imperfectly fastened also, but never before anything like this. A year earlier, under the same management, there was practically no loss from either cause. The season might, therefore, in some sense, be accounted to blame, but in order to make a success of the business at present, one must be able and understand how to meet the conditions of different seasons, and with such knowledge I have no doubt the loss might have been avoided. Admitting that I might not be able to entirely avoid it if the same conditions were to occur again this season, yet I consider what I learned in regard to the matter was of more benefit to me than what was lost, for I am a young man yet, and expect to follow bee-keeping as a business in the future. I will first say that pollen in this, my immediate locality, is very abundant through the entire season, but as this is used mainly in brood-rearing, the natural instinct of bees causes them, when conditions are favourable, to store it in the brood-chamber, where it will be easily accessible for this purpose. But the plan I follow with the swarms, either natural or artificial, is to hive them in a hive with frames containing "starters" only, when, if the supers from the parent hives (in which work has already commenced) are put in a day or two, work will be resumed in them at once, and a good queen will usually lay in a large part of the comb below as fast as it is built, so that most of the honey brought in is necessarily for some time stored in the sections. I do not believe there is any method by which as much honey can be secured in sections, and in a good season, or during a good flow; a swarm when first hived will not bring in much pollen for a few days. Last year the flow, except during the first few days, was very scanty and irregular, and as it was those swarms treated as described that put pollen in the sections; it will be seen that this method should not be practised during a poor flow in a locality where pollen is abundant, for when they cannot secure honey they will carry in an excessive amount of pollen, and must of necessity store it in the sections. Now, I have not much doubt that to give one or two frames in each hive containing drawn comb, then waiting until considerable comb was built in them before putting on the sections, would overcome the difficulty, or if no frames of drawn-out combs were on hand, a like number filled with foundation would probably prove effective. There is so much pollen here that colonies that did not swarm would ofttimes carry it into the sections, but years ago I accidentally learned how to overcome this almost entirely by changing the places of combs in the hive. This was done to discourage swarming. My practice is, at the approach of the swarming season, to replace the two outside combs with those that contain the most sealed brood, the two from the outside which usually contain a large proportion of what pollen there is in the hive, are then placed in the centre. If done at the right time this has a tendency to check swarming, and I soon

noticed sections over colonies so treated hardly ever contained any pollen. Such an abundance of pollen right in the centre of the brood-nest may possibly act as a check to their gathering much more for a time. However this may be, there would soon be plenty of room for them to store a large amount again in the last two outside combs. As to sections containing honey but slightly fastened to the wood, I believe there are means by which this can be largely avoided, no matter what the character of the flow is, and even if only small starters are used. But as this article is already so long, I will have to wait to explain my experiments in regard to this matter until some other time. *By Expert.*

SOCIETIES.

ROYAL HORTICULTURAL.

March 28.—The usual fortnightly meeting of the committees of this Society was held at the Drill Hall, Westminster, on Tuesday last, when, happily, the conditions of the weather were exactly opposite to those that prevailed a fortnight ago. But the display was not so large as then, and this may be due to two causes—mistrust in the weather, encouraged by recent experience; and to the near approach of Eastertide. Yet the show was a very pretty one, and the Hall was fairly well furnished with exhibits, notwithstanding that the work which devolved upon the various committees was unusually light. The Fruit and Vegetable Committee, for instance, made one Award only, and this to a variety of Pear named Winter Orange. Those who have not already cultivated this Pear are recommended to try it, as the fruits will stew well.

The Floral Committee had many very charming groups to inspect, some of which illustrated the beauty of choice varieties of flowering trees and shrubs; the extraordinary floral wealth of the Azaleas mollis and sinensis; the delicious perfume of the Canterbury and other Roses; the remarkable attractiveness of the Boronias when well cultivated; and lastly, the diversity obtainable in well-known species of Ferns. The Floral Committee recommended a First-class Certificate to Erica propendens, and an Award of Merit to Azaleas mollis × sinensis "Betsy de Bruin."

Messrs. Sander's perennial exhibit of the new Acalyphas, hispida, and Godseffiana, was conspicuous on this occasion.

The Narcissus Committee recommended the Award of a First-class Certificate to a fine Trumpet Daffodil named King Alfred.

In the afternoon the Rev. Professor Henslow delivered a lecture upon some of the interesting plants at the exhibition.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. Owen Thomas, H. B May, R. Dean, J. H. Fitt, Wm. Howe, C. J. Salter, Geo. Gordon, E. H. Jenkins, J. D. Pawle, C. R. Fielder, Chas. E. Shea, J. W. Barr, Herbert J. Cutbush, Edwin Beckett, E. T. Cook, H. J. Jones, Harry Turner, R. Wilson Ker, George Paul, John Jennings and H. Selfe-Leonard.

A very charming display of spring flowering species of trees and shrubs in pots was made by Messrs. W. Paul & Son, Waltham Cross Nurseries, Herts. Single and double flowered varieties of the Peach, from palest pink to deepest rose colour, gave colour to the group, and freely-flowered plants of Cytisus præcox (purgans × albus) with its creamy wreaths, Prunus sinensis, fl. pl., Pyrus floribunda Scheideckeri, and others, were equally attractive, as was the doubled-flowered French Cherry, with beautiful white globular flowers. Choisya ternata, Cerasus Fortunei, Deutzia parviflora, Exochorda grandiflora were also noticed among these very valuable plants for pleasure-ground ornamentation. The purity of the flowers of Magnolia stellata contrasted greatly with the rich and warm colours of several new varieties of the Canna (Silver Flora Medal).

A mass of the most delicate shade of pink colour was presented by an exhibit of Cerasus pseudo-cerasus from Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea. About a score of these plants in pots were very pretty. The flowers are double or semi-double, about 1½ inch across, opening deep pink, and fading to white. Messrs. Veitch & Sons also showed a few abundantly-flowered plants of the feathery-white Chionanthus virginicus, Loropetalum chinense, and a pretty variety of Azalea mollis named albicans. Also some very pretty plants of Hippeastrum, the best being Adrastes, Phelma, Runcina, and Hecla. A seedling plant was shown with seven strong spikes and thirty-nine flowers and buds (cultural commendation). Some well-flowered plants of Dimorphotheca Eckloni were noticed.

FERNS.

Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, showed a group upon the floor, composed of Blechnums and Lomarias, there being as many as forty forms represented. The individual plants were splendidly cultivated ones, and the group served to illustrate the characteristics of the varieties. L. gibba was represented by a fine plant, and a specimen of L. attenuata that had made a little stem was very pretty. Beside the more decorative varieties, the group included the diminutive L. alpina, and the New Zealand species, L. fluviatilis (Silver-gilt Banksian Medal).

Ferns were again shown in considerable quantity by Messrs. J. Hill & Son, Lower Edmonton. Some of the Gymnogrammas, as G. peruviana, silver-coloured; G. chrysophylla, and G. argyrophylla, were conspicuous. Asplenium Hilli and A. Belangeri are both useful Ferns. Pteris Wimsetti was present in a large plant, and the distinct P. palmata as smaller examples. Doodia cordata, Nephrodium lepidum, Cyathea insignis, and many choice varieties of Adiantum.

AZALEAS.

Messrs. R. & G. Cuthbert, of Southgate, Middlesex, again contributed the gayest group in the show. These Azalea mollis and sinensis hybrids are wonderful in the variety of colour-tints they afford, and fortunately they possess the characteristics of all Azaleas, viz., that of an abundantly free-flowering habit. The deepest coloured one shown on Tuesday last was a variety of A. mollis named Alphonse Lavallée, a warm red variety with shades of orange, that is an undoubted favourite. A. mollis × sinensis Hortulanus Witte is a very distinct variety, with yellow flowers. J. J. de Vink, Emilie Liebig, Madame Anthony Koster, Geo. Cuthbert, Hugo Koster, Dr. Reichenbach, &c., all show the markings upon the upper petal conspicuously. W. E. Gladstone is a magnificent variety, with warm orange-yellow flowers in grand trusses—a capital companion for the very popular Anthony Koster (Silver Banksian Medal).

ROSES.

Mr. Mount's Roses, from Canterbury, included magnificent blooms of Mrs Sharman Crawford, Catherine Mermet, Captain Hayward, Anna Olivier, Bridesmaid, The Bride, and many others, both as blooms upon the ordinary exhibition stands, and as glorious sprays clad with the healthiest of summer-like foliage (Silver Flora Medal).

Mr. W. Rumsey, Joynings Road Nurseries, Waltham Cross, made a very large exhibit of Roses, that included a large number of varieties. For the present date of the season these were very good. The variety Mrs. Rumsey evidently forces with satisfactory results (Silver Banksian Medal).

A pretty white-flowered Polyantha Rose named Thalia was shown by Messrs. Frank Cant & Co., Braiswick Nursery, Colchester. This perfectly pure-white Polyantha Rose will be much prized, the sprays being charming when cut. Messrs. Frank Cant & Co. had also about four dozen blooms of Roses in variety, all of them very fine in colour.

MISCELLANEOUS.

Boronia heterophylla, B. serrulata, and B. megastigma were shown by Messrs. W. Balchin & Sons, Hassocks Nurseries, Hassocks, Sussex. This extraordinary group of plants, of varieties usually rather difficult of cultivation in gardens, was a great source of attraction. B. serrulata especially, was magnificent, perhaps finer than we have hitherto observed them—even from Hassocks (Silver Flora Medal).

Mr. Jno. Russell, Richmond Nurseries, Surrey, showed about a dozen plants of Dracæna Russelli, a narrow-leaved variety with dull red recurving foliage.

From Mr. John Russell, were also shown plants of Viburnum macrocephalum, a variety with large trusses of white flowers, that somewhat resemble those of Hydrangea Hortensia. It is one of the best Viburnums.

An unusual exhibit from amateurs was that of a collection of hardy and alpine plants shown by Purnell Parnell, Esq., Woodlands, Streatham. A few Primulas, including P. denticulata, P. verticillata were in flower, and the blue Primroses, Irises Persica, &c., but there were also numerous Sempervivums, &c. (Silver Flora Medal).

Cliveias were shown by Messrs. B. S. Williams & Son, Upper Holloway, London, N. Some very large plants were included in this exhibit, and the best varieties were Marie Reimer, Surprise, Prince of Orange, and Scarlet Gem (Vote of Thanks).

AWARDS.

Azalea mollis × sinensis Betsy de Bruin.—An orange-yellow flowered variety, the upper petal marked with red or crimson. The blooms are of moderate size, and form a nice, compact truss (Award of Merit), from Messrs. R. & G. Cuthbert, Southgate.

Erica propendens.—A species of Heath that has been in cultivation for a number of years, and was figured in *Bot. Mag.*, t. 2140, from specimens cultivated in the nurseries of Messrs. Loddiges & Sons. The flowers are rather small, terminal, pendent, and umbellate. In colour, a shade of mauve-pink, though they have been described as purple, or deep red. The leaves are very short, ciliate, and are produced four in a whorl. The plant rarely exceeds 1 foot in height. Those shown by Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea, were exceptionally well-flowered, and were greatly admired (First-class Certificate).

Narcissus Committee.

Present: Revs. E. S. Bourne (Chairman), G. H. Engleheart, Messrs. C. R. Scrase-Dickens (Secretary), J. Walker, A. Kingsmill, R. Sydenham, P. R. Barr, Miss Willmott, and others.

Scarcely any flowers from the open ground were in evidence, the past week's severe weather having emphasized the general backwardness of the spring as regards Narcissi.

Mr. R. O. Backhouse, Sutton Court, Hereford, received the committee's thanks for an interesting hybrid between N. cyclamineus and N. obvallaris.

The Rev. G. H. Engleheart was thanked for a gathering of good hardy hybrids between N. Tazetta and N. poeticus, and also showed some attractive seedling Trumpets.

Messrs. Barr & Sons were awarded a Silver Flora Medal for an exceedingly fine group of pot-Narcissi, the plants dwarf and profusely flowered, notably the new Ajax Victoria.

Messrs. T. S. Ware received a Vote of Thanks for a small stand of Narcissi in pots.

AWARDS.

Narcissus King Alfred.—A remarkably fine Ajax was sent from Mr. Kendall, Newton Poppleford, Ottery St. Mary, Devon. This flower, named King Alfred, appears to be the outcome of a cross between N. Emperor and maximus. The large bloom of rich uniform gold, and thick substance, recalls the features of both parents, as do the tall stems and stout glaucous foliage (First-class Certificate).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), R. Brooman-White, H. Ballantine, N. C. Cookson, A. H. Smee, J. Gabriel, A. Outram, H. J. Chapman, W. H. Young, F. J. Thorne, E. Hill, W. H. White, J. Jaques, H. T. Pitt, W. H. Protheroe, J. Colman, J. G. Fowler, F. Mason, T. B. Haywood, and S. Courtauld.

Orchids were much fewer than on the last two occasions. Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), staged a pretty group of excellently-grown rare specimens, for which a Silver Banksian Medal was awarded. The group contained Odontoglossum Halli, with sixteen flowers; two grand dark forms of O. triumphans, the new orange-red Epidendrum × xantho-radicans, Cattleya Lawrenceana, with sixteen flowers; C. × Lawre-Mossiæ; Cypripedium Stonei, with a fine spike; C. Rothschildianum, with two spikes of fine flowers, and others.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), staged a small group, including the handsome Odontoglossum × Wilckeanum "Primate," with a noble spike (Cultural Commendation); a singular hybrid of the O. × Andersonianum class, with canary-yellow flowers, named O. × flaveolum; O. × Humeanum fulvidum; varieties of O. × Andersonianum, Epidendrum Wallisii, Dendrobium × splendidissimum grandiflorum, and other Dendrobes; Oncidium sarcodes, &c., the centre being occupied by a splendid plant of the still rare Eulophiella Elisabethæ, with three fine spikes (Bronze Banksian Medal).

Messrs. Hugh Low & Co., Bush Hill Park, staged an effective group, in which were several remarkable varieties of Cattleya Trianæi, two white forms with pink tinge on the lip being exceptionally good. Also in the group were very fine Cypripedium Mastersianum, C. × T. W. Bond, C. × Smithii, C. × Winnianum, C. × Godseffianum, C. × Calypso, Dendrobium × Cheltenhamensis; some very handsome forms of Odontoglossum crispum, &c.

Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. Wm. Murray), showed four plants of his Dendrobium × Cybele, Oakwood var., nobile Burfordiense × Findlayanum, all dissimilar. The nearest of the type was white tipped with rose, and with chocolate purple eye. No. 1 had larger flowers than the type, the white flowers tipped with carmine-rose, the disc and the lip orange with distinct maroon eye. No. 2 was similar, but with the dark eye nearly suppressed; and No. 3 was in colour like the light-coloured original form, but much larger.

De B. Crawshay, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), showed Odontoglossum × Andersonianum splendidly grown, and with three flower-spikes; a very handsome white variety of O. crispum, and O. × mulus, Crawshay's variety, with yellow flowers, heavily blotched with chocolate-brown; the lip nearly white.

Messrs. Linden, l'Horticulture Internationale, Parc Leopold, Brussels, showed Odontoglossum Wilckeanum tigrinum, a very handsomely-marked variety; O. × cirrho-Halli, and Cypripedium × Paulii superbum (Boxalli × Chantini superbum).

T. B. Haywood, Esq., Woodhatch Lodge, Reigate (gr., Mr. Salter), showed several forms of his fine strain of Dendrobium × splendidissimum.

W. Thompson, Esq., Walton Grange, Stone, Stafford (gr., Mr. Stevens), showed Odontoglossum × Wilckeanum Waltonense, a very handsome yellow form, richly blotched with purplish-brown; O. Halli nigrum, with handsome flowers, in which the greater part of the sepals and petals are covered with nearly black markings, the lip being large and white, with but two or three small brown spots.

Frau Ida Brandt, Zurich, sent Cœlogyne Sanderæ, a pretty species of the C. Cumingi class; Phalænopsis Aphrodite, and the rare Oncidium Warscewiczii.

W. C. Walker, Esq., Winchmore Hill (gr., Mr. Geo. Cragg), sent Eriopsis rutidobulbum, with three fine spikes, and a good Cypripedium hirsutissimum.

E. de Q. Quincey, Esq., Chislehurst (gr., Mr. G. B. Lees), showed a fine form of Cattleya Trianæi.

Thos. Statter, Esq., Whitefield, Manchester (gr., Mr. Johnson), showed Cypripedium insigne Statteræ, one of the finest of the C. i. Sanderæ class, with rich dark yellow, unspotted flowers, with fine white upper portion to the dorsal sepal, the darkest of the yellow C. insigne.

Sir Wm. Marriott, Down House, Blandford (gr., Mr. Denny), showed a handsome form of Lælio-Cattleya × Latona.

AWARDS.

Lælio-Cattleya × Myra Etoile d'Or (C. Trianæi var. × L. flava), from M. Jules Hye Leysen, Ghent (gr., Mr. Coen), a very handsome clear yellow flower, of similar habit and general appearance to L.-C. × Ernesti "Princess Olga," illustrated in the present volume of the *Gardeners' Chronicle*, p. 149 (First-class Certificate).

Odontoglossum × *excellens var. nobilior*, from M. Jules Hye Leysen, Ghent. A fine form, with bright yellow flowers, handsomely blotched with red-brown. Lip white, with yellow crest, and some red-brown spots. The spike bore fourteen fine flowers (Award of Merit).

Cattleya Trianæi Amesiana, from Messrs. Hugh Low & Co., Bush Hill Park. A very beautiful pure white variety, the broad labellum being of a clear rose-pink in the front portion (Award of Merit).

Dendrobium × *Euterpe* (Nobile × Wardianum) from Sir Trevor Lawrence, Bart. Flowers of the same white and rose-purple shades as D. Wardianum, but changed in form in the direction of D. nobile. The finely-grown plant bore a flowering growth between three and four feet in height (Award of Merit).

Dendrobium canaliculatum from J. Sparkes, Esq., Heathside, Ewhurst (gr., Mr. Smith). A fine plant with three spikes of white and rose-coloured flowers was shown (Botanical Certificate).

Fruit and Vegetable Committee.

Present: Philip Crowley, Esq. (Chairman); and Messrs. W. Wilks, Jos. Cheal, Jas. H. Veitch, A. F. Barron, A. H. Pearson, Alex. Dean, S. Mortimer, J. W. Bates, Geo. Wythes, H. Balderson, F. Q. Lane, Jas. Smith, J. Willard, and Robt. Fife.

Messrs. Walker Bros., 36, Basinghall Street, E.C., showed a few black Grapes that had been imported from S. Africa. These were satisfactory, though not perfectly ripe.

A seedling Apple named Drought's Favourite was shown by Messrs. R. Hartland & Son, Lough Nurseries, Cork. It may be a good Apple, but was a little past its best. Mr. A. J. Thomas, Rodmersham, Sittingbourne, showed an Apple named Diamond Jubilee.

From the Royal Horticultural Society's Gardens at Chiswick were shown twenty-eight varieties of Onions, six or eight bulbs of each. Mr. Wright reported that such bulbs that had not been transplanted kept only until the end of February. Those shown were nice firm, but small bulbs, that would seemingly keep for some time to come.

AWARDS.

Pear Winter Orange.—The stewing Pear, Winter Orange, was again shown by Mr. R. C. Notcutt, Woodbridge, Suffolk. It has been grown in certain localities for a number of years, but at the same time is not generally known. It is of medium size, short, and but little pyriform in shape. The eye is an open one, and is situate in a shallow basin. The variety is a first-class stewing Pear (Award of Merit).

TORQUAY & DISTRICT GARDENERS' ASSOCIATION.

March 22.—Individual competitors were not so numerous as could be wished, and the competition in the open classes was therefore somewhat restricted; but there was no lack of merit. Table decorations again formed an attractive feature, but, as usual, the awards did not give undivided satisfaction.

Azaleas seemed to be everywhere, all covered with bloom. Narcissi, Cyclamens, Tulips, Cinerarias, Hyacinths, Freesias, Primulas, Carnations, were all splendidly represented. A novelty for spring shows were the fine collections of vegetables, New Potatos, Runner Beans, and such like. Among the honorary exhibitors, Mr. J. Snelgrove, was again to the front with a charming collection of plants and blooms. Flowering shrubs at the back towered over rare Orchids, and all the striking colours of the many spring flowers. Miss Lavers, in addition to Orchids, sent a number of Apples and Pears. Curtis, Sanford & Co. had Roses on their stand from the Devon Rosary; W. B. Smale's collection was hardly so striking as usual, but it included a wide variety of choice spring blooms. From Messrs. Veitch, of Exeter, came the usual artistic display, including many of the latest novelties; Burridge & Son, W. Allward, Horn & Sons, T. S. Ware of Tottenham, and J. Heath (Violets and Polyanthus) added much to the attractiveness of the exhibition by their displays. Mrs. Wilson had an interesting exhibit in the shape of Papyrus antiquorum. Included in the South Devon fruit-farm collection were Daffodils, New Violets, and Roses grown under Vines. *Western Morning News.*

MANCHESTER AND NORTH OF ENGLAND ORCHID.

March 23.—On the occasion of the meeting held at the Manchester Coal Exchange on the above date, there were present Messrs. G. Shorland Ball (in the chair), G. W. Law-Schofield, John Leemann, J. Cypher, R. Johnson, and T. Mills (Hon. Sec.).

G. Shorland Ball, Esq., Wilmslow, showed Dendrobium rubens var. grandiflorum (First-class Certificate), D. nobile Amesiæ (First-class Certificate), D. Schneiderianum (First-class Certificate), D. splendidissimum Leeanum (Award of Merit), D. Sybil (First-class Certificate), D. Juno (First-class Certificate), Cœlogyne cristata alba (First-class Certificate), and Odontoglossum crispum (Award of Merit).

Thos. Statter, Esq., Whitefield, showed Dendrobium splendidissimum illustre (First-class Certificate), D. s., Thompson's var. (First-class Certificate), D. s. Leeanum (Award of Merit), D. Rolfe (Award of Merit), D. Apollo, D. Sybil (First-class Certificate), D. nobile Storei, D. Juno (First-class Certificate), D. Clio (First-class Certificate), D. Venus, and Cypripedium insigne Luciana (First-class Certificate).

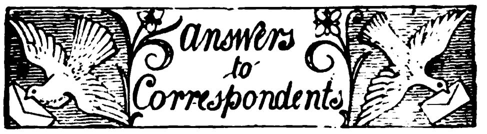
John Leemann, Esq., West Bank House, Heaton Mersey, showed Odontoglossum Andersonianum, O. crispum Mrs. John Leemann (Award of Merit), Cattleya Trianæi var. delicata (Award of Merit), C. Louis Chaton, Dendrobium nobile Amesiæ (First-class Certificate), D. Ainsworthi intertextum, D. Apollo, Cypripedium Germinyanum violaceum, and C. Dayanum; also a group, for which he was awarded a Silver Medal.

D. P. Rappart, Esq., Liscard, showed Dendrobium Venus selwoodense (First-class Certificate).

Messrs. Linden & Co., Brussels, showed Odontoglossum intermedium Queen Victoria (Award of Merit), O. cirrosum Halli (Award of Merit), Mesospinidium vulcanicum grandiflorum, Odontoglossum sceptrum superbum, O. luteo-purpureum splendens (Award of Merit), O. Wilckeanum tigrinum (First-class Certificate), O. hybridum Golden Queen (Award of Merit), O. Ruckeri tigrinum (First-class Certificate), O. Andersoni picturatum (Award of Merit).

Obituary.

Geo. Buchanan Wollaston.—On the 26th inst., at Bishops Well, Chislehurst, the death of Mr. George Buchanan Wollaston has deprived the lovers of British Ferns of one of the few remaining specialists who have done so much by assiduous hunting and careful study to form the grand collections now existing. For some time his advanced age (eighty-four) and failing health have removed him from among the active members of the cult, but his work in the past has stamped him as first among the connoisseurs and standard authorities, while his special finds among the shield Ferns have immortalised his memory. Nor did Ferns alone obtain his interest, for his garden was a marvellous museum of varietal forms of trees, shrubs, flowers, and even weeds. His generosity and kindliness endeared him to all who knew him.



Answers to Correspondents

Cattleyas and Dendrobiums Resting: *Veritas.* A simple method of telling when the resting season has arrived in the ordinary course, is to note when the last growth of all the plants of a species is completed, and no more young growth is coming from the base. Dendrobiums comprise both evergreen and deciduous species, the last-named giving an additional indication that the resting season has arrived by the withering of their leaves. Such species requires a perfectly dry and cool resting season. The Cattleyas and evergreen Dendrobiums, when at rest, also require a lower temperature than when growing, and a considerably reduced supply of water to the roots.

Cœlogyne cristata: *A Subscriber.* The shrivelling of the bulbs seems to indicate that the plant has lately been given an insufficient supply of water at the roots. From now onward, until the new growths are completed, a very liberal supply of rain-water should be given. Indeed, if in well-drained pot, it is scarcely possible to give too much.

Cucumbers Deformed, and Brown in Colour: *Two Blades.* The plants are probably a prey to eelworms at the roots, introduced with the soil. This is always to be feared where it is not the practice to keep loam, &c., in neat stacks with sides smooth, and kept free from all herbage for two years. Can you not send specimens of roots?

Donations.—F. Gibson, 3*s.*; and W. Gibbins, 1*s.* 6*d.*, sent in postal orders for insertion of Gardening Appointments. These sums have been forwarded to the Secretary of the Royal Gardeners' Orphan Fund, as we make no charge for these notices.

Names of Fruits: *J. Phillips.* Apple: Coe's Golden Drop.—*J. E.* 1, Bramley's Seedling; 2, not known; 3, Lane's Prince Albert; 4, Besspool?; 5, Redwinter Reinette; 6, Minchall Crab.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—J. H. Wilkes.* The Ivy is Emerald Gem, so far as can be ascertained from leaves only.—*J. D. Stow.* The raceme of flowers is Epidendrum Stamfordianum; the other small flower, so far as we can judge in its imperfect state, and without the pollinia, is Maxillaria crassifolia. The flowers are produced singly on the stems, but with several rising from the base of the growth. A portion of the growth and fresh flowers would render identification more certain.—*W. T.* Leucoium vernum.—*A. M.* 1, Leucostegia (Davallia immersa); 2, Davallia Tyermani; 3, Sanchezia nobilis; 4, Hoffmannia Ghiesbrechti; 5, Acalypha marginata; 6, Pellionea pulchra.—*J. Barnett.* Ornithogalum (Allium) neapolitanum.—*J. M. Lenton.* 1, Abutilon Sellowianum marmoratum; 2, Abutilon Darwini variegatum; 3, Saxifraga sarmentosa; 4, Nephrolepis tuberosa; 5, Selaginella Wildenovii; 6, Carex variegata.—*E. W.* A very fine Odontoglossum triumphans, both in form and colour. —*W. M.* The cut leaf is known in gardens as Aralia filicifolia; the other as Aralia Guilfoylei. The Camellia resembles "Marchioness of Exeter." *A. E. M.* The Fern seems to be the variety we figured as Adiantum t. Farleyense var. alcicorne; 2, Oplismenus Burmanii variegatus; 3, Begonia Ingrami. The Palm with flower is Chamærops humilis; 6, Dracæna, but impossible to say which from the specimen sent.

Orchid Leaves, Unhealthy: *Pest.* The surface is covered with a whitish mould, which you may destroy by using flowers-of-sulphur in a dry state, or sulphide of potassium, at the rate of half-an-ounce dissolved in 1 gallon of rain-water. Your method of cultivation leaves apparently something be desired.

Pinching the Points of the Side-shoots of Young Vines: *Killiecrankie.* The laterals that are intended to form the future fruiting-spurs, which should occur on the rods at 1¼ to 1½ foot apart, all others being rubbed off early, should be stopped at a distance from the rod of 1½ to 2 feet, accordingly as the space between the rods is small or great. If the laterals at the upper extremity of a cane are stronger than the rest, begin with these, and do not stop the leading point of the rod—at least not till growth is getting to an end. Having stopped a lateral once, stop the resulting shoot at one bud from the point of origin, and so on as long as growth continues, a moderate number of fully-developed leaves being of greater value than many small ones; moreover, crowding is averted.

Rose: *A. E. M.* The centre of the Rose has grown out as a shoot. It is not uncommon, and is due to something stimulating growth at a time when normally it should be at rest. Why it should have done so we cannot tell. It is not likely to repeat the performance.

Violets in Frames: *C. Brown.* We thank you for the kind expression of feeling towards us. The blooms were very fine indeed, and we still hope that when you can find the time to do so, you will describe your methods, which could not fail to be of use to the younger members of the craft.

Wireworms in Vine and Peach Borders: *Anxious.* To "clear" the borders is probably beyond possibility without inflicting injury on the plants, and perhaps killing them. They were, doubtless, introduced with the loam, and being feeders on the roots of grasses and herbage generally, there is the likelihood of their dying of starvation if no plants are grown on the border, and weeds are exterminated. You might take advantage of their liking for the roots of Lettuces, and try to trap them by sowing or planting a number of rows, pulling up the plants intact when ready for use, and burning the roots and soil attached. The Mustard plant, when sown on land infested with wireworm, is said to drive them away. Try it, for it will not impoverish the ground, and may do good.

THE
Gardeners' Chronicle
No. 641.—SATURDAY, APRIL 8, 1899.

CROSS-BREEDING.

A PAPER by Messrs. Walter T. Swingle and Herbert J. Webber, on "Hybrids and their Utilisation in Plant Breeding," *Year-book of the Department of Agriculture for* 1897 (U.S.A.), furnishes a general summary of observations on the peculiarities of hybrid plants, and gives important suggestions for taking practical advantages of them.

After alluding to the fact that in consequence of the great diversity of climates and soils in the United States, numerous varieties suitable to each, respectively, must be raised, since a good vegetable or fruit in Florida may be quite unsuited for cultivation at New York—and in some degree the same rule would apply to the British Isles; the authors proceed to discuss what plants can be hybridised or crossed. Nothing but general rules can be at present held, as there is an extraordinary amount of "capriciousness," so to say, in plants, so that one can never foresee what plants can be hybridised, and what will refuse to be crossed with any advantage.

The first rule is, that the less there is of affinity the less chance there is of crossing, and by affinity is meant the points of agreement between two plants taken in their totality, so that the degree of probability of union decreases from races and varieties to species, genera and families, or natural orders.

As examples of capriciousness, it may be observed that while naturally self-fertilising plants produce a far greater abundance of seed in the wild state than plants with flowers especially adapted for inter-crossing, it may happen that a species is self-impotent, but quite fertile with another and nearly related species.

Again, though the species of the same genus can generally be hybridised, some refuse to be crossed. Thus, Nicotiana acuminata could not be crossed with any one of eight other species (Gaertner). Again, reciprocal crosses can generally be made; but while Mirabilis Jalapa × M. longifolia was fertile, the reverse cross proved to be sterile. Even very closely-related species may sometimes refuse absolutely to be crossed. Thus was it with Cucurbita Pepo and C. maxima (Bailey and Pammel).

On the contrary, Mr. Burbank raised a successful bigener between the Strawberry and Raspberry.

Of different families, Gladiolus blandus was crossed with a Hippeastrum, and yielded four plants; and Digitalis ambigua × a Gloxinia, bore several seeds.

As a practical result from usually self-sterile seedless plants, the fact may be mentioned that they often prove to be fertile when pollinated by other species; as in the case with some seedless Oranges, Pine-apples [Passion-flowers], &c.

Sterility may not be without its advantages, for besides giving rise to seedless fruits, the vegetative system may be greatly enhanced in various ways: in some, as Walnuts, supplying valuable timber; in others, useful herbage; or again, as stocks for grafting.

The characters of the hybrid are usually intermediate between those of the parents; but it is never absolutely so, as all degrees may appear between the one parent and the other. Thus, of Datura Metel × D. Meteloides, of the second generation, there were forty-two plants, of which twelve resembled the mother, two the father, and twenty-eight were intermediate in various degrees.

If the progeny resemble one or other of the parents very closely, or (to all appearances) entirely, they have been called "false hybrids." This was what M. Millardet found with regard to the results of crossing the European Strawberry, Fragaria vesca, with the American species. Some account of his experiments have already been given in the *Gardeners' Chronicle* (Nov. 10, 1894, p. 568).

A great difference exists between the first and later generations of hybrids, the rule being that second and subsequent ones are far more variable, and "the variability is the greater the more completely it was wanting in the first generation;" *i.e.*, the result of crossing more or less widely distant species.

The authors classify under six headings various hybrids according to their degrees of intermediate features as well as sterility, in the first generation and in others, concluding with "false hybrids."

They then discuss atavistic and new characters exhibited by hybrids. They mention a striking instance recorded by Saunders, who says:—"In a cross between Red Fife, male, and an Indian Wheat known as Spiti Valley, female, both beardless, several distinctly bearded sorts were produced in the second generation." As ancient Wheats, as the Egyptian, are bearded, such a result as the above appears to be an atavistic or reversionary character. With regard to new characters appearing, they give photographic illustrations of the two parents and the hybrid offspring of Raspberry × Blackberry. In none are the leaflets dissected, but a leaf of a subsequent hybrid illustrated is supra-decompound. Ten photographs of the canes of a second generation of the same give as many differences.

One section is devoted to graft hybrids, in which the following case is mentioned, besides the Rosa Devoniensis grafted on a Banksian Rose, described in *An. and Pl.*, &c., i. 396; *Gardeners' Chronicle*, July 21, 1860, p. 672. Flower-shoots of the tender Kohl-rabi were grafted on a hardy Cabbage. The seeds resulting from self-fertilisation yielded plants which had swollen stems useful for forage, were very hardy, and yielded from four to five times as much fodder as other sorts of Cabbages able to stand the same degree of cold. This result is very suggestive, and it is to be hoped more experiments will be tried in this direction.

With regard to some special features obtained by hybridisation, the authors observe that it often happens that the progeny of very different species are unusually vigorous. Mr. Burbidge records this fact with regard to Mr. Dominy's hybrid and bigeneric Orchids compared with the parent plants. As other examples, Burbank's hybrid between the English Walnut, Juglans regia, and J. californica, may be mentioned. "It possesses extraordinary vigour of growth, which may render it of exceptional value as a lumber and ornamental tree, the leaves being from two feet to a full yard in length. The wood is very compact, with a lustrous silky grain, taking a beautiful polish; the annual layers of growth being an inch or more in thickness, the effect is unique."

The Raspberry-blackberry hybrid, "Princess," produced by crossing the Western Dewberry (Rubus ursinus) with the Siberian Raspberry (R. cratægifolius) is also an interesting case. Burbank says of it:—"It is remarkable that the hybrid should ripen its fruit several weeks before either of its parents, and excel them much in productiveness and size of fruit, though retaining the general appearance and combined flavours of both."

The authors finally discuss the benefits of crossing in producing increased vigour and fertility as well as hardier sorts, and sorts suited for the warmer climates of the southern States. With reference to the last, they mention the result of crossing the Chinese Sand Pear (Pyrus sinensis) with the European Pear. "This cross has revolutionised Pear culture in the southern part of the U. S., having extended the range of profitable commercial Pears growing hundreds of miles southward. From Virginia and southward to the Orange region of Florida, these two varieties (the Kieffer and Le Conte) have monopolised the Pear-growers' attention; in fact, they have made the Southern Pear culture."

The paper concludes with remarks on breeding better stocks. Hybrids of unusual vigour, even though absolutely sterile, may prove of great value for stocks if they are capable of being propagated vegetatively, as for example, has proved to be successful with Vines on the Continent. *George Henslow.*

EUCALYPTI.

I HAVE been much interested in the many useful articles which are at the present season appearing in your columns relating to these most important trees. From a residence of some years in the Transvaal, where it is being extensively planted, I have had opportunities of observing its suitability as an exotic timber-tree there, and with your permission, perhaps a short statement of the results of these observations may not be unacceptable to your readers. Soon after the Boer occupation of the Transvaal, it would appear that they began to plant a few of these trees around their homesteads, no doubt their extreme rapidity of growth being the recommendation; the consequence has been, that now that gold-mining is the staple industry of the country, and as there is a great want of timber for mining purposes, many companies have turned their attention to tree-planting in order to supply this want, the result has been that pretty extensive plantations have been made in the neighbourhood of the great mining companies. Several of the principal of these plantations, in the neighbourhood of Johannesburg and Pretoria, I have had the privilege of examining. The "Bruamfontein Plantation," extending to about 1000 acres, also "Orange Grove," and "Boysum," all planted within the last twelve years, are to the eye of an English arborist marvels of success. Although only planted during the time stated, when I visited them two and a half years ago, the trees ran from 15 to 40 feet high, the older portions supplying good pit wood, girthing from 12 to 18 inches, and from 20 to 25 feet long; these were merely thinnings.

The predominant species planted was E. Globulus, the Blue-gum; E. viminalis, resinifera, robusta, and diversicolor have also been tried. However, the two varieties which appear to do best are Globulus and viminalis, each attaining great size in a few years. For hardiness I think viminalis is preferable, and from information I received its timber is tougher and more durable. The very limited experience on this point, however, may be misleading, as every one knows, though elasticity and durability of timber depends a very great deal upon the soil in which it is grown, the same variety grown under different conditions as to soil and situation may give very different results; one thing I specially observed, however, was that viminalis seemed to be much hardier than Globulus. In the winter of 1894 we had frequently from 15° to 20° of frost, the young shoots of Globulus were pretty severely cut, while viminalis growing beside it was not touched; robusta also appeared to enjoy immunity. The plantations referred to are all situated on elevations, varying from 4500 to 6000 feet above sea-level, and the temperature in winter is often as low as 10° F. The soil is generally a red loam, rather poor, very much impregnated with iron, except along the banks of streams and vlais or damp hollows, where the soil is darker and more alluvial; the whole, however, is more or less ferruginous, such being apparently thoroughly suited to the Eucalyptus. As an example of the enormous growth of this genus in the Transvaal, I may mention that on visiting Linhaard's Vlai, about 20 miles west of Johannesburg, my attention was drawn by the manager of the estate, Mr. Forbes, to a row of Eucalyptus on the boundary of the homestead, which he reported as being from 20 to 25 years old. I roughly measured two of the largest; one was 15 feet in circumference 5 feet from the ground, with a clear stem of about 55 feet without a branch; the full height of the tree would be about 80 feet; the other was 13 feet in girth, with a similar stem and height. Both seemed to be E. Globulus, but from the height of the branches it was difficult to identify them.

From these observations I hold a very strong opinion that the hardier varieties such as I have indicated might be planted with excellent results in several situations in the British Isles, such as in the south-west of England and the south and west of Ireland; and even in certain parts of the west of Scotland, I believe, gratifying results might be attained. One thing, however, must be kept in view—that they should not be planted in low sheltered localities, where they would be long in ripening the young shoots, or where there is a liability to hoar frosts. Comparatively high and exposed situations should always be selected. Again, I am convinced that they should not be used in mixed plantations, because by their rapidity of growth they would early overtop any other variety, and be therefore exposed to high winds, which would destroy the young upper shoots.

Before closing, I may just say that there are other trees grown in South Africa which I have an idea might be with advantage tried in certain situations in this country. I refer to two or three varieties of the Acacia, viz., Acacia dealbata (the Silver Wattle), A. mollisima (Black Wattle), and A. melanoxylon (Black-wood); the timber of each of these are excellent, and the bark of the two first mentioned are most valuable for tanning. In the Transvaal they are quite as hardy as the Eucalyptus, although more slow growing. I hope some one may take this hint, and give them a trial under similar conditions as Eucalyptus.

In a future communication I will give a few notes of my observations on the rearing and planting of Eucalyptus. *Chas. S. France, 7, Belmont Place, Aberdeen.*

SPONTANEOUS HYBRIDS OF HARDY PLANTS.

(Continued from p. 165.)

HYBRIDS of Polemonium are interesting as affording the most complete example of inversion of species I have seen in perennials. Out of about seven kinds which I have grown, five seem quite ready to make hybrids, the exceptions are P. pauciflorum, an annual with a very distinct flower, which I have only once grown, and P. confertum, a most unkind and capricious plant, which I have both obtained from nurseries and raised from seed collected in Colorado, but never can keep for more than a year or two. It has rarely flowered in my garden, but when it has, it has been in March or April, long before any other of the genus was in flower. P. cœruleum, including its variety, miscalled in gardens P. Richardsoni, as well as P. reptans, P. flavum, P. humile, and P. himalayanum, all make hybrids with one another, which are invariably quite barren. The inversion mentioned above is made by P. flavum × P. cœruleum, the seed parent P. flavum, as far as flower and leaves go, exactly reproduces the pollen parent, but the habit is less upright, and the flowering period much prolonged; the white-flowered and the blue-flowered are produced indifferently, and their constitution is very robust, as the plant may be cut to pieces and increased without trouble indefinitely. There is only one other hybrid in the genus, which, as a garden plant, is superior to either parent. This is P. Richardsoni (I write the name under protest, as it is certainly not Graham's plant figured in the *Botanical Magazine*, tab. 2800) × P. humile; this hybrid has the flowers of the seed parent (which is probably a variety of P. cœruleum) and the habit and stature of P. humile. Other hybrids in the genus present intermediate characters, but do not call for special notice.

Phlox has produced here several rather mysterious hybrids, I call them mysterious, because the most distinct has always been labelled in Kew Gardens as P. Stellaria, which it much resembles; however, two trustworthy gardeners have assured me that they raised it independently of one another from seed of P. subulata, before P. Stellaria had ever been in their gardens. I have never seen a seedling from the type P. Stellaria, which I keep with difficulty through wet winters, but this supposed hybrid, which I named G. F. Wilson, makes seedlings sparingly, some of which nearly reproduce the seed-parent; others seem to be crossed with P. amœna, others are nearer the type of P. subulata. Phlox G. F. Wilson has an exact portrait, made seventy years ago, in *Loddiges' Cabinet*, t. 1722, and is called there P. procumbens. The P. procumbens of Sweet's *English Flower Garden*, t. 7—also more than half a century old—is different. Both these portraits are noticed under P. procumbens in Asa Gray's *Flora of North America*. It is there said that they have never been matched by wild plants, and P. procumbens is placed by Asa Gray under P. subulata. This is the only set of hybrids I have ever seen in Phlox.

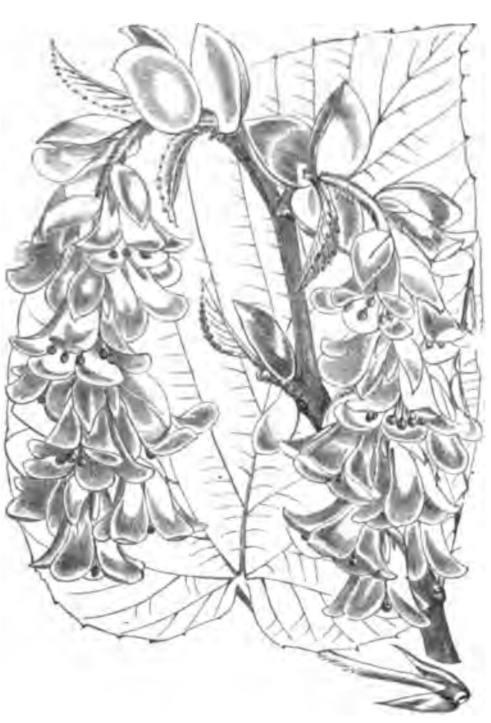

FIG. 79.—CORYLOPSIS SPICATA: COLOUR OF THE FLOWERS PALE YELLOW. (SEE P. 211.)

To speak of spontaneous hybrids of Primula, the European alpines of the Auricula group succeed but moderately out of doors in Edge garden, the wet and changeable winters allow them little rest, and they start into growth too early to escape injury from spring frosts when in flower. A good many are grown in cold frames, and the produce of their seed shows that they cross freely, but these natural hybrids of Alpine Primroses having been made a special study, are mostly well understood by botanists. One thing I can say, that seed saved in these frames either from the wild yellow P. Auricula or the purple P. viscosa, produces a great variety of what are known as "border Auriculas," and these hybrids are fertile and produce an ever-varying race.

The hardy species of Himalayan Primroses are grown out of doors at Edge in abundance. P. rosea and P. denticulata flower simultaneously; but I only once saw a manifest hybrid between them—two or three plants were produced the same season, in which the colour of the flower and the characters were intermediate between the two. The plants were vigorous enough, but were so far from ornamental, that no attempt was made to perpetuate them. Primula scotica and P. farinosa have more than once made neat little hybrids, but they were not persistent, and neither of these species come up here from self-sown seed. *C. Wolley Dod, Malpas, Cheshire.*

(To be continued.)

THE FERNERY.

FERN PROPAGATION BY APOSPORY.

AT the meeting of the Linnean Society on Thursday, February 2, Dr. F. W. Stansfield, of Reading, read an interesting paper on a case of induced apospory in Athyrium filix-fœmina, which should be of interest to cultivators of Ferns. So far, the instances noted have been upon varieties found wild, or which have originated under culture with the aposporous features manifest at once to experienced eyes, but in this particular case of A. f.-f. unco-glomeratum we have a more beautiful Fern, which for many years has shown no sign of the phenomenon, does not present in its fronds those peculiar attenuations which are usually correlated with it, and has only become aposporous after some eighteen months of close culture of detached pieces of the frond.

The whole case is remarkable from the fact that a normally deciduous species, without being subjected to warm treatment at all, was persistently grown for the time named, and that the detached pieces bore no roots, nor formed any until the prothallic stage had been arrived at, the tips remaining perfectly green, and dividing and re-dividing dichotomously in proportion as the basal portions turned brown and died. A. f.-f. unco-glomeratum is a seedling from a remarkably ramose form of the species found wild in Yorkshire, A. f.-f. acrocladon. The fronds of this plant ramify from the base upwards to such an extent as to form a loose ball of moss-like appearance, but this feature is exaggerated in the variety under notice, the division being carried to a greater extent, and usually only ending with the dying down of the fronds in autumn. Dr. Stansfield, however, observed that even then the minute dichotomous tips retained their verdure long after the fronds were down and otherwise dead, and in 1897 he determined to cut off some of these, and layer them to see what they would do. The result was the continuance of growth and division, as stated above, and eventually, when the proper growing season arrived, he was delighted to find that the dichotomous division ceased, and that here and there the ultimate tips were dilating into prothalli, while in addition bulbils began to form here and there, both on the ultimate ramifications and on the prothalli, sexually-produced typical plants resulting as well from the latter. The prothalli bore archegonia and antheridia, as is implied by the last statement, and in one case a typical Fern resulted from a cylindrical process from the under edge of a prothallus, which already bore an apogamous bulbil on its upper surface, and a sexual plant beneath it.

We have here consequently a Fern which is seemingly incapable of closing its circuits of growth by forming terminal cells; the apical cells continue to multiply indefinitely, building up as they proceed the typical form of the variety, until it becomes a question of forming roots or root-hairs, or stopping for sheer lack of nourishment. At this stage, aided by extremely close culture, they find a *modus vivendi* in two ways, viz., by forming bulbils, which develop roots and start new individuals, and by thinning-out their substance and forming prothalli which develop root-hairs, and so obtain a fresh foothold for another generation. Apospory here has clearly been entirely induced by protracted culture, and the result is the propagation for the first time of a quite unique Fern. Stimulated by this success, Dr. Stansfield laid down a number of pieces of various finely-divided Ferns, and reports that within a fortnight after he had done so, incipient prothalli were produced from extensions of the terminal veinules of Polypodium vulgare var. grandiceps, Parker, though unfortunately the culture went wrong and fungi destroyed the piece shortly afterward. This discovery brings, not merely new proof of the possibility of inducing apospory in unexpected quarters, but adds another species to the already swollen lists of aposporous Ferns.

The writer also availed himself of the opportunity of exhibiting a second aposporous Scolopendrium in which the heavy crests are fringed with prothalli all over, in addition to a few produced on lateral projections. The parentage of this Fern is not known, it declared its character in his collection as a seedling last season, and cultures have yielded dense clumps of prothalli which were exhibited in conjunction with the plant itself, though time precluded any observations thereanents.

Clearly with these examples before us, it would be well worth while to extend research to such exotic Ferns whose barrenness stands in the way of propagation, while their finely cut character may indicate the possibility above set forth. Incidentally it is worthy of remark, that apospory proves to be no bar to variation. Hitherto, indeed, in the several revised cases of aposporous plants of Polystichum angulare, the progeny has been defective and depauperate, but Dr. Stansfield has succeeded in raising pure bred typical plants from Moly's unique variegated form; and the writer raised an immensely improved plant of A. f.-f. clarissima, Bolton, so that culture in this direction may well compensate him who takes it in hand, both by enabling him to propagate presumed barren forms, and improve them by selection. *C. T. Druery.*

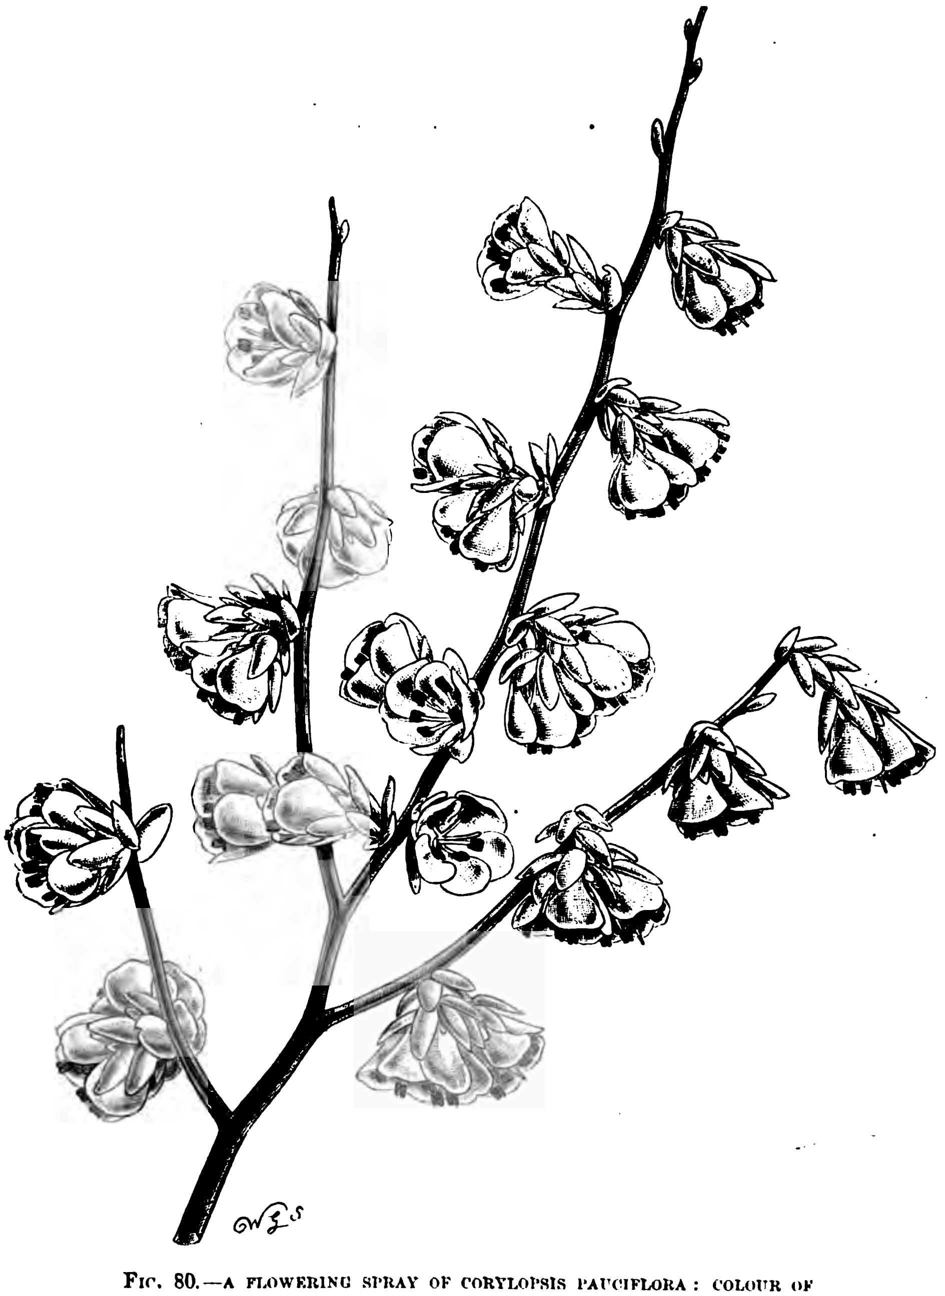

FIG. 80.—A FLOWERING SPRAY OF CORYLOPSIS PAUCIFLORA: COLOUR OF FLOWERS PALE CREAM OR YELLOW.

CORYLOPSIS PAUCIFLORA.*

SPRING-flowering shrubs are always welcome, but the present species, though long known, is by no means familiar to planters or gardeners. We owe the opportunity of figuring it to Messrs. William Paul & Son, of Waltham Cross, who exhibited it at one of the recent meetings of the Royal Horticultural Society. The day was so foggy that the flowers appeared to be white, but in a better light they are seen to be pale primrose-yellow. The shrub is perfectly hardy, the flowers are produced in early spring before the leaves; their general appearance is shown in the illustration (fig. 80). The shrub reminds one in general character of the Hazel, with the leaves of the Hornbeam. Its affinity, however, is with the Witch-Hazels (Hamamelis), also winter-flowering shrubs of much attractiveness, and with the Parrottia, whose leaves assume such glorious golden-bronze and purplish tints in the autumn. Corylopsis spicata (fig. 79) is perhaps better known. It has broader leaves than C. pauciflora, and ten to twelve flowers in the cluster instead of two or three only, as in C. pauciflora. Both species are of the easiest culture. We suggest that small plants might be lifted in the autumn and placed under glass, in order to accelerate the unfolding of the flowers. Probably they would not bear high temperatures. The construction of the flowers is so peculiar as to be of interest to the botanist, independently of their attractive appearance.

AMERICAN NOTES.

WINTER DAMAGE.

THE closing winter has been very hard on many fruits in nearly all sections of North America. Those sections which have suffered least are the Pacific coast fruit-region, upper New England, and the maritime provinces of Canada. The Orange-growing regions of Louisiana and Florida have been severely visited by freezing weather, the crop being wiped out in many districts. The Peach-growing sections of Georgia, Maryland, Delaware, New Jersey, Connecticut, Massachusetts, Michigan, and Ontario, are said to be so badly bitten by the cold as not to promise any fruit for this year's market. (It may be said parenthetically that it is customary in this country to magnify these disasters at this time of the year, though it really seems that the case is serious this time). Apple-trees which appear to be in excellent condition in the Eastern States, have sustained heavy damage in many parts of the Mississippi Valley. Secretary Goodman of the Missouri Horticultural Society says, "there never have been such serious results from any cold winter as this one, during the history of fruit-growing in Missouri." I am reliably informed that many thousands of Apple-trees have been killed in Minnesota, Iowa, Wisconsin, and neighbouring states. In all these sections Peaches, Plums, and other fruits (where grown) have suffered even more severely. This winter will be a final test for many of the much-advertised "ironclad" varieties.

EXTRA HARDY FRUITS.

The destructive winter will doubtless revive interest in the search for extra hardy varieties of fruits. This hunt has been going on in this country with waxing and waning zeal for a quarter of a century or more. No more interesting or instructive piece of horticultural history could be mentioned. Thousands of horticulturists, spread over a territory of 600 miles wide and 2000 miles long, have been striving by every means in their power towards one end. That end is the production or discovery of fruits (especially Apples) which shall withstand the severe winters of Canada and the Northern States. It seems to me that there has never been an experiment in plant breeding and acclimatisation attempted on such a tremendous scale. To a great degree the efforts have been successful, and Apple-culture has moved forward many miles upon the northern frontier in the last two decades. The work still goes on. There is not space here to give any account of it; but a few of its features have been the Russian expeditions of Charles Gibb, Professor Budd, and Professor Hansen; the extensive importations of Ellwanger and Barry, S. D. Willard, A. C. Tuttle, the Department of Agriculture; the intensely interesting breeding experiments of Peter Gideon and others, and especially the fortuitous discovery of hardy native seedlings. The man who would collect the facts could make a good book on this subject, one valuable as history, and valuable to horticulture.

---

* Corylopsis pauciflora, Siebold et Zuccarini, *Flor. Japan*, cent. i. (1835), t. 20.

APPLE CANKER.

It is the opinion in Europe, I feel sure, that American fruit-trees are a badly infested lot. We are always discovering some new insect or fungus-enemy, and we are always talking about them—quite too much, so far as our relations with Europe are concerned. Our Trans-Atlantic friends should bear in mind the fact that we are making a very thoroughly organised study of these things here, and that minute knowledge of such subjects is demanded by all our successful fruit-growers. The latest orchard enemy to come to notice is the "Apple-canker." This is probably not the canker described in England by Forsyth (*Treatise on the Culture and Management of Fruit-trees*, 5th ed., p. 349), yet it is somewhat of the same nature. It has been commendably studied by Mr. W. Paddock, of Geneva, N.Y., who finds it to be caused by the same fungus that causes the black rot of the fruit, viz., Sphæropsis malorum, Peck. It causes the branches to blacken, and the bark to crack, and eventually kills the limb or the whole tree if not overcome. It seems that the disease is quite destructive in some parts of the country. It appears to be of more than usual economic importance, and we are glad to learn that it probably can be controlled by spraying with Bordeaux Mixture, and without altering greatly the plan of treatment now in vogue in all good American orchards. *F. A. W.*

THE ROSARY.

THE PRUNING OF ROSES.

Shivering here in Edinburgh towards the end of March, with from 12° to 20° of frost, and the north winds of March curdling one's breath, it was just a little tantalising to read Mr. Chapman's advice in your "Flower-garden Calendar," to prune Roses a fortnight sooner, as they were so much earlier than usual. Why, north of Tweed, and in large districts south of Tweed, the season has the safety and merit of being late. Even the fruit-buds, to say nothing of the more restful forest-trees and shrubs, are specially restful and dormant; and refused to move at the bidding of the two days or so of June that we had in the early days of March. But then Mr. Chapman wrote from genial Gloucestershire, and since he wrote, the west has also had a taste of an old-fashioned March, which may have robbed the instructions of the earlier pruning of Roses of their urgency. But then local conditions must be studied before beginning to prune. For example, advising as to Woburn, Bedfordshire, before the cold snap of 2° below zero the other week, one might have advocated early pruning. Now, probably, the middle of this month will be better.

The varieties of Roses and their idiosyncrasies must likewise be studied. Long ago we grew comparatively few species of Roses, and most of these, excepting the pink Monthly, flowered but once a year, and might with safety be pruned as soon after the fall of the leaf as convenient. In fact, the summer Roses, Cabbage, Moss, and hardy climbers, were pruned on the heels or abreast of the Gooseberries and Currants. The old Monthly or China Roses could hardly be said to be pruned at all in the modern sense of the phrase. The shoots were slightly protected, covered, or cut back almost level with the ground, and seldom or never failed to give a good account of themselves the current or coming season.

To a considerable extent, rosarians are finding out that what suited the old Chinas also suits modern Teas. The less pruning with many of these the more and the better bloom. Judicious thinning rather than close spurring is what these Roses most need. As to other Roses, modern growers have entirely reversed the old maxim as to hybrid perpetuals and other varieties. The stronger they grow, the harder and closer should they be pruned back or spurred in. The practical result, as proved by years of experience, being the longer the shoots are pruned off, the fewer and less perfect the blooms. Hence, now the clear and simple working rule in pruning is the maxim—the weaker the shoots, the harder they should be pruned; the longer and stronger, the less pruning—and thus it comes to pass that the spurs or Rose-shoots left for bloom may have as wide a range as from an inch to a yard or more. Mr. Chapman gives excellent advice on these points. I was also pleased to note his special paragraph devoted to the Pink Monthlies and other China Roses. I wish also to endorse his views as to the superiority of young Larches from 8 to 15 feet high as supports for pillar, pyramidal, or climbing Roses. These young Larches, if cut in the early spring and pealed in bole and branch, are more ornamental, clean, and lasting, than when the bark is left on. The Roses are more effective when the lower branches are left from 15 inches to a yard wide at the base, and taper into 6 inches or less at the tip, thus forming graceful cones. The resin in the Larch is as efficient as a coat of varnish in shedding off the rain and excluding vapour. In fact, I have found pealed Larch equally or more durable than varnished or tarred sticks or stakes. *D. T. F.*

NOTICES OF BOOKS.

THE PESTS AND BLIGHTS OF THE TEA PLANT, ETC.

By George Watt, M.B. (Calcutta, Government Press, 1898; pp. 467, t. xvii.)

This is an account of a visit paid by the author to the Tea-growing districts of Assam, in order to study the Tea-blights and to inquire into the value of Adhatoda Vasica as an insecticide. The report is professedly of a popular character, but lays down certain general principles for future guidance, and suggests means of co-operation between the planters and scientific investigators. An infusion of the leaves of Adhatoda proved serviceable in the case of red spider and white ants. A decoction of a Fern, Nephrodium aridum of Baker, has also been found an effectual insecticide; but as Dr. Watt points out, until the life history of each pest is fully understood, the application of insecticides is empirical and unsatisfactory. Where the plantations have been well cultivated there are relatively few blights, at the same time cultivation itself induces an unhealthy condition, or at least, a predisposition to disease. The Tea-plant is, as it were, forced to produce a disproportionate amount of foliage, and it is grown under abnormal conditions which predispose the plant to the attacks of disease.

Dr. Watt sketches briefly the physiology of the Tea-plant, and the practical details of cultivation. A good manure for Tea would be composed per cent. of mineral phosphate 50, saltpetre 30, wood ashes 20, potash, lime, nitrogen, phosphorus, all requisites for the growth of Tea being thus provided for.

Various leguminous plants are used for green-manuring. A detailed account of the various pests (insects) and blights (fungi) is given, together with indications as to the best method of coping with them. This portion of the volume is a veritable cyclopædia of information, and is most valuable for purposes of reference. How the unfortunate Tea-plant manages to survive at all is a mystery after the inspection of this formidable list of enemies.

BULLETIN DE LA SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.

We have once more before us the annual publication of this useful and prosperous Society. Having already had occasion to notice it several years in succession, we need only say that the present issue is in style and get up, much the same as usual, although of course the literary matter in the body of the work is quite different. It is interesting to note that, both financially and numerically, considerable advance is being made, and that after ten years' existence, the Society can boast of a total of 500 members, including many of the most famous horticulturists on both sides of the Channel. Leaving aside the ordinary matter relating to the Society pure and simple, it may be worthy of mention that some of the papers read at the meetings of the Society comprised such subjects as the Swanley Horticultural College, Vine growing in Wales, the Leading London Parks, Notes from Annan, besides several others on cultural subjects. The frontispiece this year is a portrait of Mr. John Ouvrard, with a short biographical notice of that gentleman written by Mr. Geo. Schneider, the President of the Society, and to whose efforts so much of its success is due.

WEEDS.

The Canadian journal, *Farming*, as quoted in the *Agricultural Journal of the Cape of Good Hope*, in a recent number, contains a paper on this subject by the Professor of Biology and Entomology which may be interesting, and the study of weeds and weed-seeds as recommended may be found very helpful in fighting these enemies of crops:—

"An authority has stated that weeds have been a blessing to the farmer and gardener.

Very few will care to acknowledge off-hand the truth of this statement, yet when we look into the matter carefully much can be said in its favour. The continuous warfare that every tiller of land must wage in his efforts to control or exterminate the weeds keeps the surface-soil in better condition to withstand drought. The gardener must hoe, the farmer must plough, harrow and hoe, else his foes, the weeds, would soon get the upper hand and strangle the crop.

It is a well-known fact that any loosening of the surface-soil has the effect of conserving the moisture. The study of physics also reveals the fact that water rises in fine tubes or pores above the level of the water outside the tube, and that the smaller or finer the tubes the greater is this difference of level. When a gardener works the soil the pores are made larger, for the particles are made less compact than before, hence the subsoil water does not rise so high, and evaporation is not so rapid.

During seasons of drought this simple act of loosening the soil with a hoe and rake plays a very important part. Weeds compel this simple act, and hence are beneficial in this respect.

On the other hand, weeds, like other plants, require water, which is imbibed by the roots, and carried to the leaves. The great bulk of this water, which has acted as a vehicle for the transportation of salts from the soil to the laboratory of the plant—the leaves—is again transferred, or evaporated into the air, and hence lost to the soil. It can be readily seen how very important is this question of weeds in a dry season, when the subsoil-water requires to be looked after and conserved.

Again, weeds, like other plants, require nourishment, and, when they are allowed to grow, the salts, which should be absorbed by the crop, are taken up by the weeds. This piracy on the part of weeds can be stopped only on the death of the weeds.

Most farmers are able to recognise weeds. They can tell when one plant is interfering with the proper growth of some other plant which is of greater economic importance. A weed has been cleverly defined as a 'plant growing out of place.' Nearly any plant may become a weed, but only a few hundred out of many thousand become weeds of any economic importance. According to the definition given above, weeds would include the lower plants, such as smuts, mildews, rots, and moulds; but, popularly, weeds are looked upon as plants of considerable size, and the microscopic species are not considered.

A knowledge of the habits of weeds is the first essential in a scheme for their eradication. For example, the following habits should be thoroughly studied:—

1. Is the weed an annual, biennial, or perennial? If the weed is annual, destroy it before it seeds.

2. Is its seeding capacity great or small?

3. How are its seeds disseminated or distributed—by wind, water, or by animals? Many a farmer finds his fields full of Thistles through the carelessness of a neighbour, who neglects to cut his Thistles before they seed.

4. Is its root system extensive? The Thistle propagates itself by its extensive root system. The common Bind-weed has an enormous system of roots, which is almost impossible to eradicate. Kill the weed when it is young, before it becomes deeply rooted.

5. Is the weed a parasite? The Dodder fixes itself to the Clover-stem, and imbibes food from it through roots which it sends into the plant. The only remedy in this case is to destroy the Clover crop, and to be extremely careful in the selection of Clover seed.

Farmers must insist on pure seed, if they wish to keep a check on weeds.

A knowledge of weed seeds is nowadays necessary to the successful farmer.

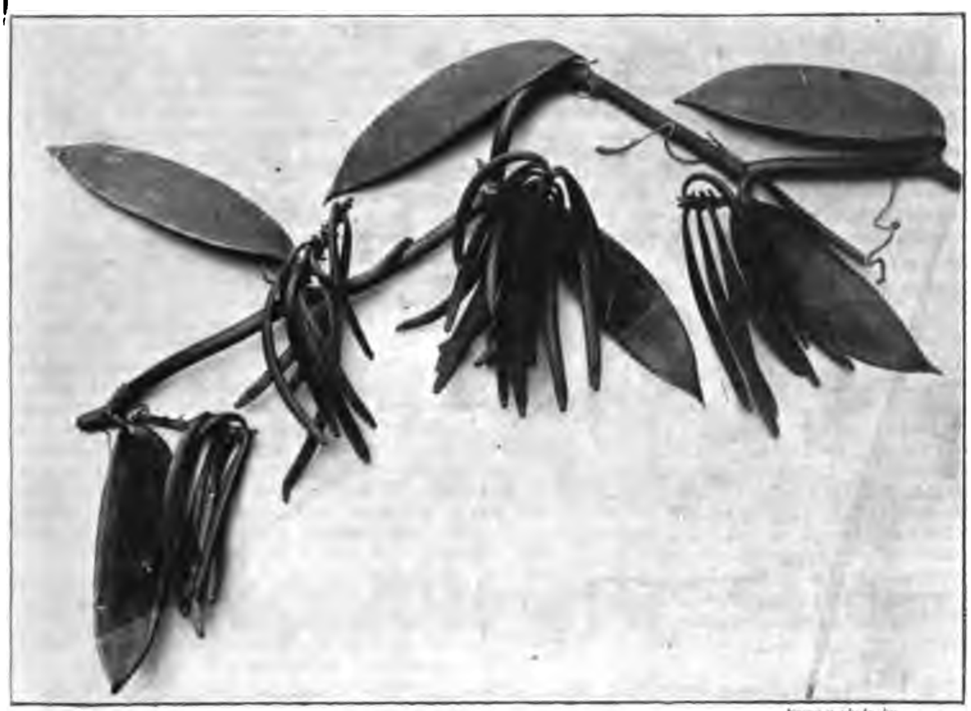
The botanical section of the Experimental Union is now making up sets of weed seeds, which will be distributed in due time to those who are interested in weed eradication.

Experience has shown that the following bad weed seeds are very frequently found in Timothy seed: Ox-eye Daisy, Yarrow, Chamomile, Thistle, and Fox-tail. Clover seed has Heal-all, Dodder, white and yellow Melilot, Pepper-grass, None-such, narrow-leaf Plantain, and Bouncing Bet. These are all most miserable weed seeds, which should be carefully looked after.

Eternal vigilance is the price of freedom from weeds."

VANILLA PLANIFOLIA.

Having this season been fortunate in securing a good crop of the Vanilla-pods, it may interest readers of the *Gardeners' Chronicle* to know our method of procedure. We do not always thus succeed in fruiting the species, though generally the plant produces a fair amount of bloom. In respect to setting the blooms, the instructions given in the *Gardeners' Chronicle*, vol. xxii., p. 307, should be helpful to those who have had but little experience in the matter. I have never known a pod to set naturally, and this shows the need there is to understand the peculiar formation of the flowers. The pollen is so much closed in, that considerable care is necessary to remove it to the stigma. Flowers that have not been artificially pollinated sometimes develop pods, but these fall as soon as half grown, and are useless. In my previous note above referred to, I stated that we had recently planted this Vanilla in a new position, and had given it more exposure. This has yielded us much better results, and though a partial shade is necessary when the plant is in active growth, it is injurious from October until March.



From a photo. by J. Gregory, Croydon.

Fig. 81.—Fruiting spray of Vanilla planifolia.

A total failure one year in the case of plants growing in shade, and of others in comparative light, induced us to plant in another house, where they were more fully exposed, and here we have had splendid results, some of the clusters having over twenty pods, and seven clusters on a single growth. The growths are very strong and healthy. Therefore, though partial shade is necessary during the hottest part of the day, I would condemn the use of one continuously. Though we have bees very close to the house, they do not appear to take the least notice of the plant when in flower; but it must be borne in mind that there are few flowers only open at the same time. They are rather insignificant also, being of a greenish colour, and devoid of aroma. It is important that the shoots be well ripened, and after the end of August I would shade but very little. The leaves under this culture will have less colour. We give a lower temperature in the winter months than is frequently advised. From March to the early part of September moisture is given freely, and the plants throw out thick fleshy roots, which lay hold of the wall or the woodwork with which they come into contact. What is termed a brisk stove-heat is suitable during the growing season, but in the autumn and winter months 60° by day and 55° by night will suffice. The plants should not be syringed during the winter, as if the pods are numerous, the syringing causes them to decay at the ends.

As regards temperature, I do not think a few degrees of heat more or less in the growing season of much importance if there is an ample supply of atmospheric moisture. We syringe three times daily, unless the plants are in flower, when it is best to keep the foliage dry. The Vanilla grows grandly in a Pine-stove if placed in such a position that the stems can get hold of some support upon which to fasten their roots. Having so few roots, only a shallow border is needed. This in our case is not more than 6 inches. The compost should be good fibrous peat, with large lumps of charcoal and clean potsherds. No matter how grown, the plants have a tendency to get naked at the base. We therefore take down each spring some of the best top-growths, and place these at the base, giving some fresh material for them to root into, keeping the house for the time a little closer, and syringing freely. The pods after setting, are only a few weeks before they are of full size, but they remain for seven or eight months on the plants before they begin to colour. This is an advantage, as the plant in a fruiting state is an interesting object. When the fruits are gathered, they should be kept in a drawer or other dry place. They are best kept in an air-tight compartment. When quite ripe, they then keep good for years, retaining their rich aroma. I have not spoken upon pot-culture, as I regard the one described as the most suitable. *Geo. Wythes.*

LODDIGES, AND STEAM-HEATING OF GLASSHOUSES.

We were reminded by the sale recently of the library of the late C. Loddiges, of the famous nursery carried on at Hackney by his progenitors, Conrad Loddiges, and his two sons, which, as was stated in an article on old suburban gardens, in a recent issue of the *Gardeners' Chronicle*, disappeared entirely late in the forties.

Loddiges' was the home of many of the new plants of the latter part of the last and first half of the present century. The glass structures at the Hackney nurseries, at the time probably the most extensive in the country, were, previous to 1816, heated chiefly by smoke flues. In that year, as we learn from a note appended to a description of Passiflora racemosa in the forty-fifth volume of the *Botanical Magazine*, steam was adopted as the heating medium; two boilers, each equal to driving a 20 H.P. engine, and fitted with safety and vacuum-valves, hydrostatic balance, steam-gauge, &c., and containing about 2000 gallons of water each, were erected. One boiler only was used at a time, the other being kept in reserve, in case of repairs being necessary. The steam pressure was low, never more than 225°, Fahr., or 4 lb. per square inch above atmospheric pressure. This was conveyed in cast-iron pipes of 4 inches in diameter into the largest stove, which was 200 feet long and 22 feet high in the centre; this house contained 30,560 cubic feet of air, which was kept in winter from 60° to 110°. From this house the steam was conveyed westward to three other houses, two being greenhouses, and one intermediate, having a total cubical contents of 15,160 feet; and eastward to a greenhouse 180 feet long, which communicated with another 492 feet long, containing together 45,000 cubic feet. These were kept in winter at an average heat of 50°, Fahr. There was altogether half a mile of pipe charged with steam, and the houses warmed to the furthest extent in about twenty minutes, effectually keeping the air under 20,000 square feet of glass without covering to the above temperatures, producing a regular, pleasant and highly advantageous atmosphere for plants, perfectly divested of every sulphurous and scorching quality which the best-regulated furnaces and nicest-constructed flues could never afford. The use of steam, however, made little headway in gardens, and early in the forties hotwater apparatus was taking the place of that and flues as a means of heating glasshouses. From this note in the *Botanical Magazine* it may be inferred that Messrs. Loddiges were among the first, if not the first, nursery firm to make use of steam heating.

THE WEEK'S WORK.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

The Protection of Fruit Blossoms.—The severe weather experienced recently shows the necessity of having protective materials in readiness wherewith to afford shelter to fruit blossom, the week ending March 25 being one of the coldest on record for the season. The previous week or two having been comparatively mild and sunny, Peach and Apricot trees on south walls were in full bloom, and although a few degrees of frost were experienced, the weather being dry, there was not in our district sufficient frost to call for covering being placed over the trees before the morning of the 20th, when several thicknesses of garden netting were suspended over all our trees in bloom. Where wide copings existed this has, I think, saved sufficient bloom to ensure a crop, although 15° of frost were registered on three successive nights, and accompanied by frequent snow-showers. Peach-trees on walls facing the west were somewhat later, and much of the blossom had not expanded; this appears to be uninjured. It is a most noticeable fact that the blossoms in close proximity to the wall have escaped injury, where others projecting an inch or two from it have mostly suffered, and this is a point where trees nailed to the walls in the old way with shreds have the advantage in this respect over those trained to wired walls, which invariably stand further away from the brickwork, and consequently in cold frosty weather are more liable to suffer injury.

Plum, Pear, and Sweet Cherry.—The blossoms are swelling fast, and many of the former are expanded. Although it is hoped a return of cold weather may not take place, yet some preparation should be made for protecting the bloom, should the necessity arise to do so. No method is easier of application than that of sticking poles into the border 3 or 4 feet distant from the foot of the wall and reaching to the coping, and securing to the latter three or four-fold garden-netting, usually a sufficient covering at this season, whilst admitting ample light by day. The netting should be taken down as soon as the flowers have set, unless the weather is unusually cold. A quantity of this simple covering can be placed in position in a very short time. The netting should be fastened at the bottom edge to the poles in order to prevent its being blown about or against the trees.

Gooseberry Bushes.—These may be protected with branches of Spruce, Fir, or Laurel stuck around them; or what is perhaps better, a little dry bracken scattered thinly over them.

Bush and Pyramid Pear Trees are not so easily protected. Where of moderate size, four or five light poles, long enough to reach above the tops of the trees, may be tied together at the top, and the other ends be stuck into the ground around the tree. This will serve as a framework on which some thin covering may be placed, or a few branches tied on thinly to afford some slight degree of protection.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Winter-flowering Carnations.—The tops of young plants which have been potted into 60's should be pinched out as soon as it is seen that the roots have taken possession of the soil. The plants should at this date be harboured in a cold pit or frame, and when lateral shoots are produced after the stopping the plants should be shifted into 48's again, pinching out the points of the shoots when these are long enough, and the plants are well established in the pots. This stopping of the shoots is productive of bushiness and a free-flowering habit. Afterwards, the plants may be stood on a bed of coal-ashes out-of-doors, and later they should be afforded a shift —the last—into 6-inch or 7-inch pots.

Azalea indica.—Plants in need of re-potting should be attended to after flowering, and when growth has commenced. Clean, well-drained pots, a full size larger than the previous ones should be used; and for the compost use good hard fibry peat, a small quantity of broken charcoal, and a considerable quantity of silver-sand to give porosity. In filling in the soil round the ball, apply a little at a time, and ram it evenly and firmly with a thin potting-stick till it is as firm as the ball; having done this, place the plants in a temperature of from 55° to 60°, maintaining a moist atmosphere, and syringing the plants freely overhead to keep down thrip and red-spider. If the ball was thoroughly moistened before repotting, no water need be applied for a week or longer. As growth progresses, afford more air, and when it is completed, the plants may be stood out-of-doors.

Achimenes, Tydeas, and Gesneras.—The tubers of these various stove plants should now be placed in pans or boxes in which they are to be started, and earlier-started tubers into the pots or pans in which they are to flower. If an increase of the stock of any of these is desired, the tops of the shoots may be taken off, when 1 to 2 inches long, and pricked off in 5-inch pots to the number of eight or ten in the case of Achimenes, and five or six in that of Tydæas or Gesneras, and the pots plunged in a hot-bed, or placed in the propagating-frame. These take root readily, and flower well, as also the plants from which they were taken. All of the plants named should be grown not far from the glass in a warm pit or shed. The Achimenes do not succeed so well or flower so abundantly in a moisture-laden air as in a dry one; although in the latter red-spider is apt to cause trouble.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Three Species of Epidendrum of much merit are now in bloom, viz., E. Endresii, E. Wallisii, and the hybrid between them. All of the plants are in a forward state, and may be re-surfaced with living sphagnum-moss, or, when the flowers are over, they may be repotted, if the case demands it. Small pots or pans, almost filled with clean crocks, should be used, working in amongst the spreading roots a small quantity of sphagnum, and, in the case of E. Wallisii, some peat. The last-named and the hybrid may be grown in a sunny part of the Cattleya-house, and the first-named in a cooler and more shaded position of the same or similar house, affording each a plentiful supply of water, diminishing or increasing it in amount according to the state of the growth and the season of the year.

Oncidium ampliatum is an Orchid which always seems to be imported in its prime, as it usually grows smaller as time goes on. One reason of this retrogression is its extreme floriferousness, and being a cheap plant, cultivators seldom take the precaution of allowing it a year's rest by pinching out the flower-spikes as they would from more valuable plants. It is a warm growing species, subsisting for some considerable time in hanging-baskets, or placed near the roof according as the height of the house admits. Very little potting-material should be placed about its roots, and this should consist of peat chiefly, with clean crocks to fill the basket. During the summer when growth is active, much moisture is needed, but at other times but little, otherwise the bulbs will rot, or the leaves fall away. Bletia hyacinthina, now in bloom, will need large supplies of water until the foliage begins to decay. Sophronitis grandiflora having finished flowering, should still be given enough water to keep the compost in a well-moistened condition, likewise the pretty S. violacea now developing its growths. S. cernua, usually grown on a block, will need very little to keep its bulbs plump. Maxillaria grandiflora, having been kept on the dry side during the winter, should now be given water more frequently. When repotting this species, a small quantity of good fibrous loam should be added to the peat, and sphagnum-moss, its fine, almost hair-like roots finding greater nourishment if this be done. This is a fine cool-house Orchid when kept healthy, producing its flowers in abundance. Another desirable species is M. Sanderiana, whose flower-spikes are now developing, and on this account call for extra care when applying moisture, so that not any may lodge in the bracts enveloping the growing scape and cause disaster. The plant should be grown in shallow baskets suspended in the cool houses, and should not be disturbed until the flowers have faded.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Trees and Shrubs.—Attention should be given to all recently-transplanted trees and shrubs, first seeing that they are made secure against wind-waving, as the young roots will be pushing into the soil; and if the root-mass gets loosened, these roots break off, and growth is injured and retarded. The means of securing a plant may be by wire-guys, in the case of heavy-top trees and shrubs; stout stakes, to the number of two or three, in the case of less weighty plants, and one for a small one; but whatever is made use of, it should be effectual of its kind. Shrubs with but few roots when planted should be protected from the east wind, and shaded from full sunshine for the first season. Three stout stakes, with garden-mats fastened to them, form a way of shading them; and smaller shrubs may be protected with evergreen branches stuck into the soil. In dry weather syringe them overhead just as the sun is passing off them; it will keep them fresh till the sun rises. If the soil be porous, afford water heavily occasionally, and a mulch of manure after the first application. Water that has been warmed by the sun is better than well or pipe-water, as it does not lower the warmth of the soil, and thus check growth.

Kniphofias.—Clumps which were protected as advised in previous Calendars may now be exposed, but the old leaves may not be removed before the young growths are 1 foot high. If the soil is exhausted, lift the plant, remove a portion of the soil from the roots, and refresh the plant by adding plenty of rotten manure and some light loamy soil, and replant. Do not subdivide the patches, or do this but slightly. K. Uvaria glaucescens, U. grandiflora, and U. nobilis form grand masses of bloom, and look well when planted in wide spaces. Among shrubs of moderate dimensions, K. Tuckii is very handsome, and the earliest to flower, namely, in June. The strong glaucous foliage resembles that of a Yucca; the colour of the bloom is deep salmon-pink, shading to creamy-white. The new hybrids are very free-growing, and great improvements upon earlier forms, throwing up stout flower-spikes, and lasting a long time in perfection. Chloris, Lachesis, Obelisk, Ophir, Stella, and Henry Cannell have fine flowers, orange and yellow coloured. Leda, Matador, Pfitzeri, and Otto Mann, are of lovely shades of crimson and scarlet. The smaller forms, Leichtlini, distachya, corallina, Rooperi, and MacOwani, are brilliant in colour, and do best in elevated positions in the rock-garden. The present time is the best to plant, as if this operation be left until the autumn, the foliage is apt to rot, and destroy the crowns.

Begonias.—Stored tubers should now be examined, cutting away decayed parts, and dusting the cut surface with flowers-of-sulphur. Having overhauled the entire stock of tubers, place leaf-mould 2 inches deep in shallow boxes or trays, and lay each tuber on this layer about 1 inch apart, and place them in gentle heat to start. As soon as the tubers get plump, cover them to the depth of an inch with leaf-mould or Jadoo fibre, but afford no water before growth pushes through the soil; and when this is sufficiently strong, pot the tubers into 48's somewhat firmly, using a mixture of three parts yellow loam, leaf-mould, and sand. Place them in a cool frame, keep the lights close for a few days, and damp over and between the pots till roots form, and afterwards afford water carefully so as not to cause souring of the soil. Some tubers will be later than others in starting, and some may go blind. The larger tubers may be cut in half just between the growths, and potted in small pots. Let the tubers when potted be kept near the glass, and shade the growth from the sun. When the shoots are crowded some of them may be taken off close to the tuber, and inserted as cuttings in small pots under a hand-glass, where they will soon form roots and make useful tubers for another year. The yellow-flowered varieties are very distinct in growth and habit, but the deeper tints are lacking in vigour. These are best when kept by themselves, using less moisture and a few degrees more warmth.

Seeds.—The following seeds may be now sown in the open border:—Pæony-flowered, and other annual varieties of Poppies, Limnanthes Douglasii, Linums, Malopes, Mignonette, Nicotiana, Tropæolum, Hibiscus, Lathyrus, Clarkias, Calendulas, &c. Soil not heavily manured is best for these. This should be made level, and the seed sprinkled near the surface. Plants of Aquilegia, Campanulas, and other biennial plants raised in boxes, should be planted in borders, and in reserve garden for cutting purposes. Herbaceous plants that are to be added should be bought in at once to form good-sized plants to flower this year.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Tomatos.—The plants intended for planting outside should be potted before they get drawn and weak in the seed-pots, placing two in a 60 or three in a 48, using light, fresh soil mixed with road-grit. Let the young plants down to the seed-leaf in potting them, and afford tepid water with a fine rose-can to settle the soil. The pots should be stood in a warm frame, and afforded slight shade till established. Tomatos should be kept growing gently, and when large enough, repotted into 48's or 32's, from which they may be transferred to the open ground when the proper time arrives, and they have been suitably hardened off. If seed has not been sown, no time should be lost in sowing sufficient to meet the needs of this planting. The plants by June 1 should be fully 2 feet in height, and if some of the bunches of flowers have then "set," it will be a great advantage. Great care must be taken not to cause a check by exposure to cold air, affording very cold water at the root, &c.

Seed-sowing.—Seeds of Cauliflower for a large planting, and of Brussels Sprouts, Savoys, and Couve Tronchuda for a moderate supply, may be sown on a warm border, having previously levelled the land and raked it evenly and smoothly, and made it moderately firm. Sowing may be done in drills half an inch deep and 8 inches apart, or broadcast, hacking the seed into the soil with a rake. It is well, if the beds cannot be netted, to shake up the seed in dry red-lead. It is well to keep a memorandum of the times of sowing, and the names of the kinds and varieties, in case any of the labels should get removed. A pinch also of that valuable early Broccoli, Snow's White, should be sown.

Potatos.—Early, late, and mid-season varieties of Potatos may now be planted in bulk. If an exception be made, a few of Ashleaf may be preserved for planting late in July, for supplying new Potatos in the autumn. The strong-growing varieties should be afforded a space between the rows of from 2 to 2½ and 3 feet, when a better yield and less loss, should the disease attack the plants.

Beet.—Although as yet too early in the month to sow the main crop of Beets, some seeds of the Egyptian or Turnip-rooted variety may be sown on a warm border to afford an early supply of roots. Sow in patches of four or five seeds in drills, 1 inch deep and 14 inches wide; or they may be pressed in at 8 inches apart in rows, putting three seeds in each patch.

Vegetable - Marrows. — These are grown in a variety of ways, all of which answer well; and seed may be sown at any time from now onwards to May. I usually place three seeds in 4½-inch flower-pots filled with roughish loam and rotten stable manure, and stand these in a vinery, and when the plants are hardened off suitably in May, I plant them out on heaps of decaying garden-rubbish, or in trenches dug out 3 feet wide, and deep enough to permit of a good mass of manure being placed in them, and over all a layer of good soil formed into a flattish ridge, on which the plants are put out at 4 feet apart, and hand-lights placed over them till all risk from cold nights is passed. Vegetable-Marrows can be well grown on hills of half-spent manure; but for productiveness, a good soil made moderately firm, with not too great a run for the roots in rich manure, is best. Plants forwarded in frames should be kept thinned of the weaker bine, and afforded ventilation in accordance with the weather, and afforded water at the root, and suitable night coverings.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long Rood Ashton, Trowbridge.

Pot Vines.—The stoning period will now be far advanced, or even passed in the case of very early Vines in pots, and ventilation may therefore be allowed a little more freely. At the same time, there must be no extremes. A "chink" of air at night is beneficial when the berries have assumed the first stage of colour. Maintain a genial temperature by the aid of fire-heat, but a high night temperature should be avoided. There will be the same need for a periodic damping of the floor-space, at any rate for the time-being, as a change from moisture to a state of aridity would encourage insect attack. Water must be given to the roots in sufficient quantity and frequency to maintain the soil uniformly moist, and weak liquid-manure is best for this purpose. Such liquid can be obtained by soaking manures from the cow-yard, stable, or sheep-fold separately in tubs of water. Drainage collected from the farmyard in a tank affords an easy means of procuring the best of plant food, diluting it according to its strength and the purpose for which it is required. Bottom heat, arising from hot-water chambers, should now be slightly reduced; it will tend to a better finish being obtained in the fruit. The hot-bed of leaves and stable litter should be sufficient to furnish the required temperature without any or but slight additions, but in neither case should the heat be allowed to recede to a cool point. Attend closely to the stopping of all sublaterals, that the energy of the Vine be directly expended on the maturation of the crop.

Recently-planted Vines, instead of being allowed to make an unlimited length of rod, are best stopped periodically. If the point be removed after the cane has grown from 2½ to 3 feet, this will cause a direct strengthening of the stem growth, which will be very plainly illustrated later in the season. A leader may be chosen from the point where it has been stopped for the extension of the rod, and this again pinched when it has reached an additional length of 2 feet. A rod 6 to 8 feet long is a sufficient length to mature and retain upon a young Vine during one season, and the laterals beyond this may be regularly though not too closely pinched. The latter course is advisable in cases of extra strong-growing Vines, which, if kept unduly pinched, are apt to commence growth from the main buds.

Cut-back Vines intended for fruiting in pots next year should be given the same careful preparation; unnecessary lateral growth, or undue extension in length of rod being a waste of time and plant effort. Watering must be done with a regard to the state of the weather, and an excess must be as carefully avoided as drought. Until the pots have become well occupied with roots, it is better not to feed with strong stimulants, but when healthy and abundant root-action has been established, artificial or natural manures in liquid may be given advantageously.

Vine-eyes or Cuttings inserted early in February may soon be transferred into pots two sizes larger. If they have been plunged in a mild hot-bed up to this date, they would be better returned to the same (though not necessarily plunged), until they have taken hold of the new soil. Good turfy loam, with some old mortar-rubble or crushed bones, will be sufficient to use at this stage. A soft, sappy growth set up by the use of animal manures in the soil should be avoided. Vines need all the light available in the early as well as later stages of their growth. Light stakes should be given for their immediate support.

THE APIARY.

By Expert.

March has, in this district, been one long calm, with no rough winds to shake the catkin's pollen into the Nut-blossoms, nor whip the fragile Snowdrop's whiteness into a dirty brown. This anticyclonic period has been an advantage to the busy bee, whether foraging for pollen in the Crocus and Snowdrops, or culling the early sweets from the forward Palm, white Arabis, and other early flowers, or labouring incessantly carrying in water to supply the growing needs of the increasing family in the brood-nest. The calm weather and bright sunshine have enabled the bees to work in comfort, and with comparatively small loss of bee-life. The general opinion seems to be that breeding has commenced early this year, and consequently an extra run on the stores will result. No one at present, however, can tell if this early breeding will be of permanent benefit to the craft as a whole, or to any individual stock of bees; because if the young bees are bred out of season, they will be consumers only, and not producers, seeing that they cannot gather honey from barren fields. Nor do I remember seeing the fields look more barren than now for several years at this time of the year; night frosts have followed the warm sunny days, and have retarded the growth of vegetation, and kept things backward. Those who live in fruit-growing districts should try and take advantage of the early breeding, as by judicious management they may secure not only early honey, but also sweep the board in classes for honey of 1899 at the early shows, such as Royal Counties at Windsor, Essex Agricultural, and "Royal ' show at Maidstone.

Honey Imports.—The column of imports of foreign honey is interesting, and, I think, points to the fact that our industry, notwithstanding lower prices, must be growing. That bee-keeping is going ahead, that British honey and British bee-keepers are growing in favour with the British public, is patent to all observers. One cannot but notice, as one perambulates the large town, whether on foot, or bus, or tram, that the number of shops which stock honey and display the same in conspicuous positions are increasing. And it is gratifying to note in passing that the old time combination of "milk and honey" is still hand-in-hand. It is the dairyman who has taken hold of the honey trade.

Carbolic Cloths.—As far as my experience goes it does not hinder bees from going into sections, but I am quite sure that they needlessly irritate them, and I now never use them in manipulation. I find it far better to wring two or three unbleached calico quilts out in a solution of "Izal," one tablespoonful to a pint of water; then quietly peel off the quilt, drawing the wet one on at the same time. Let it remain a minute, then gently lift it for general observation as to strength of bees, &c. They will be quietly at work and seem to take no notice. Then replace the wet quilt, and taking another proceed to uncover one frame at a time, covering those inspected with the second wet quilt, so that none are exposed. A hive can be gone through, I find, without either excitement or the hint of a sting; while, when I have used carbolic the bees are all on angry buzz, seeming to say, "That nasty stuff frightens us so we don't know what to do; but, wait till we get our senses back, and then we'll pay you out," and so they do. I have gone through my small apiary of six stocks and not heard an impatient note, much less had a sting, from my dear little bees, by the above method.

TRADE NOTICE.

Mr. A. Hemsley, formerly with Mr. May, Dyson's Lane Nursery, Upper Edmonton, has engaged with Mr. Goodliffe as manager of his new nursery at Worthing, entering on his duties about April 15.

A Mammoth Willow.—We extract the following from the *Transactions of the English Arboricultural Society*. The tree was grown at Boreham, Essex, and measured when down 101 feet in length, 5 feet 9 inches in diameter, weighed upwards of 11 tons, and was as sound as a bell. It was planted in 1835, and was taken down on April 19, 1888 [query 1898], by Messrs. Warsop & Sons, for the sole purpose of making cricket-bats—1179 being thus supplied.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	APRIL 8	Royal Botanic Society, Meeting.
TUESDAY,	APRIL 11	Royal Horticultural Society of Ireland, Meeting.
WEDNESDAY,	APRIL 12	Royal Botanic Society's Exhibition at Regent's Park.
THURSDAY,	APRIL 13	Midland Daffodil Show in Edgbaston Botanical Gardens, Birmingham (2 days).

SALES.

TUESDAY,	APRIL 11	Imported and Established Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY,	APRIL 12	Palm-seeds, Carnations, Gladioli, Greenhouse Plants, &c., at Protheroe & Morris' Rooms.
FRIDAY,	APRIL 14	Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period March 26 to April 1, 1899. Height above sea-level 24 feet.

Remarks.—The weather during the week has been very mild and spring-like, with a remarkable absence of sun.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—46·5°.

ACTUAL TEMPERATURES:—

LONDON.—*April* 5 (12 P.M.): Max. 60°; Min. 43°.

PROVINCES.—*April* 5 (6 P.M.): Max. 55°, Yarmouth; Min. 45°, Aberdeen.

Fine; Light Showers.

The Ocean as a Reserve of Heat for the Earth and Air in Winter and Spring.

SUCH is the comforting conclusion suggested by the facts so lucidly stated by Sir JOHN MURRAY in a paper read before the Royal Society of Edinburgh on Monday, March 20. Sir JOHN stated that the deep-sea temperatures had been placed on equal surface projection maps, and from a study of these it was estimated that over 90 per cent. of the sea-floor was occupied by water of less than 40° F., 49 per cent. being 35° to 40° F., 41 per cent. between 30° and 35° F., and 3 per cent. under 30° F. On the 10,100,000 square miles between the shore and a depth of 100 fathoms, there were annual variations in the temperature; while on the 127,100,000 square miles deeper than 100 fathoms no annual variation of the temperature had been observed, unless off the coast of North America, where the Gulf Stream and Labrador current run side by side.

Having thus stated the main facts as to the temperature over the floor of the ocean, Sir JOHN proceeded to the second part of his subject—the maximum and minimum temperature of the surface of the ocean. Studied in a similar way to the ocean-floor, it was estimated that in the coldest months to the north and south of the equator, 75 per cent. of the area of the ocean is over 40° F.; while in the warmest month of the year, 87 per cent. of the total area of the ocean had a temperature over 40° F. There was thus a striking contrast between the temperature of the floor of the ocean and that of the surface waters of the ocean. It was also to be observed that the bands of equal temperature ran north and south on the floor of the ocean, owing to the north and south trend of continental shores, while at the surface of the ocean the bands of equal temperature ran east and west. The effect of these differences in the distribution of temperature on the planktonic and benthonic organisms of the ocean was then illustrated by reference to pelagic foraminifera and other marine animals.

However potential the temperatures of the floor and surface of the sea, and its main currents and cross-currents in making the earth habitable for man, horticulturists may be pardoned at the close of an old-fashioned March of normal severity, and a prodigality of dust, cheap this year at a guinea a bushel, consisting of millions of acres of sand into ash-heaps (model seed-beds), if they also pause to note the great saving ministry of the sea is thus becoming the warming-pan for earth and sky, and the powerful and universal protector of our fruit-crops, now slowly advancing into blossom.

Fortunately, the latter are probably a fortnight later than usual; and the later the blossoming-time, the fuller the harvest, as earth, air, and sea get warmer as the year gets older. Fortunately for us, as fruit, flower, vegetable, and plant-growers, the cold water sinks to the lowest depths or floor of the ocean, and the warmer floats on the surface; while ice in its forming expands, becomes lighter, rises to the surface for the sun and air to convert it once more into warmer water, and enable it to resume its part in the warming and watering of the earth. With the major area of the surface currents of the ocean at a temperature of 40° there is no real danger of gardening nor gardeners being frozen out. And then we have the Gulf Stream for our special help, raising and genialising our climate in a most remarkable manner. At this critical season, with our fruit crops trembling in the balance, when snaps of cold are apt to come upon us with equal celerity and severity, it is well to be reminded of some of the greater and constant protective forces ever ranged on the side of the cultivator.

KEW. — A correspondent writes:—"The pleasure of a visit to Kew now-a-days is, to many people, greatly spoilt by the want of hospitality on the part of the officials so far as bicycles are concerned. It is bad enough to have to part with the machine at the gates at all in face of those well-kept and inviting gravel-tracks, but it is more distressing still to have to leave the favourite Elswick or Beeston-Humber outside the gardens, perhaps for some hours, on a stretch of grass unprotected by a roof of any sort whatever, and at the mercy of hail, snow, or thunderstorms. Under present circumstances, too, what can be easier than for the bicycle thief to take his choice of desirable machines, while his friend distracts the attention of the gate-keeper? Surely the British cycling public would not be asking too much were it to suggest that a weather-proof shed, provided with bicycle racks might be put up inside, at any rate, the main entrance to the Gardens. To the uninitiated there would seem to be ample space for such a refuge by the side of the shelters that are provided for confiscated baggage, or outside the garden along the wall whereon the time-tables are displayed."

THE SURVEYORS' INSTITUTION. — The next ordinary general meeting in London will be held on Monday, May 1, 1899, when a discussion will take place on the "Agricultural Holdings Bill," prepared and brought in by Mr. CHANNING and others. The chair will be taken at eight o'clock. The annual dinner of the Institution will be held in the King's Hall, Holborn Restaurant, on Wednesday, May 10, 1899, at half-past six o'clock precisely.

SINGLE BLUE HYACINTH "CHARLES DICKENS."—Besides the single blue variety, says the *Florilegium Haarlemense*, a double blue and a single lilac Hyacinth are known by the same name—both are sports from the single blue Charles Dickens. The well known single purple Hyacinth of the same name is from an entirely different origin, and should therefore be designated by another appellation. On the other hand, a pale lilac-coloured Hyacinth, Charles Dickens, not so generally known, is a sport from the single blue variety here represented. Finally, the double rose-coloured Hyacinth Lohengrin is worthy of mention—it is a sport from the double blue Charles Dickens. The above facts show the marked tendency of the race of Charles Dickens Hyacinths, to produce "sports," a circumstance that is not met with in such a high degree in other Hyacinths. Connected with this fact, undoubtedly, is the phenomenon so frequently noticed, that the spike of a single blue Charles Dickens is half blue and half red; while the dividing line between the two colours, as a rule, lies in a spiral around the cluster of flowers.

NOMENCLATURE OF PLANTS. — "At the present time, the only dictionary of the plants of the whole world, with their synonyms down to date, is the *Index Kewensis*; BRITTON and BROWN, and others cited, are excellent authorities. They are undoubtedly correct in their position, that many of the names they propose to be adopted should have been adopted; but they have a hard task in trying to upset the accepted nomenclature of the whole world, throwing everything into confusion, and utterly demoralising general literature, because some generations ago somebody blundered. In every other affair of life, even to the collection of an honest debt, there is a period when it becomes outlawed. The justification is, that by the failure of the creditor to collect in time, too many innocent interests become involved. In like manner, there can be no reason why thousands should be made to suffer by a change in plant names, because credit for the original was suffered to sleep for a century." *Meehans' Monthly, March*, 1899, p. 48.

YUCCA GLORIOSA IN A LONDON GARDEN.—On several occasions we have presented our readers with illustrations of this fine garden plant in flower in various localities in this country. We have recently received a photograph which represents a beautiful specimen flowering in a very small garden at Nunhead, London. Mr. HAMPTON's garden is but 21 feet square, and the Yucca is planted in the centre. The garden is quite hemmed in with large Poplars and brick walls, yet last season the plant produced a spike with 530 blooms, and after being cut down early in October, it threw up another spike with 27 flowers that were open during the first part of November. Surely, this is a plant that is worthy the suburban gardeners' appreciation.

Leyden.—The directorate of this famous garden, vacant by the death of Professor Suringar, has been entrusted to Dr. J. M. Janse, of the Buitenzorg Botanic Garden.

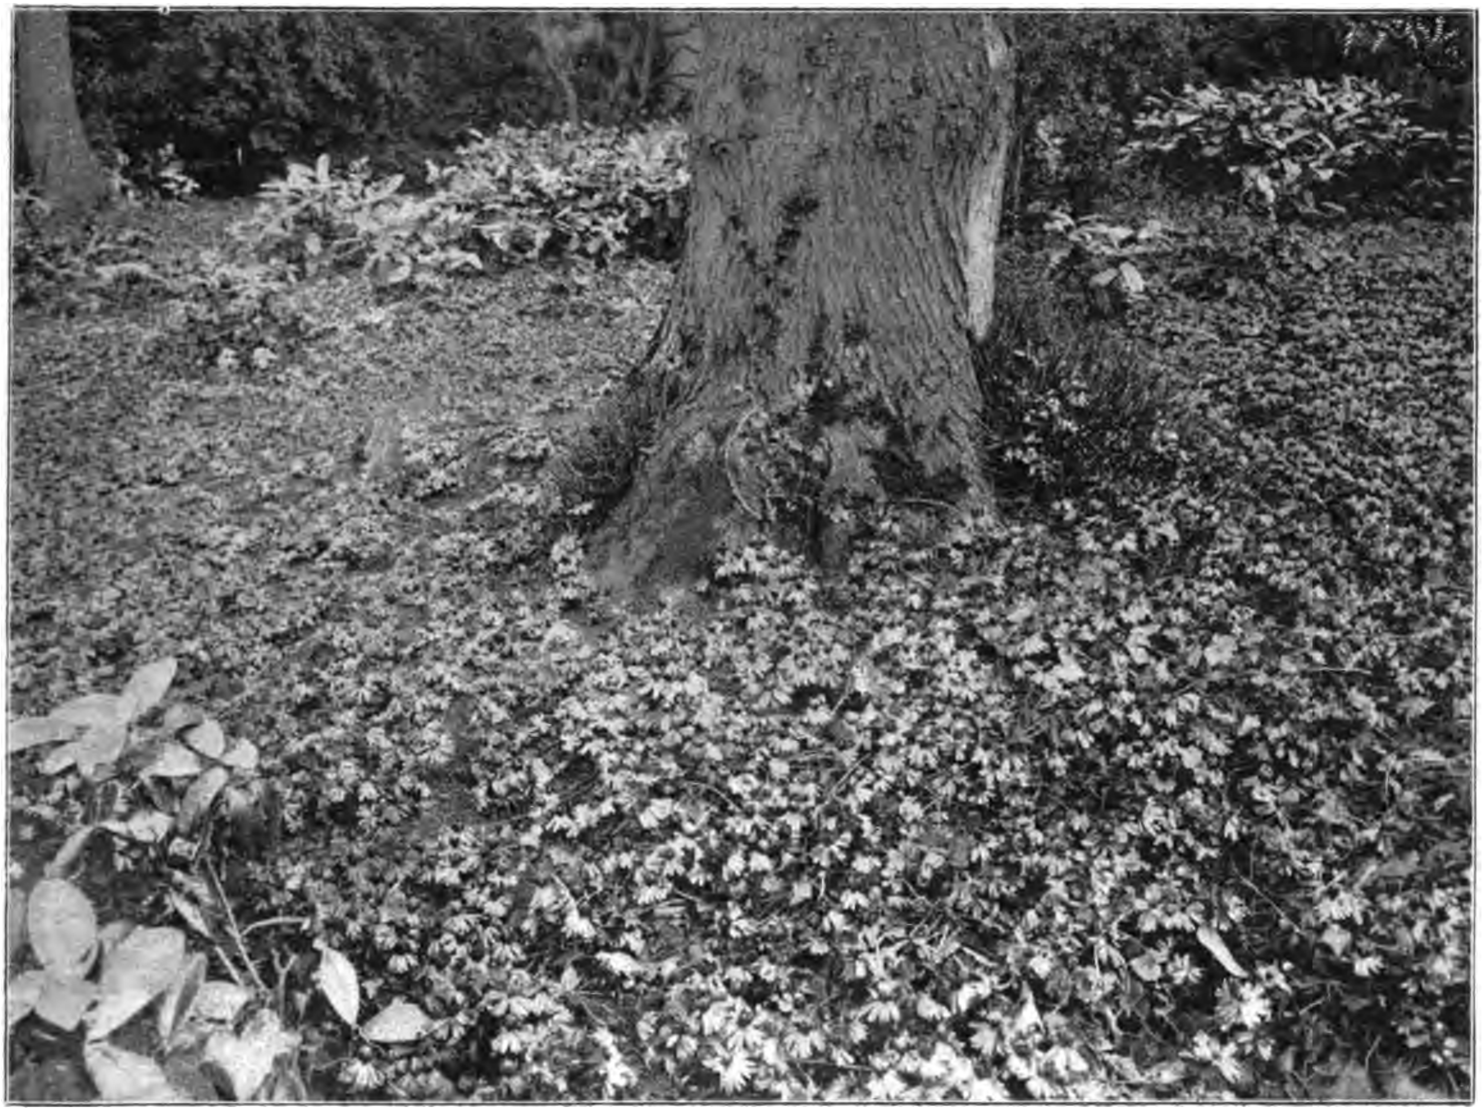

Fig. 82.—A display of winter aconites in the grass in Normanton Park, Stamford. (See p. 219.)

The National Chrysanthemum Society's Annual Report for the year ending Dec. 31, 1898, a copy of which we have recently received, contains a mass of useful information to cultivators of Chrysanthemums for exhibition purposes, or for the decoration of the garden only. Immediately following the report and balance-sheet presented by the Executive Committee, are given the lectures upon the Chrysanthemum rust-fungus, that were delivered by Mr. Percy Waterer and Mr. Geo. Massee at the Conference held in the St. Stephen's Hall, Royal Aquarium, on October 11. These papers, and the discussion that took place in connection with them, are worth the study of those who last season suffered from the attacks of this pest. The report of the Investigation of Sites, &c., Sub-Committee is given in full, and members may, therefore, discover the reasons that led this sub-committee, in the first place, to report in favour of holding the shows of the Society during 1899 in the Crystal Palace, Sydenham. The amended rules of the Society, and the later results of the work of the Classification Committee in regard to strictly incurved varieties, and to synonymous, or too-much-alike varieties, are items of information necessary to the exhibitor; and the awards of the Floral Committee should be useful as a guide to what are the most essential of the recent novelties. The September show, that we have repeatedly urged was useless, or even worse, has been discontinued, at any rate for the present year. There will be an early autumn exhibition on October 10, 11, and 12, the great mid-season competition on November 7, 8, and 9, and an early winter exhibition on December 5, 6, and 7. All of the above shows, together with the meetings of the Floral Committee, will be held, as usual, in the Royal Aquarium, Westminster. A large amount of interest will doubtless be excited by the class at the November show for twelve vases of Chrysanthemum blooms, for which a first prize of £20 is offered by Mr. H. J. Jones. Mr. Davis' class for specimen blooms, with a view to encouraging distinctness of colour, will also constitute an interesting feature.

On the Influence of the Removal of the Runners of Strawberry Plants upon their Fertility.—There are amongst Strawberry-growers different opinions respecting the removal of the runners of Strawberry plants. Whilst some say that it is best to cut off the runners as often as possible, others say it is better not to remove them before fruiting. To decide the question, Mr. Duerkoptf, Wolfenbuettel, has made the following experiments. Three hundred young Strawberry plants of the American variety Sharpless were planted in the middle of August, 1897, in six rows, fifty plants in each row, the plants were all of equal size and strength. At the beginning of September, when the plants began to grow, the runners of all the plants were cut off. From this date, September 5, the plants of row I. were deprived of their runners weekly, viz., on September 12, 19, 26, October 3, 10, and 17. Those of row II. were deprived of their runners fortnightly, on September 19, October 3 and 17. Those of row III. were deprived of their runners every third week, on September 26, October 17, and so forth, each following row being treated a week later, that is, row IV. every fourth week, row V. every fifth week, and row VI. every sixth week. On October 17, 1897, the experiment was interrupted, as no more new stolons or runners were formed. At the beginning of June, 1898, the first new runners appeared. On June 5, 1898, the stolons of all plants were removed. Then the plants in the single rows were cultivated in the same manner as during the previous year until

June 19. During the week, from June 19 till 25, the number of leaves, fruiting-stalks, and fruits of each of the 300 plants were counted. The result was: the plants of row I. had together 1175 leaves, 177 fruiting-stalks, and 916 fruits; those of row II. 1137 leaves, 159 fruiting-stalks, and 841 fruits; those of row III. 1139 leaves, 167 fruiting-stalks, and 860 fruits; those of row IV. 1009 leaves, 127 fruiting-stalks, and 628 fruits; those of row V. 970 leaves, 105 fruiting-stalks, and 618 fruits; those of row VI. had 928 leaves, 73 fruiting-stalks, and 482 fruits.

Division.	Leaves.	Fruit-stalks.	Fruits.
Each plant produced on average :—			
Row I.	23·50	3·54	18·32
Row II.	22·74	3·18	16·82
Row III.	22·78	8 34	17·20
Row IV.	20·18	2·54	12·56
Row V.	19·40	2·10	12·36
Row VI.	18·56	1·46	9·64

Except as to Row III., the results show that it is best to remove the stolons as often as possible. As to row III., the experimenter considers that some peculiarities in the soil may have influenced the result. The remarks concerning the ripening of the fruits in the different rows are interesting. On June 21 there were ripe :—

Row I., from 916 fruits, 53 fruits = 5·78 per cent.
Row II., „ 841 „ 59 „ = 7·01 „
Row III., „ 860 „ 36 „ = 4·18 „
Row IV., „ 628 „ 55 „ = 8·75 „
Row V., „ 618 „ 78 „ = 12·62 „
Row VI., „ 482 „ 54 „ = 11·20 „

Dr. Dammer, Gross Lichterfelde, Berlin.

CRACKING OF PEARS, ETC.—The *Gartenflora* and the *Bulletin d'Arboriculture* publish a figure representing the effect of the Bordeaux Mixture as a preventative of cracking in Pears, as a consequence of the growth of the Fusicladium dendriticum. The mixture in this case is made by mixing one kilogramme of copper-sulphate, one of lime, and a hectolitre of water, in the manner often detailed in these columns. The mixture, it must be remembered, is used as a preventative, hence it is used in the form of spray as soon as the fruit is set, and again when the fruit is half-grown. The figures of Apples so treated, and others of the same kind not so treated, is very striking.

THE LIFE OF PLANTS UNDER ADVERSE CONDITIONS.—Prof. REYNOLDS GREEN delivered, on March 14, a very interesting lecture on this subject, which is published in full in the *Pharmaceutical Journal*. When our columns are less crowded, we may hope to extract some portions of the address, which obviously are of greater importance to horticulturits even than to pharmaceutists.

ASEPTIC TREATMENT OF VINES.—According to *the Annales Agronomiques* for March 25, Dr. BARRETTO, a vine-grower of Brazil, applies aseptic treatment to his vineyard; that is to say, preventatives to preserve the plants against disease-bearing germs. To effect this, Dr. BARRETTO decorticates all the old wood, disinfects the whole stock, sterilizes the wires by heat, burns the dry leaves, washes the posts in copper solutions, and pulverises the whole vineyard with these salts as a preliminary operation. Dr. BARRETTO considers that perfect asepsis can only be ensured in stony grounds which restrict unwholesome and moist exhalations, and enable disinfection to be more conveniently carried out. These preparations yielded good results to the experimenter, and preserved his Vines from rot, which is prevalent in the State of St. Paul. In a further series of experiments, dusting with sulphate of alumina proved equally efficacious.

PROTECTION AGAINST PLANT-DISEASES.—In a recent periodical (*Praktische Blätter für Pflanzenschutz*, January, 1899), Professor J. E. WEISS, of Freising, gives results of some interesting experiments. He wished to test whether whole plants could not be treated as we do seeds, namely, by immersing them in some solution which would kill any fungi present without injuring the plants. He immersed plants of Hazel and Oak in spring-condition without leaves, also Box and Privet with leaves, in a 1-per-cent. solution of copper-soda mixture. After being twenty-four hours there the roots were uninjured, and the plants on being planted-out grew perfectly. He recommends that all plants brought into a garden from outside sources should be treated in this mixture for one or two hours before planting, thus ensuring the killing of any fungi they might have carried in. The 1-per-cent. copper-soda solution is made in the proportions—3 oz. copper-sulphate, 3½ oz. washing-soda, and 4 gallons of water. The two substances are dissolved separately in enough hot water, then poured together, and water added up to 4 gallons. This is a weak solution, but for delicate plants may be still further weakened by adding more water. Where plants are suspected, it seems a safe precaution to take. We wait to see what are the results of further experiments which the Professor has in hand.

NYMPHÆA "MARIE LAGRANGE."—The *Revue Horticole* of the 16th ult., contains a coloured figure of a hybrid Nymphæa as large as N. devoniensis of gardens, the petals being rose-coloured with a central light stripe. It was raised by M. LAGRANGE, of Oullins (Rhone), between the nearly allied N. Lotus and N. dentata, and, judging from the figure, is a very fine variety.

THE THIRTY THOUSAND DOLLAR CARNATION.—The raiser of Mrs. T. W. Lawson Carnation, Mr. PETER FISHER, is, says *Gardening*, a Scotchman by birth, and a thorough gardener by training. His nursery at Ellis, Mass., is entirely devoted to the Carnation.

MR. JOHN BARRON, of the firm of Messrs. WILLIAM BARRON & SON, Borrowash, Derby, having been married recently, about seventy employés of the firm were entertained to dinner on the 25th ult. In the interval between the dinner, and an enjoyable concert that followed, Mr. and Mrs. BARRON were presented with a handsome clock, and hearty expressions of good wishes.

DEVON AND EXETER GARDENERS. — The subject-matter of the last paper of the session, delivered last Wednesday, was, "Pelargonium Culture from an Amateur's Standpoint," the essayist being Mr. GEO. C. CRABBE, Exeter. Many useful hints on potting and the treatment of show, fancy, and zonal Pelargoniums, and of striking cuttings, were given in the paper. For the annual summer outing of the Association in July, it was decided to visit Sidbury Manor, the seat of Sir CHARLES CAVE, Bart., near Sidmouth. The spring session of this Association has been a most successful one.

THE TORQUAY DISTRICT GARDENERS' ASSOCIATION continues to exert a salutary influence upon horticulture in this much favoured western locality. The seventh annual report just to hand, shows how active the executive has been during the recent winter season, when fortnightly meetings have been held for debating useful subjects in connection with gardening. There have been twenty-six new members elected during the year, and the Association has a balance of £11, which it is intended to use for the purpose of adding desirable books to the members' library. Dr. R. HAMILTON RAMSAY is the esteemed President of the Association, and Mr. FRED C. SMALE the Hon. Sec.

PRESENTATION TO MR. JOHN LAZENBY.—At their meeting held on Thursday night, March 30, at the White Swan Hotel, York, the committee of the Ancient Society of York Florists presented to Mr. J. LAZENBY, who has resigned the post of secretary, an illuminated testimonial and a purse of gold, subscribed for by members of the Society and other friends. Mr. J. C. MILBURN took the chair. Mr. J. PILLMOOR made the presentation, and expressed the regret of the President (Alderman MCKAY) that he was unable to attend. Mr. LAZENBY, who has been secretary of the society for twenty years, was resigning on account of ill-health. In thanking the promoters and subscribers, Mr. LAZENBY alluded to the great progress made by the society, mentioning the fact that the first Chrysanthemum show was held in the house in which they were met together in 1879.

THE FOGS DURING MARCH have wrought great destruction amongst Peaches in the suburbs of London that happened to be in process of stoning at the time. We are acquainted with several instances where all of the fruits have since fallen. This is a rude reminder to the suburban gardener that his position is, after all, attended with serious disadvantages.

APPLES FROM THE ANTIPODES.—The officials of the Orient Steamship Co. enable us to state that the *Ormuz* has sailed for Tilbury with 17,000 cases of Apples, and the *Victoria* with 10,000 cases of the same fruit. The former ship will probably arrive on the 29th inst.

WAKEFIELD PAXTON SOCIETY. — At the ordinary weekly meeting of the members of the Paxton Society, held at the Strafford Arms Hotel on April 1, a good attendance was present, over which Mr. SWIRE, art master of the Technical and Art School, presided. The lecture on this occasion was entitled "Gardeners," by Mr. TWIGGE, jun., nurseryman, Wakefield. A discussion followed the lecture, and a hearty vote of thanks was accorded the lecturer.

GREAT EXHIBITION AT ST. AMAND, GHENT.—We are desired to state that a free entrance ticket, available for the whole time that the exhibition is open, will be presented to all nurserymen (not of Belgian nationality) who may be desirous of visiting the exhibition. Application should be made without delay to the secretary of the Ligue Horticole l'Union, Mont St. Amand, Gand, Belgium.

PUBLICATIONS RECEIVED.—*Journal of the Board of Agriculture*, March, 1899. This opens with a report on the British crops of last year, supplementary to that published in December, 1898, and indicating an "exceptionally high standard of production reached." There are also papers on the imports of agricultural produce, Indian agricultural exports, and various allied subjects.—*Familiar Wild Flowers*, by F. E. Hulme, F.L.S. (Cassell & Co.); popular edition, part 1, with ten coloured plates.—*Nesting Boxes for Birds*, by Joseph King. Being No. 1 of the Peasants Arts Pamphlets (Peasant Arts Society, Queen's Road, Bayswater). An attractive illustrated brochure advising the making of nesting-boxes for birds: starlings, tits, redbreasts, &c., near dwelling-houses, and speaking in commendation of birds generally, to the exclusion, of course, of the "cheeky, thievish," and universally unpopular sparrow.—*Proceedings and Journal of the Agricultural and Horticultural Society of India*, for October-December, 1898. This includes a paper by Mr. A. J. B. Gisseleire upon a "sport" of Canna "Partenope" recently figured in our columns; advice to amateur irrigationists; exhaustion of fertile soils, and other items.—*Canadian Horticulturist*, March. Among the articles we note the following :—Packing Apples for export; wrapping fruit and vegetables; Stirling Horticultural Society; good results from spraying in Eastern Ontario; Apples for export, and varions shorter communications.—*Die Vegetation der Erde*, A. Engler und O. Drude (Leipzig, W. Engelmann). To be noticed more fully shortly.—*Tijdschrift voor Tuinbouw*. Vierde jaargang; achtste aflevering.—From the Australian Association for the advancement of science, a paper by J. F. Bailey on *Plants of the Rabbit-infested Country, Bulloo River, S. Q.*, a useful catalogue, although "not to be taken as representing the flora of the district; it will give some idea of those plants which were able to withstand the severity of the climate of those parts, and produce food when all else is parched up. It was impossible to identify those which had sprung up, owing to the recent rains, and causing the country to look so green, as they were, of course, in too young a state." The paper is illustrated from photographs supplied by Mr. C. J. Pound, Government Bacteriologist of Queensland.—From the same Association comes another paper by J. F. Bailey on the *Flora of the Islands of Torres Straits and the mainland about Somerset*.—*Experiment Station Record*, Vol. xiii., No. 1, U. S. Department of Agriculture, containing papers on: The Physiological Rôle of Water in Plants, by E. Gain; Action of Different Colours upon Plants, C. Flammarion; Formation and Assimilation of Asparagin, O. Loew; Occurrence of Nitrates in Germinating Plants, E. Schultze; Nitrogen Assimilation in the Cotton Plant, C. E. Coates and W. R. Dodson; Sub-irrigation in the Greenhouse, W. J. Green and E. C. Green; Cabbages, H. P. Gould; Garden Peas, B. C. Buffum; Apple Culture in Wisconsin, E. S. Goff; Currants, S. A. Beach; The Russian Thistle, E. O. Wooton; Potato Blight, L. R. Jones, &c.—*National Nurseryman*, March.—*Agricultural Gazette of New South Wales*, Vol. x., Part 1, Jan., 1899. This contains articles on Insect and Fungus Diseases of Fruit Trees and their Remedies, Messrs. Allen, Blunno, Froggatt, and Guthrie; Exotic Grasses (Paspalum dilatatum), J. H. Maiden; Useful Australian Plants (Agropyrum velutinum); Native Fodder Plants, and Botanical Notes, by J. H. Maiden, and Orchard Notes by W. J. Allen.—U. S. Department of Agriculture, Division of Entomology, *The Chinch Bug*, by F. M. Webster.—*Bulletino della R. Societa Toscana di Orticultura*, Febbraio.

PLANT PORTRAITS.

Acacia alata, *Revue de l'Horticulture Belge*, March.

Azalea indica, "Ceres," white, striped with red; good form; *Revue de l'Horticulture Belge*, April.

Bomarea Carderi, Masters, *Garden*, February 25.

Dioon edule var., *Garten Flora*, March 15, figs. 32—39.

Echinocactus Whipplei, Engelmann, *Meehans' Monthly*, March. The flowers are represented of a pink colour.

Fendlera rupicola, *Revue Horticole*, March 16, woodcut (Saxifrageous shrub).

Fugosia hakeifolia, *Garden*, March 25. A Hibiscus-like Malvad, with linear leaves; flowers pale lilac, 3½ inches in diameter.

Helianthus mollis, *Garden*, March 4.

Hyacinth Charles Dickens, single blue, raised from seed by Mr. Marten Mulde, *Florilegium Haarlemense*, t. 25.

Kniphofia Nelsoni, *Garden*, March 11.

Ligustrum japonicum variegatum, *Revue de l'Horticulture Belge*, April.

Lissochilus Graefii, Kranzlin, a terrestrial Orchid, with loose spikes of flowers, each flower about 5 cent. (2 inches) across, with spatulate brown sepals, spreading petals, white within, yellow externally, fore-lobe of lip yellow; *Garten Flora*, t. 1460.

Magnolia Watsoni, *Gartenflora*, February.

Narcissus, 1, Pseudo-Narcissus, var. Emperor; 2, bicolor Empress; 3, incomparabilis Sir Watkin, *Florilegium Haarlemense*, t. 27.

Plum Gloire d'Epinay, resembling the Prune de Monsieur, very productive; fruits large, globose, purple, ripening before the Green Gages. A chance seedling; *Revue Horticole*, February 16.

Plum, Satsuma, a Japanese variety, with red flesh; *Bulletin d'Arboriculture*, March.

Rose, Mrs. W. J. Grant, a fine plate of a fine Rose; *Garden*, March 18.

Russelia sarmentosa, *Revue de l'Horticulture Belge*, March.

Tulips, Rex rubrorum, double red; and La Candeur, double white, *Florilegium Haarlemense*, t. 26.

SPRING FLOWERS ON GRASS.

This, like not a few other new things in horticulture, is not so novel as might be supposed. Twenty or more years ago the late Mr. William Thomson showed, from data gathered from several gardeners, that many old mansions possessed attached lawns on which spring-flowering plants had been known to have flourished as far back as the "oldest inhabitant" could remember. By means of the same individual, the large expanse of half-kept ground here, called "The Wilderness," is known to have been more or less a large spring garden on grass during the whole of the present century. Unfortunately, there is no means of determining with certainty how or when the flowers came there. We do know, however, that a "Wilderness" was planted some time near the middle of the seventeenth century, and between 1700 and 1707 it was much enlarged and laid out in straight walks, which were composed of grass. Sixty years later, the "natural" style caused another alteration. The straight walks, with their tall hedges on each side, were obliterated, and "serpentine" walks introduced. Gravel was substituted for grass, and the interspaces, where shrubs and common flowers were cultivated, were laid down in grass. It is not exceeding the bounds of probability to suppose the tens of thousands of Primroses of various hues which now carpet acres of ground to have originated from the "Wilderness" plantations. The wild Tulips, double-flowered Daffodils, Cowslips, and Star of Bethlehem doubtless descended in the same way.

Left, practically, to a state of Nature, these semi-wildings afford matter for thought. The Primroses, with quaint-looking flowers, whose petals stand wide apart from each other as the arms of a windmill in miniature, are decidedly of erratic temperament—spots they rendered beautiful thirty years ago have to-day scarcely a representative left; and other portions known to have been clothed with grass only, are now thickly covered with plants. Their rate of progress is not rapid. Some seedlings from an improved strain that I planted in a bare spot have, in a dozen years, spread from the centre no more than as many yards. Sometimes the seedlings form a thick clump, the flowers all of one colour, as if a capsule with its seed had been dropped on the spot. At other times they are thinly dispersed round the parent plant; they cultivate sociability, and so we find them crowding each other under the shade of tall Hollies, or cuddling close to the base of some giant tree. Those, however, whom fate has placed in the opener glades spend their lives, which are rather short, more apart.

Snowdrops display much individuality. Out of hundreds very few can be found that agree in all particulars. Some are very early, others late in flowering; some tall, some dwarf. The flowers of a few are very diminutive. Both outer and inner segments vary greatly in shape, so much so that instances occur where the inner are almost identical with the outer. The markings of the former, again, are very varied; green, yellowish, none! Snowdrops decidedly prefer the shade of large-growing trees; but they also wander to the open, and a seedling is sometimes found three to six yards from the nearest group. How the seeds are carried I have not discovered. As the seed-pods fill, the stem naturally declines to the ground, and by the time the seeds are ripened, the capsules are buried out of sight in the grass, so that some outside agency must help in the dispersion of these isolated plants.

Narcissus minor is another plant that seeds freely, and among the seedlings very great diversity occurs in the size and the shape of the flowers. This plant, however, does not wander, and the young seedling are always found close to the parent. I have seen seedlings from no other Narcissi. In addition to the old-established Narcissus incomparabilis, N. poeticus, and the common yellow, many kinds have been introduced during the last twenty years. A method, at once cheap and successful, is to flower the bulbs the first year in pots and then in May to transfer them to the "grass," either planting in small clumps as grown in pots, or singly shaking them out. One of the prettiest thus grown is N. ornatus. I have also established one or two sorts of Polyanthus narcissus.

Hyacinths die out in the course of a few years, nor are Tulips any longer lived. Tulipa sylvestris, however, spreads in the most extraordinary manner by means of stolons which it makes in early spring.

Crocuses are most difficult to naturalise; not on account of soil or dislike to the position, but because of the fondness mice and some birds have for the corms. Pheasants are extremely fond of them, and, when visiting some gardens near Ayr a few years ago I was shown examples of the ravages of the common rook, which dig up the roots and consume them. Mice may be kept from the corms by means of very close-meshed wire-netting laid an inch or two above masses of the corms, the whole being covered with soil. I have also tried deep planting, that is about 10 inches below the surface, and have found birds circumvented in this manner. I always plant out forced Crocuses after flowering, but strong-growing varieties alone ought to be selected; dark purple flowers are unsuitable, and best of all is the Golden yellow.

The pretty blue Scilla præcox succeeds well, and also Ornithogalums, of which none surpass O. arabicum. Alliums also are in an eminent degree suited for growing in Grass, but in the case of these we are encroaching on the flowers of summer. *R. P. Brotherston, Tyninghame, N.B.*

[Our illustration (fig. 82, p. 217), shows how well the Winter Aconite, Eranthis hyemalis, succeeds under conditions such as are above mentioned, and under trees. The photograph was obligingly forwarded to us by Mr. J. Butler, gardener at Normanton Park, Stamford.]

SCOTLAND.

THE CRUICKSHANK BOTANIC GARDEN FOR ABERDEEN.

Thanks to the munificence of Miss Ann Cruickshank, the public of Aberdeen will shortly possess a first-class botanic garden and museum. Before proceeding with the laying-out of the gardens, the trustees appointed under the bequest consulted Mr. Nicholson, of Kew Gardens, who visited Aberdeen, and made a personal examination of the ground. That gentleman's report has been the basis on which the arrangement of the gardens has been laid.

In the old Gymnasium School, arrangements will be made for the study of systematic botany, with laboratory accommodation and lecture conveniences. The trustees have it in view to construct at some future time a suite of rooms running westward from the back of the main block, for the study of physiological botany, with suitable laboratory and other accommodation. It is estimated, however, that such an extension would cost nearly £3000. At the south end of the present main building, a granite structure is to be erected, to serve as a botanical museum Its dimensions are to be 50 feet long, 36 feet wide, and over 30 feet high to the apex of the roof. The building, which will have a most graceful appearance, will be lighted from the roof, and will be open to the public.

In regard to the gardens proper, a careful examination has shown that there is a depth of about 2 feet of good black soil, very suitable for the purpose in view. The main entrance to the gardens will in the meantime, at all events, be the present gateway in Chanonry. From this entrance a main walk will lead round the south end of the museum, and then strike almost due west, through the centre, from end to end of the ground—which, altogether, is between 5 and 6 acres in extent. From either side of the main walk, subsidiary walks will carry the visitor to all parts of the gardens. A portion of the ground in the south-east corner, at present used as a market-garden, will be retained for a propagating-ground for the botanical garden; and another piece, about half an acre in extent, will be set apart for the use of the Agricultural Department of the University of Aberdeen. Practically, all the rest of the ground will be laid out in plots for the culture of herbaceous plants, after the manner of the Royal Gardens, Kew. The small building in the south-west corner of the ground, intended at one time as an isolation hospital for the Gymnasium School, will be utilised as accommodation for the gardeners. The gardens are to be free to the public under as favourable regulations as it is possible to frame. The plans, which have had the full approval of the trustees, have been prepared by Mr. Bennet Mitchell, architect, in conjunction with Dr. James W. H. Trail, Professor of Botany, Aberdeen University, who has taken a close personal interest in the carrying out of the scheme. *K.*

HOME CORRESPONDENCE.

EUCALYPTUS.—In reference to Dr. Bonavia's remarks, I may say, that one of the leading druggists in Rome told me that the medical men there had made a series of experiments about the medicinal value of Eucalyptus-oil, or eucalyptine, as it is called, and that they attach small value to it. On the other hand, the very great efficaciousness of the trees for drainage purposes is beyond all dispute. *H. E., Mentone.*

THE CAMELLIA IN ESSEX.—The enclosed Camellia-blooms and foliage were cut from a tree growing out-of-doors and over-hanging the lake, being reached in fact by the aid of a boat. There is a very old man here who has worked on the estate fifty years, and he says that the Camellia was planted before his time. The tree must have withstood some very hard winters during half of a century. *Edwd. Collins, Cranbrook Hall Gardens, Ilford.* [If the tree has been in such a position for the length of time stated, it is a notable specimen. The flowers sent are small, of course, but the foliage is very good. Ed.]

MARÉCHAL NIEL ROSE.—Referring to Mr. Fish's useful remarks concerning the disease Maréchal Niel Rose is so very subject to, I think two considerations have to be borne in mind in the endeavour to find a remedy. That it is a matter of great importance none will gainsay who have any knowledge as to the immense numbers of plants which are purchased and die, after a year or two's growth, or an attempt to grow. Primarily, it is probable that the method of growing-on the plants so vigorously in unnaturally high temperatures, before they are disposed of, may be the cause of lack of success when they are ultimately planted out. Certain it is, that plants grafted at or below the ground-line, notwithstanding this initial vigorous growth, succumb the most. May not contact of the Maréchal Niel wood with the cold ground in a soft, immatured state, be the cause of both this and knotting? This variety neither succeeds thus, nor properly long together, as a standard much pruned-back, as is usual with standards. Its nature and desire is to make vigorous growth; in furtherance of which, I have known plants under glass, cut down annually, succeed well. Buds grafted about 3 or 4 feet high upon Gloire de Dijon make vigorous shoots. I have had dual ones from such buds 14 feet long in the season; and it is possible by this system of budding greater success may be obtained. *William Earley.*

THE ABNORMAL GROWTHS ON MARÉCHAL NIEL ROSE.—Your correspondent, "D. T. F.," with many other writers on the swelling of the stem of this Rose, usually refers to it as a disease, and also as being constitutional. But whilst I admit that it is constitutional, I cannot admit that it is disease or ill-health. The general cause of this swelling of the stems of the scion seems to arise rather from the excessive elaboration of sap through the agency of strong leafage, thus leading to the formation of cambium by the return or aërated sap, in a way too free and rapid for the capacity of the stock to utilise it, unless the stock be of similar gross or strong-growing nature. But as I have said, with large experience of M. Niel worked on to gross growers such as were previously named, this cambium swelling, miscalled canker and "gout," never occurred. Has anyone tried that grossest of all Roses, Crimson Rambler, which strikes so freely as cuttings, as a Maréchal Niel stock. This should answer admirably, as it is in itself a free cambium creator. But the working should not be onto small shoots. The plants should be induced first, after being well rooted by hard cutting back, to send up one of its characteristic strong growths from the base of the stem, and that should be the budding medium. Then there can be no doubt but that scion and stock would swell together freely enough. Without doubt the primary cause of the trouble with Maréchal Niel has been in working it persistently on stocks that, whilst excellent for other Roses, are unfit to meet its peculiar requirements. *A. D.*

THE WEATHER IN NORTHAMPTONSHIRE.—I am afraid in some cases the severe frosts and bitter cold winds during March have done considerable damage. Peach and Apricot-trees, however, have not suffered greatly, as only those blooms that were fully expanded have been killed. Roses have suffered very much indeed. I scarcely know at present how they will succeed this year, but they are not likely to be very fine. I examined our Onion-bed on March 29; the seedlings are about an inch high, and under a small magnifying glass the tips seemed as if they had been frozen, and had since damped off. It is to be hoped that such is not the case generally. A singular circumstance in connection with the frost is that the Tree Mallow (Lavatera arborea variegata) does not seem to have taken any harm, except the very young tips that have grown this year. I do not think the spring-sown Peas or the Spinach have been hurt, and at present some early Turnips that were through the soil appear to be all right, but they will most likely damp off. A friend about 5 miles from Lamport has lost 40 poles of Potatos, the frost having penetrated the soil to such an extent that he fears they are quite spoiled. The most severe frost we have had has been 20°, and our elevation is 450 feet. *H. Kempshall, Lamport Hall Gardens, Northampton, March* 30.

IVY LEAVES EATEN BY AN INSECT.—On page 189 of the *Gardeners' Chronicle*, a correspondent, R. D., asks if any one has had similar experience of Ivy leaves being eaten. We have here an old Oak tree, whose branches are cut off to within a few yards of the trunk, the whole of which is covered with Ivy, and forms an object of beauty all the year round. Last August something was noticed to be eating the Ivy leaves, especially those near the base, and I made a close examination without detecting anything. But the next day I had success, for I found on a stalk-leaf of an Ivy, a caterpillar 1¼ to 2 inches long, almost of the same tint as the Ivy wood; indeed, so much so, that it was not easy to distinguish it. It had four legs at the ends of the body, and with these it can fix itself very firmly on to the wood or leaf-stalk [a looper, Ed.]; it is also very strong, for while fixed firmly to the wood with its hind legs, it will reach about in search of food all round. After this discovery, more than a hundred caterpillars were captured during the next few days. In some instances they had bitten holes in the leaves and round the edges, and some were found suspended by a thread. I have seen these pests before on trees, but not in such numbers, nor on an Ivy plant. [The caterpillar was probably the larvæ of Boarnica rhomboidaria, Ed.] *A. T., Birmingham.*

SALADS IN ENGLAND.—Why do English gardeners so much neglect salads? On March 13, I came to Sidmouth, S. Devon, an eminently favoured locality. The hotel is in a grand position, surrounded by choice Conifers, such as Pinus insignis, &c., with Camellias in flower, and a walled-in kitchen garden of 7 to 8 acres, with conservatories, &c. Here the only salad to be seen was Mustard-and-Cress, most ostentatiously served at every meal, as if a great delicacy; but no Lettuce, Endive, or even Celery; no Radishes, nor fresh Mint for sauce. How different from the north of France, where, with a much worse climate, one has, at this time of the year, Radis *rond à bout blanc* served each day at breakfast, and delicious Lettuce salads at every meal. I came on to Falmouth, an even more favoured locality in the midst of private gardens, which not even the Riviera can equal—where one sees Tree Ferns, Palms, Embothrium, Dicksonias, and other very choice plants in full luxuriance. Here I am able to get a little tough Cabbage-Lettuce, and some even tougher Endive, most sparingly served, and that is all. Can it be that the cooks prefer to send to the greengrocer for French Lettuces? I am afraid there is something in this; but the hotel keepers do not give these to their guests. *R. Milne-Redhead.*

AN OLD SEED HOUSE.—I have just met with a catalogue of Dutch bulbs, including Cape and others, issued in 1846 by Westmacott & Co, Seedsmen and Florists, 156, Cheapside, opposite St. Pauls. As I can find no trace of this firm in a trade list published in 1853, I assumed that it had ceased to exist by that time. In looking through this list, it is seen that in those days (regarding the catalogue as a fairly representative one) the double Hyacinths were much more numerous than the single, and but few of the varieties of the former have survived to this day, and even fewer of the single varieties. The only named variety of the vernal Crocus was David Rizzio. There were only eight varieties of early Tulips, and the same of double, while the named varieties of Polyanthus Narcissus were much more numerous than they are in the present day. *R. D.*

MALVERN HOUSE CONSERVATORY, MAPPERLEY, NOTTINGHAM.—The illustration in the last issue of the *Gardeners' Chronicle* was very gratifying to me, as it showed how well Seaforthia elegans had done after the lapse of sixteen years. Great credit is due to Mr. Nicholas German, who designed the Malvern House conservatory and stove, and planted the gigantic Palm; and as a plantsman and orchidist he was exceptionally successful, as he established the Arnot Hill collection, and flowered Odontoglossum Hilli and O. Arnotti for the first time, and carried out the principal features in both gardens. It was a gardening treat to visit either place. *T. Edington, Tortworth Court, Falfield, Gloucestershire.*

PRIMULA OBCONICA AND P. SINENSIS.—Having suffered from the irritation which the leaves of Primula obconica cause when touched, it may be of service to those who, like me, are affected by this plant to know that Condy's Fluid rubbed on the affected parts affords great relief. It may also act similarly when irritation is caused by P. sinensis. *C. S., Ipsden.*

—— With reference to the extract from Dr. Kirk's paper in the *Lancet*, which appeared in the *Gardeners' Chronicle* for March 18, p. 171, I may be permitted to make a few remarks. For several years, whenever I have seen P obconica grown, I have made a point of inquiring if anyone who had to work with the plants felt any ill effect. I have also made enquiries regarding the precise ways in which the sufferers were affected. From what I have learned, I should put down the number of those affected as considerably fewer than 20 per cent. of those who handle or touch this Primula. In the majority of those affected only a severe irritation, more or less temporary, is caused by simple contact. Should working with the plant be persisted in, eczema is frequently produced, and I have been told of at least one case of severe blood poisoning arising from persistently handling the plant. In some instances the simplest touch in brushing past a plant causes very painful irritation. The foreman in one English botanical garden informed me that if his bare arm touched a leaf when he was going along the greenhouse path the irritation produced was so painful that he had to put his arm under a water-tap to soothe the pain. Dr. Kirk's second "fact," viz., "that some constitutions are specially susceptible, while others enjoy immunity" I have proved by several experiments upon myself, without however proceeding to the extreme of the patient who "chewed the flowers and swallowed the juice." I have touched my lips with leaves, stems, roots, and flowers without feeling anything the worse. What I have learned also corroborates what Dr. Kirk says with regard to his patient that "she had handled the plant for one or two years before the first blistering of the lips was experienced. One of my friends cultivated this Primula for at least two years before he felt any evil effects, but he had at length to give up growing it. Dr. Kirk's qualified statement that "apparently the majority of sufferers have been females, although the evidence on the latter point is not decisive," is not confirmed by my experience. It may be that females are more apt to seek medical advice, and that thus more cases, from their sex, have come under the notice of medical men than from among males. I am of opinion that the number of males affected is relatively as high as of females. One would have thought, too, that gardeners, whose hands were hardened with their work, and whose skins were apparently less sensitive, would have been comparatively immune; yet my inquiries lead me to think that soft and tender skins are not more liable to feel the irritation than others. I have been told of a curious case, which I can hardly credit, but which I give for what it is worth. It is that of a traveller who asserts that if he enters a place in which Primula obconica is grown he feels uncomfortable. Whether we are to set this down as a "traveller's tale," or as an instance of some occult influence, it is not for me to say. It is said that it is not even necessary that the plant should be seen before the uncomfortable feeling begins. The tale sounds incredible, yet stranger things have been found to be true. From a gardening standpoint, it is highly desirable that we should have a little more light upon these irritative properties of so valuable a plant. This must be my excuse for the length of this note. *S. Arnott, Carsethorn, by Dumfries, N.B.*

Lonicera Standishi.—Dr. Dammer's remarks on Standish's Honeysuckle, in your late issue, is a well-deserved tribute to its worth. In Essex, I have had it bloom, and in a somewhat shady situation—on the north side of somewhat overhanging tree—as early as the second week in March. It is a quaint plant, as its numerous spreading branchlets become covered with flowers, the fragrance of which is very pronounced and sweet, before a leaf appears. Kept slightly pruned, so as to give it a bushy shape, without giving it too much the clipped, rounded, wretched suburban garden form, it makes a desirable plant for the second row in shrubberies; and even a bed planted with it, dotted with dwarf Arundo donax variegata, edged with Daphne Cneorum, has telling effect during the spring and summer months. *W. E.*

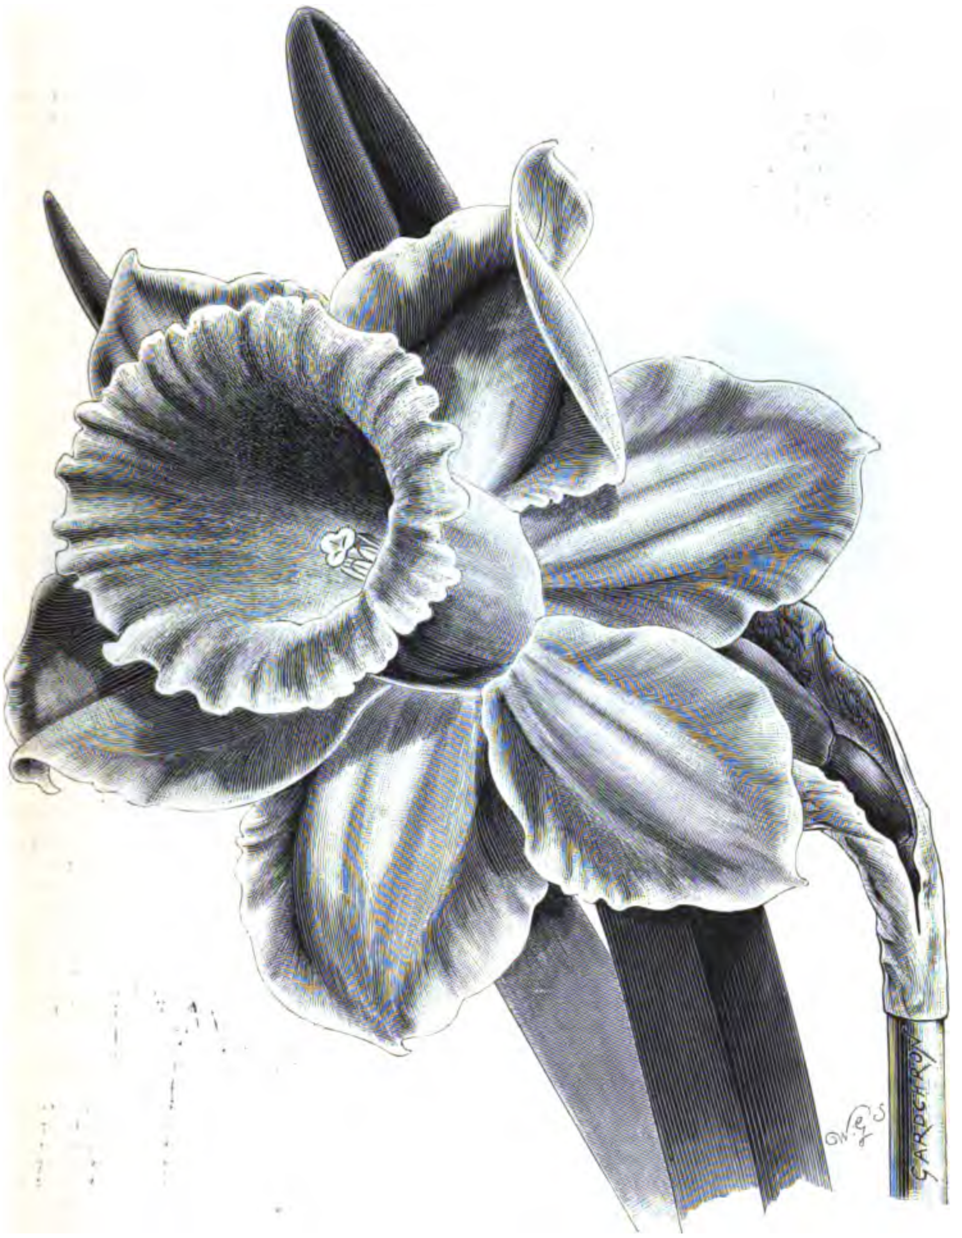

Fig. 84.—Trumpet Narcissus "King Alfred": colour of flowers rich gold.
Awarded a First-class Certificate at the last meeting of the Royal Horticultural Society.
(See Report, on p. 207 of our last issue.)

A few good Camellias.—It is to be very much regretted that these exquisite flowering shrubs should have been ousted from the popularity they once enjoyed by the Chrysanthemum and other plants of more recent introduction, but, although relegated to the background for a time, it is pleasing to see that they are gradually regaining the position they once held and which they so richly deserve, for there are few plants to equal them for conservatory decoration in the early spring months. This being so, a list of a few good varieties may be useful to some who, may be, contemplate planting a few at this season. I give below a list of fifteen varieties which, I think, are deserving a place in any garden. Taking them alphabetically we begin with the old alba plena, which is too well known to need any comment; Beauty of Waltham, pale blush, sweetly pretty, and hard to beat; C. H. Hovey, bright crimson, fine, a free bloomer; Chandleri, rich crimson-scarlet, and, like the foregoing, a free bloomer; delicatissima, blooms like a double Petunia, creamy-white, exquisitely delicate; Duchess, similar to Beauty of Waltham, but deeper in colour, very pretty; fimbriata, like alba plena, but with fimbriated petals; Lady Hume's Blush, softest blush, a great favourite with the ladies; Mathotiana, deep glowing red, massive blooms—a grand thing; also its counterpart, Mathotiana alba, similar in all but colour, which is white, as its name implies; Marchioness of Exeter, rosy-cerise, a grand thing, and worthy a place in any collection, free bloomer; Montironi Vera, very solid, pure white blooms, which show up well against the deep green foliage; Conspicua, rosy pink, blotched with white, a greatly improved Doukelaari; Corallina, rich deep red, very showy; tricolor, flesh-coloured, flaked with a deeper tint of the same colour, a grand acquisition. These last three are semi-double varieties, which are becoming well known, and gaining in favour, and justly so, and should be planted by all who have the requisite space. *E. H. S., Herts.*

MARKET GARDENING IN THE CHANNEL ISLANDS: JERSEY.

(Continued from p. 205.)

Mr. H. Becker's Nursery.—On a busy morning in September last I entered the covered market. The quantity of the Belladonna Lilies on sale was truly surprising, and they were of unusually intense colour. Other hardy flowers included Dahlias, Asters, and diverse herbaceous species. The Pears, Grapes, Figs, and Melons to be had were excellent. Subsequently, when passing through the town, my attention was drawn to some Orchids in flower in the window of a shop in Beresford Street. Upon inquiry, I was informed they were grown at the Cæsarean Nursery, St. Saviour's, to which I was afterwards accompanied by the proprietor, Mr. H. Becker.

This nursery has been entirely remodelled by Mr. Becker since giving up the Imperial Nursery, the famous spot where the late Mr. C. B. Saunders grew so many of the large Pears that years ago made Jersey specially famous for this luscious fruit. When the Cæsarean Nurseries were taken over, many of the pyramidal and bush fruit-trees were moved from the Imperial Nursery and planted at the new place. When firmly established, these and many other trees will doubtless produce fruits equal to any that have been gathered in days gone by. It may appear incredible, but for one fruit of Belle de Jersey Pear Mr. Becker has many times received the sum of 10*s.* and even 15*s.* The care bestowed upon the fruit-trees is evident. The summer shortening of laterals is duly performed, and the centre of the trees are kept sufficiently open to admit the necessary air and sunshine, and when the fruit is set in the spring every encouragement is given to the trees by the application of manures, either as a liquid or as top-dressings. Careful thinning is done, that no ill-formed or inferior fruits may remain. In September, when many of the fruits are well advanced, numbers of them are protected from the ravages of birds and wasps by being enclosed in muslin bags. Similar methods are practiced all over the island.

One's first impressions of Mr. Becker's nursery are agreeable. A broad walk runs right through the grounds, and it is spanned by many arches, which are covered with freely-growing climbers. The land is divided by Privet and Yew hedges. Near to the centre of the nursery is a large dwelling-house, which was then in the hands of the builder, though a part was in use as an office and storehouse for bulbs, rendered necessary by the Daffodil industry. Here Mr. Becker has in contemplation the establishing of a school of horticulture, in some respects similar to those on the Continent. Rooms are being built for a number of young men, who will be taken as appreutices to obtain a thorough knowledge of plant and fruit culture as practised in Jersey. The island is capable of producing a greater quantity of fruit than it has hitherto done.

Immense quantities of Tomatos and Melons are grown here, and the produce shipped to the mainland. Tomatos, naturally, succeed very well out of doors here, but there are houses devoted to them also. A favourite variety is "The Cropper," and its name is a good one, as it is free in setting, produces large clusters of medium-sized fruits, and bears well to the top of the plants, occasionally 8 feet high. The vineries are especially good. A house originally filled with Muscats of Alexandria now accommodates an equal number of Vines of that variety and Appley Towers. No fire-heat is applied to the house, still excellent results are obtained. The varieties Appley Towers and Muscat of Alexandria Mr. Becker intends to grow more largely, but Black Hamburgh and Gros Colmar will not suffer neglect. It is wonderful how well Vines succeed in Jersey, seeing that in many instances no preparations whatever are made when the canes are planted, beyond the simple building of a house and the planting of the Vines in the ground outside. But the roots are subsequently afforded repeated applications of stable-manure or chemical foods.

Of Orchids grown by Mr. Becker may be mentioned Dendrobium Wardianum and D. nobile, Cattleyas Harrisoni, violacea, Gaskelliana, and Mendeli; Cœlogyne cristata, Chysis aurea, Odontoglossum citrosmum, Epidendrum vitellinum major, Oncidium Lanceanum, Cypripediums insigne, barbatum, and leucorrhodum. All of these have proved useful for the supply of cut-flowers. The Red Currant Comet, &c. (figured in *Gardeners' Chronicle*, 1896, Vol. xx., p. 137), I noticed in some quantity. The growth of the bushes is unusually strong and distinct, and the crop of fruit and length of the bunches is said to be astonishing.

In the grounds of the nursery were large quantities of Abies Pinsapo, A. nobilis, and A. Nordmanniana, Green and Golden-leaved Euonymus in ten thousands, and standard and dwarf Rose-trees are features of the out-of-doors department.

A number of German and Italian prunes are being cultivated, which it is hoped may prove remunerative. The trees are very vigorous, and Mr. Becker has hopes of their ultimate success. If these should be capable of producing fine ripe fruits in September, the season of choice Plums would be considerably lengthened. *From a Special Correspondent.*

A RECENTLY-CERTIFICATED APPLE.

IN our present issue we take the opportunity to illustrate a variety of Apple that was given an award by the Fruit and Vegetable Committee of the Royal Horticultural Society on March 14. ALLEN'S EVERLASTING (fig. 83), is a fairly old variety, of about medium size and regular outline. The large and open eye is set in a moderately deep basin, while the slender stalk, rather more than half an inch long, is also set in a wide and deep cavity. In colour, the fruit is green, with but few streaks of red, but the green becomes yellowish as the fruits ripen. Primarily a dessert Apple of rich flavour, it is also a good kitchen fruit, and keeps well until June. The award, now somewhat tardily given, was a First-class Certificate, the specimens being shown on that occasion by Mr. J. Masterton, Weston House Gardens, Shipston-on-Stour. The fruits we have figured were kindly supplied us by Messrs. Geo. Bunyard & Co., Maidstone. It may be interesting to add that there were thirteen dishes of this variety exhibited at the Apple Congress, held at Chiswick, in 1883.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

Present: H. J. VEITCH, Esq., in the Chair; Dr. Müller, Rev. W. Wilks, Rev. G. Henslow, Hon. Sec.; Visitor, Mr. Lees.

Flow of Sap in a Sycamore during Frost.—Mr. T. R. Bruce, The Old Garrsop, New Galloway, sent the following communication:—"I noticed icicles hanging on a newly-cut branch during the whole of last week, and steadily increasing, although the mean temperature of the week was only 30°. The mean temperature of March 24 was only 25·7°. The cut-branch would be about half-an-inch in diameter, and some pounds weight of icicles, or pints of sap, have flowed out during the week, and it still continues to flow. The maximum and minimum temperatures were as follows:—19th, 42·5°, 21°; 20th, 42·5°, 23°; 21st, 38·5°, 15°; 22nd, 38°, 21·5°; 23rd, 37·5°, 21·5°; 24th, 40°, 11·5°; 25th, 43°, 23°."

Aberrant Forms of Narcissus.—Mrs. F. M. Cooper sent some flowers—partly fasciated, partly double, and with coherent ovaries, &c., not unusual sports under cultivation.

Carnations and Chrysanthemums attacked by insects, &c.—Mr. Lees, of Trent Park, New Barnet, exhibited specimens of Pinks and Chrysanthemums, which were forwarded to Mr. McLachan and Mr. Michael for examination.

Hybrid Narcissi.—With regard to the spontaneous hybrid sent to the meeting on March 14 by Rev. C. Wolley-Dod, Mr. Henslow stated that the pollen was quite shrivelled and probably useless, as Mr. Wolley-Dod had found to be the case with other hybrid Narcissi. He sent also a spontaneous hybrid between N. triandrus and the Daffodil. The pollen of this also proved quite effete. He also sent flowers of N. Johnstoni, a supposed species intermediate between N. triandrus and the Daffodil, but it resembled the latter much more closely than the one mentioned above, as the corona was almost exactly that of the Daffodil, but of a paler yellow. The pollen proved to be very bad, but still many grains were apparently quite perfect. Mr. Wolley-Dod says that "it is found in various forms, having established an independent existence over large areas of Portugal and N.W. Spain." He adds that it has never been known to seed. The variety sent is called "Queen of Spain," and is the most abundant.

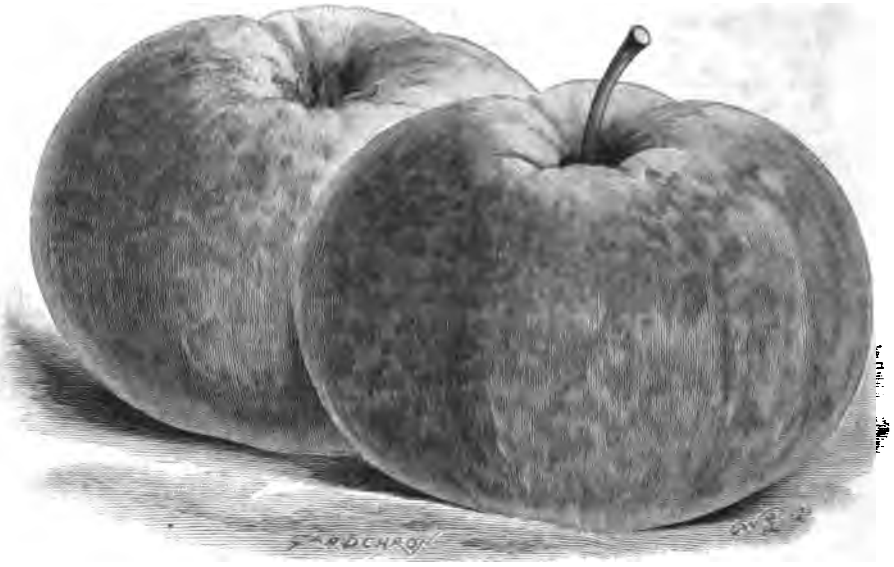

FIG. 83.—DESSERT APPLE, "ALLEN'S EVERLASTING."

PEOPLE'S PALACE HORTICULTURAL.

MARCH 25.—The East End amateur gardeners made an excellent display, the season considered, on the above date.

Hyacinths, in collections of six and three, and the classes for plants of different coloured varieties, as well as three bulbs in a pot, brought a most creditable display; and the same may be said of Narcissi and Tulips. Not less praiseworthy were the pots of Polyanthus Narcissi, and single and double trumpet varieties. It was just a little early for the Tulips, still some very good blooms were staged. There were collections of flowering plants, chief among them Azaleas, Cinerarias, Richardias, &c.; and collections of foliage-plants were remarkably good.

READING GARDENERS'.

MARCH 27.—At the fortnightly meeting, on the above date, "The Arrangements of Hardy Plants in the Garden" was the subject of a lecture given by Mr. ALEXANDER WRIGHT, of Falkland Park Gardens, South Norwood.

Mr. Wright pointed out that no branch of gardening was so important as that of the arrangement of plants in gardens, and as it was such a large question, he would treat it under three headings, viz.:—First, Trees; second, Shrubs; third, Herbaceous and Alpine Plants and Bulbs.

Practical hints were given as to the arrangement of varieties, harmony of colour, and positions most suitable for planting. The system of "massing" was recommended in place of that of "dotting," and of making selections of plants instead of collections. A very animated discussion followed, in which the question of massing gave rise to much controversy and difference of opinion.

Mr. STANTON, of Park Place Gardens, Henley-on-Thames, exhibited some splendid heads of Sutton's Commodore Nutt Lettuce, its compact appearance recommending it as a first-rate variety for frame-work.

THE NURSERYMEN, MARKET GARDENERS', AND GENERAL HAILSTORM INSURANCE CORPORATION, LIMITED.

MARCH 27.—The fourth annual general meeting of the above Corporation was held at Simpson's, Ltd., Strand, London, on the above date. Mr. Harry J. Veitch presided, and there was a good attendance of shareholders. The Chairman gave some interesting figures, showing the growth of the premium, income, and business, as follows:—

Year 1895–6:—Policies in force, 235; premium income, £681 1s. 9d.; square feet covered, 10,408,161; value insured, £135,215 16s.; claims paid, £288 17s. 4d.

Year 1896–7:—Policies in force, 346; premium income, £889 11s. 5d.; square feet covered, 13,886,095; value insured, £179,366 11s. 1d.; claims paid, nil.

Year 1897–8:—Policies in force, 550; premium income, £1360 17s.; square feet covered, 20,098,104; value insured, £263,590 19s. 1d.; claims paid, £1532 17s. 5d.

Year 1898–9:—Policies in force, 749; premium income, £1736 0s. 6d.; square feet covered, 25,619,760; value insured, £343,439 7s. 8d.; claims paid, nil.

The working expenses had been reduced from £40 10s. 8d. per cent. of the income in 1895-96 to £22 9s. per cent. in 1898-99. The whole of the cost of formation of the corporation (£399 4s. 4d.), and of furniture (£40 7s. 8d.), has been written off. £650 had been set aside as reserve for unexpired risks. The report was unanimously agreed to, as was the recommendation of directors, that a dividend of 5 per cent. for the year, and a bonus of 5 per cent. be paid, and that £200 be placed to the reserve fund, and the balance carried forward. At an extraordinary general meeting, held immediately after the annual general meeting, it was resolved that a further issue of 5000 shares of £5 each be made at a premium of 4s. per share, and that £1 4s. be called up between now and June 1, 1899. This will make the subscribed capital £50,000, and the paid up capital £10,000. The premiums on new issue will go to the reserve fund.

ISLE OF WIGHT.

APRIL 1.—The Isle of Wight Horticultural Improvement Association held their third annual non-competitive exhibition of Daffodils and spring flowers at Ventnor on the above date.

Being Easter time, the local gardeners, unfortunately, could not render the assistance which they wished, but still the standard of excellence reached in the previous year was well maintained, and Messrs. BARR & SONS showed 200 vases of Narcissus, thus affording the gardeners of the island a standard at which to aim in the cultivation of Narcissus. The Isle of Wight is a place admirably suited for the cultivation of these lovely spring flowers.

The chief exhibitors were Messrs. W. W. SHEATH, W. RUSSELL, A. J. COLE, C. SMITH, W. S. BARNES, and G. HONEYBOURNE.

The term "accumulated temperature indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. *Principal Wheat-producing Districts*—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. *Principal Grazing, &c., Districts*—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending April 1, is furnished from the Meteorological Office:—

"The *weather* during this period was mild, and unsettled very generally, with frequent and considerable falls of rain in the west and north, and occasional slight falls in the more southern and eastern parts of the kingdom.

"The *temperature* was above the mean, the excess ranging from 2° in 'Scotland, N., and E.,' to 6° in the 'Midland Counties,' and 'Ireland, N.,' and to 7° in 'Ireland, S.' The highest of the maxima were recorded, as a rule, on April 1, and ranged from 66° in 'England, S.,' and 65° in the 'Midland Counties,' and 'England, S.W.,' to 57° in 'Scotland, W.' The lowest of the minima were registered on the 26th, when they ranged from 26° in 'Scotland, N. and E.,' and 29° in 'England, E.,' to 40° in the 'Channel Islands,' and 41° in 'Ireland, S.'

"The *rainfall* greatly exceeded the mean in Scotland, especially in the west and north, and to a lesser extent over Ireland and in 'England, N.W.,' but in almost all the English districts the fall was less than the normal.

"The *bright sunshine* was deficient in all parts of the kingdom, the percentage of the possible duration ranging from 35 in the 'Channel Islands,' and from 23 in 'England, N.W. and S.W.,' to 14 in 'Scotland, N.,' and 'England, N.E.'"

GARDENING APPOINTMENTS.

Mr. Robert Galbraith, for the last five years Gardener to **Ed. Martin**, Esq., at Heathfield, Wimbledon, S.W., as Gardener and Overseer to **Alex. Wylie**, Esq., M.P., Cordale, Renton, N.B.

Mr. W. Henry Cork, as Gardener to Captain **Grassiot**, R.N., Hampton Lodge, Seale, Farnham, Surrey.

Mr. William Williams, late Gardener at Guilsborough Grange, as Gardener to **C. E. Paget**, Esq., Great Houghton House, Northampton.

Mr. G. E. Moorman, as Gardener to Lieut.-Col. **Gaskell**, Rose Leigh, Woolton, Liverpool.

Mr. W. Dearling, for four years Foreman in Messrs. **Hugh Low & Co.**'s nurseries, Clapton, as Gardener to **F. H. Johnston**, Esq., Green Bank, Plumbley, near Knutsford.

Mr. George Impett, formerly General Foreman at Tongswood, Hawkhurst, as Head Gardener to **W. C. Cripps**, Esq., The Lawn, Camden Park, Tunbridge Wells.

Mr. John Gosswiler, Assistant in the Garden Department, Hyde Park, has been appointed by the Portuguese Government to take charge of the Government Gardens in the province of Angola.

MARKETS.

COVENT GARDEN, APRIL 6.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Potatos.

Saxons, Snowdrops, Maincrops, &c., 55*s*. to 75*s*. per ton; Up-to-date, 80*s*. to 90*s*. do.; Dunbar Maincrops, 85*s*. to 95*s*. Seed in variety. *John Bath*, 33 & 34, *Wellington Street*, *W.C.*

Remarks.—The new consignments of Tasmanian Apples appear in good condition, fresh and healthy; home-grown Apples are now practically over; Oranges are coming to hand wastey, some very bad; this week, I think, will finish the French Apples, which have been coming very good. Asparagus is now arriving in variety, both as to size of heads and quality, also size of bundles, which vary considerably.

FRUIT AND VEGETABLES.

Glasgow: *April* 5.—The following are the averages of the prices recorded since our last report:—Lemons, 6*d*. to 1*s*. per dozen; Nuts, Cobs, 4*d*. to 8*d*. per lb.; Prunes, 6*d*. to 8*d*. do.; Apples, Canadian Spy, 14*s*. to 18*s*. per barrel; Western State Russets, 18*s*. to 20*s*. do.; Oranges, 4*d*. to 8*d*. per dozen; Grapes, home, 2*s*. to 4*s*. 6*d*. per lb.; do., foreign, 6*d*. do.; Tomatos, Guernsey, 4*d*. to 8*d*. per lb.; do., Scotch, 5*d*. to 8*d*. do.; Parsnips, 5*s*. per cwt.; Leeks, 1*s*. 9*d*. to 4*s*. per dozen bunches; green Mint, 6*d*. per lb. bunch; Onions, 4*s*. 6*d*. to 5*s*. per cwt.; do., Portugal, 10*s*. to 13*s*. 6*d*. per case; Carrots, 2*s*. 9*d*. to 4*s*. 6*d*. per cwt.; Cucumbers, 4*s*. 6*d*. to 6*s*. per dozen; Lettuces, round, 1*s*. 6*d*. per dozen; Radishes, 1*s*. 6*d*. per dozen bunches; Horseradish, 1*s*. 9*d*. to 2*s*. per bundle; Mushrooms, 1*s*. to 1*s*. 3*d*. per lb.; Beetroots, 6*d*. to 7*d*. per dozen; Mustard and Cress, 3*d*. per punnet; Turnips, 2*s*. 6*d*. per dozen large bunches; Broccoli, 2*s*. to 2*s*. 6*d*. per dozen Seakale, 1*s*. 9*d*. to 2*s*. per bush; Celery, 1*s*. to 2*s*. per bunch.

Liverpool: *April* 5. — *Wholesale Vegetable Market*. — Potatos, per cwt., Maincrop, 3*s*. 4*d*. to 4*s*.; Bruce, 3*s*. 3*d*. to 3*s*. 9*d*.; Champion, 2*s*. 10*d*. to 3*s*. 4*d*.; Turnips, 8*d*. to 1*s*. per dozen bunches; do., Swedes, 1*s*. 4*d*. to 1*s*. 6*d*. per cwt.; Carrots, 3*s*. 6*d*. to 4*s*. 6*d*. do.; Parsley, 10*d*. to 1*s*. per dozen bunches; Onions, English, 7*s*. to 7*s*. 6*d*. per cwt.; do.; foreign, 2*s*. 9*d*. to 4*s*. do.; Cucumbers, 3*s*. to 4*s*. 6*d*. per dozen; Cauliflowers, 1*s*. 9*d*. to 2*s*. 6*d*. per dozen; Cabbages, 10*d*. to 2*s*. do. *St. John's*.—Potatos, 10*d*. to 1*s*. per peck; do., new, 2*d*. to 6*d*. per pound; Grapes, foreign, 8*d*. to 1*s*. per lb.; Pines, English, 5*s*. to 6*s*. each; Peas, 8*d*. per pound; Cob-nuts, 8*d*. do.; Asparagus, 1*s*. to 1*s*. 3*d*. per bundle; Cucumbers, 5*d*. to 6*d*. each; Mushrooms, 1*s*. 6*d*. per pound, and 1*s*. 6*d*. per basket. *Birkenhead*.—Potatos, 8*d*. to 10*d*. per peck; do., new, 2*d*. to 4*d*. per pound; Peas, 6*d*. do.; Cucumbers, 4*d*. to 8*d*. each; Grapes, English, 2*s*. to 3*s*. 6*d*. per pound; do., foreign, 6*d*. to 10*d*. do.; Mushrooms, 1*s*. to 1*s*. 6*d*. per pound.

CORN.

Average Prices of British Corn (per imperial qr.), for the week ending April 1, and for the corresponding period of 1897, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.		1899.		Difference.	
	s.	d.	s.	d.	s.	d.
Wheat	35	3	24	11	− 10	4
Barley	27	11	26	2	− 1	9
Oats	17	10	16	11	− 0	11

SEEDS.

London: *April* 5.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that to-day's seed market was poorly attended, with but a small business doing. Buyers, just now, are acting with extreme caution, the orders they send up being much smaller than is usual at this stage of the season. Meanwhile, quotations all-round stand at the low level previously noted. Germany is still taking American Red from London. For Tares the sale is slow. There is no important alteration in

Birdseeds, and Mustard and Rape-seed keep firm. Some choice new Scarlet Runners are now obtainable on very tempting terms. Blue Peas and Haricot Beans are held for late rates.

Action of Frost on Leaves of Arum maculatum.—Passing through Knowle Park a few days since, our attention was attracted by the bright yellow tips of the still convolute leaves of Arum maculatum just pushing above ground. On closer examination, it was found that the extreme tips were brown and dry, presumably from the action of frost on the growing point; the upper portion of the leaf below the extreme tip, and about as far back as the middle, was of a rich golden yellow, and the base deep green. It would seem, therefore, that whilst the extreme tip was killed outright, the formation of chlorophyll was arrested in the centre, and the base unhurt by frost, was of its usual rich green colour.

Japanese Plums.—According to a bulletin published by the New York Cornell Station, Mr. L. H. Bailey considers that Japanese Plums are adapted to a much wider range in the United States than are varieties of the domestic type. The Japanese Plums are particularly desirable for earliness, great productiveness, almost complete freedom from black knot and leaf blight, for long keeping qualities, and beauty of fruit. In quality, however, they are inclined to be inferior to the domestic varieties. If for New York late-blooming varieties should be selected, and little damage need then be feared from frost.

More Open Spaces.—Over a hundred years since, in the rear of Guy's Hospital, there existed a "God's Acre" of some repute; it was truly a place for the dead—for the "crunchers" of the period—surrounded, as it was, by open sewers and ditches, this plot fostered disease, and so helped to break down life. To-day it is turned into a place for building up healthy bodies, and every promise given that the rising generation of that ilk shall have in it some of the best thews and sinews on that side of the Thames. Obnoxious as a place for the dead, this spot was transformed into a builders-yard, but it occurring to some that the place was eminently fitted for a recreation-ground, that local authorities and County Council set to work, and on Thursday, March 30, the Nelson Recreation Ground was thrown open amid the cheers of a happy crowd of expectant children. A week or two since, a triangular plot at the junction of Exmouth Street and Rosebery Avenue was given to the locality by the County Council. It was a "remainder over" from a long desired metropolitan improvement, and already gives every evidence of being thoroughly appreciated by those for whom it was set apart.

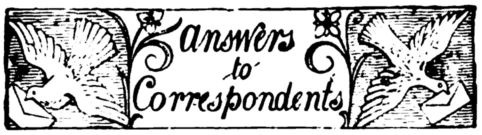
CATALOGUES RECEIVED.

Fredk. W. Kelsey, 150, Broadway, New York, U.S.A.—Hardy Trees and Plants.

W. Goodliffe, M.A., Cambridge Nurseries, Northcourt Road, Worthing—Plants and Bulbs.

J. Cheal & Sons, Lowfield Nurseries, Crawley, Sussex—Dahlias, Chrysanthemums, Carnations, Violas, &c.

J. C. Tissot et Cie., 31, Rue des Bourdonnais, Paris—Horticultural Appliances.



Annuals and Perennials Suitable for a London Garden: *S. S. F.* If the garden enjoys a fair amount of air and sunshine, the following will succeed and afford flowers as long as annual plants endure. Asters in great variety, especially the Crown, Cocardeau, Pæony-flowered, and Truffaut's pyramidal; Zinnias; both tall and drawf; Salpiglossis, Balsams, Celosias in variety, Amaranthus caudatus, Castor-oils, German tenweek, East Lothian intermediate, and numbers of new varieties of Stocks; Sweet Sultan, in three colours; Petunias, Nicotiana affinis, Didiscus cœruleus. The above should be raised in a hot-bed having a night temperature of 60° to 62°, and one by day of 70°, with air afforded. Hardy annuals for sowing on the open border may consist of such of the following as may be suitable to the size of the borders. Acroclinium, double and single flowered vars.; Arabis albida, A. alpina, Bartonia aurea, Brachycome iberidifolia, Calandrinia in var., Calendula officinalis Meteor, Sulphur Crown and others; Coreopsis, many vars., dark crimson, yellow, brown, &c.; Candytuft in var., Lobel's Catchfly, Chrysanthemum carinatum, C. coronatum, C. tricolor, Burridgeianum, and others; Clarkias in var., Collinsias, Dianthus diadematus, D. Heddewigi, and others; Eschscholzia californica, E. crocea, E. Mandarin, &c.; Eutoca viscida, Godetias in var., Lavatera trimestris, Larkspurs in var., Malva moschata, Meconopsis cambrica, Myosotis (Forget-me-not) various; Mignonette in var., Nasturtiums, tall and dwarf; Poppies in much variety, besides perennial species; Sweet Peas, mixed or separate varieties; Tagetes pumila, and T. Golden Ring; Virginian Stock.

Celery for Stewing: *E. H.* The best would be a variety that possessed short, thick sticks, say, Crystal White, Sandringham White, or Col. Clarke's Red. These varieties being comparatively dwarf, can be blanched to their full length in a short space of time after reaching full size. Grow them in rich soil, and never allow it to lack water, and the sticks will be crisp and "short."

Cucumbers: *J. L.* Finding no traces of eelworms on the roots sent, which, on the contrary, were quite normal, we must infer, from the appearance of the fruit, that it is really an instance of "rust." This disfigurement of a Cucumber, or a bunch of Grapes, may be brought about by letting hot vapour impinge on the skin, and also by admitting frosty or very cold currents of air to the forcing-house.

Dendrobiums: *Veritas.* All the Dendrobiums you mention require a high temperature and much moisture from now onward until the growths are completed, especially D. atro-violaceum.

Diseased Cypripedium: *J. D., Tooting.* This is another case of the root-disease of Orchids, referred to in *Gardeners' Chronicle*, April, 1898, p. 206. It also seems similar to specimens sent by you previously, without roots (*Gardeners' Chronicle*, June, 1898, p. 368). The roots have dried up, and no longer do their work. A fungus is present in the outer parts of the root, and it can be traced a short distance into the stems along discoloured tracks. The blackening of the leaves occurs chiefly on the younger ones, and follows the larger veins; this, we think, indicates interference with the water supply, due to death of the roots. The healthy appearance of the older leaves indicates that the plants have started all right, and that the root disease increased in its effects later. The roots need attention, but we do not know of any remedy which will not harm the plants. It is significant that in this and former cases we have seen, only single plants amongst others go wrong; the disease does not seem to be epidemic, yet it is well to isolate plants showing it.

Fern Case: *S. S. F.* The plants which grow with the least amount of trouble to the cultivator are Ferns, and you may also get colour amongst them; but as you desire something more showy, you should grow the ornamental-leaved Begonias, Euonymus japonicus, variegated variety; Vinca elegantissima, Phyllostachys Kumasasa—a dwarf, slender Bamboo; Bambusa pygmæa, and B. tessellata, 1 to 1½ feet; small Golden Privet, &c.

Insects: *R. Mason.* The stick-like caterpillars are those of the Willow Beauty, Boarmia rhomboidaria. They feed on a variety of trees and shrubs. They conceal themselves in any convenient sheltered place during the winter, and commence feeding again with the first warm spring days. As they feed by night, and either lie beneath the branches or stretch themselves straight out from a twig during the day, their presence is usually only detected after some of the leaves have been eaten. The moth is found in June and July.—*R. M. C. J.* We are unable at present to say with any degree of certainty what these eggs are.

Japanese Maples: *A. R.* These are usually worked on stocks of Acer polymorphum, home-raised from stratified seed, or imported as plants. The methods employed are side and whip-grafting. These Maples can also be budded in summer.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—E. J. H.* Ceanothus rigidus, *Bot. Mag.*, t. 4664.—*G. H.* Please address such communications in future to the Editor. It is not an advertisement. 1, Cupressus Lawsoniana, erect variety; 2, Thuya occidentalis var.; 3, Libocedrus decurrens; 4, Thuya occidentalis; 5, Thuya orientalis var.; 6, 6, Tsuga Sieboldi.—*J. R.* 1, appears to be Cœlogyne cristata, Chatsworth variety; 2, C. c. Lemoniana, or that variety of it called intermedia in some gardens.—*J. P. D.* 1, Cattleya labiata Luddemanniana; 2 and 3, forms of Cattleya labiata Schroderæ.—*J. D. A., Suffolk.* 1, Dendrobium aggregatum; 2, Dendrobium chrysotoxum; 3, not found; 4, Dendrobium Pierardi; 5, Dendrobium fimbriatum oculatum. —*W. T.* A very pretty variety of Odontoglossum × Wilckeanum, a natural hybrid between O. crispum and O. luteo-purpureum. You are very fortunate to secure it among imported O. crispum. —*One in Doubt.* 1, Libonia floribunda; 2, Acacia armata; 3, send when in flower; 4, Dioscorea illustrata; 5, Datura species, send when in flower; 6, Pilea muscosa.

Orchids, Various: *Orchid.* The Odontoglossum Hallii xanthoglossum is a good variety; the spotted O. crispum a remarkable variety, worthy of care; Dendrobium flowers are rather small, but the number of blooms on the pseudo-bulb may account for that. If the Dendrobium nobile sent as nobilius is true, it is not grown to perfection. The flowers of Lycaste Skinneri are good, and represent distinct varieties. The Dendrobium, suggested to be D. Griffithianum, seems to be D. chrysotoxum. The others are all good of their kind.

Potted Peach-trees Casting their Leaf-buds: *C. N. M.* The deprivation of the trees of the accustomed open-air moisture since they were placed under glass, or dryness of the soil from insufficient application of water, may be contributing causes. The balls should be turned out and examined, and if they are found to be dry, it would be prudent to return them to the pots, and immerse the latter in water for a quarter of an hour. Loamy, firm soil, when once it has got into a dry state, is difficult to moisten without immersion.

Vine Splitting: *T. N.* The heat from the kitchen chimney may have dried up the lately-planted Vine, and the splitting is due to that cause. It is probably past recovery.

Wellingtonia: *G. H.* Without knowing more as to the local conditions, subsoil, drainage, &c., we cannot tell what is amiss with your trees. We find neither insect nor fungus on the specimen sent. The ill-health of the trees may be due to a water-logged soil, to injurious substances in excess in the soil, or to its poverty. If the first, draining off the surplus water by means of ditches, 3 to 4 feet deep, made at 25 to 35 feet apart, or covered drains of that depth consisting of 1 to 1½ feet of stones covered with first, sods, and then the staple. If it is the last, poverty of the soil, it can be improved with leaf-mould, loam, and decayed peat, applied as a top dressing over the roots.

THE
Gardeners' Chronicle
No. 642.—SATURDAY, APRIL 15, 1899.

THE GARDEN AT HOLLAND HOUSE.

THIS, the home of the present Lord Ilchester, of the famous Lady Holland of illustrious memory, and of a number of persons distinguished in our annals, stands in a park of about 200 acres, situated between the Uxbridge Road on the north, and Kensington High Road on the south. The mansion stands on elevated ground some 400 yards distant from the latter road. The builder has been busy on the west and east sides, but this notwithstanding, the privacy of the grounds is well maintained by the close screen of ancient Elms and other large trees which form the boundary, and which on the eastern side assume the form of an avenue to the approach-road from the entrance-lodge to the mansion. In the immediate neighbourhood of the latter the trees form almost a wood, and the seclusion is perfect. It may be remarked by the visitor that provision is continually being made for the future by the planting of suitable trees of large growth wherever there is a chance of their succeeding.

We extract from an account of Holland House that appeared in these pages in the issue of July 5, 1881, from the pen of that pleasant writer, the late H. Evershed, the following particulars :—

"The original manor of the De Veres consisted of 500 acres, but more than three-fifths of this wide space have now been built upon. The site of Little Holland House, worth £20,000 per acre, has been long since devoted to the crop which at Kensington exceeds all others in profit. The area of the kitchen garden between the house and Addison Road has been considerably diminished by the erection of a good house, called Oak Lodge, whose ample and ornamental grounds occupy, it is said, the site of the old Manor House, with its moats, or studponds, and of the monastery. The name Addison Road speaks for itself. That of Melbury Road was derived from the name of Lord Ilchester's chief seat in Dorsetshire."

Lord Ilchester is a descendant of the eldest son of the founder of the Fox family. The house forms a square block, and the south is the best side, being relieved with wings and arcades. The walls of the house in some parts are beautified by a chequer work of terra-cotta plaques. The area, about half an acre immediately in the front of the south side, originally sloped, as does the rest of the land on that side to the Kensington road, has been raised to a dead level by building a retaining wall some 40 yards distant from the house, the enclosed space being ornately treated, and the wall embellished by Roses and climbing plants in variety. Fig. 85, p. 227, shows the house on the west side.

The Dutch garden on the west side (fig. 86, p. 229) consists of an intricate design of flower-beds and scroll-work in Box. The Box-plants are said by Mr. Dixon, the present head-gardener, not to have been relaid for 100 years, although "mending" is occasionally found to be necessary. What edging, therefore, can be better than Box for a London garden? The high brick wall on the north side of this garden was once covered with Plum, Peach, and Nectarine trees, which, when the air was less smoke-laden, doubtless brought their fruits to perfection. In front of this sunny wall the poet Rogers loved to stroll.

The poet and the fruit-trees are now but a memory, and in the place of the latter we found a number of uncommon flowering creepers, more perhaps in keeping with modern ideas of appropriateness. It will suffice to mention a few of these exotics that endure our London climate, and withstand our hard winters. Physianthus (Arauja) albens grows freely and bears fruit; the Oriental Laburnum, Piptanthus nepalensis, and Olearia Haasti flower profusely, as they do everywhere in the London district ; Vitis orientalis, a species with foliage very handsome in its autumn garb ; V. purpurea, equally desirable as a plant for covering a wall or an arbour ; Akebia quinata, with its quaint, purple-brown flowers ; Ceanothus Gloire de Versailles, one of the best, and fairly hardy under slight protection ; C. Marie Lemoine, a quite hardy variety, with pinkish flowers ; Solanum jasminoides, which most persons cultivate in the greenhouse, flowers freely, although in some winters it gets cut, but is never killed ; a variegated form of the Japan Hop-plant, pretty as a variety ; Ware's hybrid Passiflora cœrulea, differing but little, if at all, from the type ; that old but recently resuscitated Passiflora Constace Elliott, which has white flowers, and Mühlenbeckia complexa, a shrub that forms a tangle of black wire-like branches, and has small orbicular leaves, grows freely, notwithstanding the fact that it suffers in severe winters. A most interesting wall. There are many other plants tentatively planted, of which it is yet too early to say much.

The bedding-plants in the Dutch parterre bespoke a love for the old rather than a preference for the modern finer varieties of things, and this did not seem at all inharmonious where all around is associated with the past. The beds just under the windows overlooking this garden were laced over with low festoons of Virginian Creeper—a quaint and pleasing idea.

Close by, a doorway in the creeper-covered wall admitted us to the north lawn—a charming space with a surface velvet-like and closely shorn, and dotted at the margins with big trees, and which, moreover, is not disfigured by any walks ; in fact, there was none, excepting that which skirts the mansion. What a treat to the pedestrian used to rustic ways and green fields, who is condemned to tread the stony streets of the metropolis. At a distance of about 80 yards from the wall afore-mentioned, there begins a series of long beds cut in the turf, and spread out like one's fingers, the turfen walks between them being of a good width. This arrangement is the very antithesis of the Dutch garden.

The beds are furnished with herbaceous perennials, hardy bulbs, including many species of Lilium, varieties of Roses, &c. Colonies of one plant are preferred to small patches or groups, and sometimes entire beds are filled with one species, whilst others have several ; in fact there reigns throughout a sort of orderly confusion, the needs of each kind of plant receiving suitable recognition ; and the plan being carried out on a big scale, the effects in the spring, summer, and autumn, must be very satisfying.

Of beds planted with one or two species of plants, some were noted in which were Bamboos, Epimediums, Lilium croceum, and L. dahuricum ; golden-leaved Japanese Privet, and Prunus Pissardi ; Roses, Caroline Testout and La France, and the red variety of the latter called "of 1889," which succeeds capitally ; and Cistus Florentinus, which is quite hardy here, whilst other species of Cistus are not, forms good-sized shrubs. There were beds of Comptonia asplenifolia—a nice shrub ; of M. Lemoine's new varieties of Philadelphus (Syringa) ; of Alstrœmerias in different species, which are employed in conjunction with Lilies, the flowering of the former forming a succession to the latter. This struck us as being a happy combination, and the planting once properly done, no disturbance of the bed is needed for several years—in fact, is undesirable. A border of mixed varieties of the Rose is backed with plants of Helianthus flore-pleno Soleil d'Or, the Roses consisting of Teas, H. P.'s, and others.

The avenues of certain kinds of plants form a novel feature : for instance, there is one of Weigelas ; another of the newest and best varieties of scarlet-flowered Thorns ; another of Pavias, and yet another of Mock Orange (Philadelphus), and so on. It would appear that more of this sort of planting is contemplated. The method of treatment is as follows : a piece of hitherto wild ground is skimmed of the turf, which is stacked on an adjacent spot, so as to be handy for use when decayed. The land is then well manured and dug, and seeds of Poppies and the common Foxglove are sown together. The Poppies bloom the first, and the Foxgloves the next and the third year. The land is at the end of this term again dug and planted with shrubs, or with Narcissus and other hardy bulbs, and permitted to assume its original wild character as before. Sometimes, at this stage, various British plants are set out, as Epilobium, &c., and allowed to take possession of the land. Nothing is kept too trim in these patches, the charm of semi-wildness being constantly borne in mind.

We observed Lilies, Gladiolus, Iris Kæmpferi, Delphinium, and Galtonia (Hyacinthus) candicans, planted by the hundred ; also beds of mixed species of Lilium, those of the old world being exclusively chosen, as Californian species refuse to thrive. These Lily-beds have superficies of 100 to 150 square yards apiece.

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

IRIS TUBERGENIANA, *Sp. n.*

I HAVE received from the firm of C. G. Van Tubergen, Junr., a little Iris, whose characters seem to justify specific distinction. It is allied to I. caucasica and I. orchioides, but differs from both. Bulb somewhat slender, with the ordinary characters of a bulb of a Juno Iris. Plant about 10 cm. high at flowering time, with one, two, or more apparently sessile flowers. Leaves about six, each 6 to 8 cm. by 1 to 5 cm. at broadest, light glaucous green, pointed, conspicuously striated, and with a marked "cartilaginous" margin. Spathe valves 4 or 5 cm. long, narrow pointed, not inflated, thin, but-green, membranous at tip only. Fall about 4 cm. long, rather more than 1 cm. at its broadest part. The claw bears lateral expansions, so that the whole fall is more or less fiddle-shaped. The fall possesses a median crest, which along some distance back from the extreme front is cut up into conspicuous filaments, 1 cm., or nearly so, in length, so that the crest becomes a linear beard. Standards minute, three-toothed, the median tooth being usually longest, stretched out horizontally. Style nearly 3 cm. long by about 1 cm. broad, with a conspicuous tongue-shaped stigma, and two large deltoid crests.

*

Anthers large, pollen coarse and abundant. Ovary, rounded trigonal, rather more than 1 cm. long; tube, three or more times as long as the ovary. The falls are bright yellow, especially the crest and beard, but with a slight tinge of green. As in I. orchioides, the blade of the fall is marked by a few scarce variable blackish-green streaks or dots. The styles are of a more distinctly greenish-yellow. The plant, without being exceedingly handsome, is pleasing; flowering, as it does, nearly at the same time as the purple Iris reticulata, it supplies an agreeable contrast to these. In foliage and habit it resembles I. caucasica, though the leaves are more glaucous, and more distinctly striated. The flower is like that of orchioides, but differs in the claw having distinct lateral expansions (these are wholly absent in orchioides), and in the crest, which in orchioides is often hardly even serrate (in caucasica it is often very serrate), being cut up into a conspicuous linear beard. The two features seem to justify its being regarded as a distinct species. The conversion of the crest into a beard, though useful in this case for specific distinction, is one of many instances showing how little value can be attached to the possession or lack of a beard or crest as a fundamental character, and so a means of forming large groups of Irises.

Diagnosis.—General features of the bulb of the various parts of the plant that of a Juno Iris. Foliage, habit, and general features, exclusive of the flower, the same as in I. caucasica. Flower resembles colour and otherwise that of I. orchioides, except that the claw of the fall bears conspicuous lateral expansions, and the median crest of the fall is cut up into a conspicuous linear beard.

* * * *

I have also received, through the kindness of the same firm, two new hybrid Irises of their own raising.

One I. sindjarensis × I. persica, is a most charming plant, in foliage and flower almost halfway between the two parents. The flower has a fuller colour than the seed-bearing parent, I. sindjarensis, though it has not the conspicuous colour patch at the apex of the fall, which is so marked a colour feature of the pollen-bearing parent, I. persica. The plant is quite dwarf, and exceedingly floriferous. Every one who sees it will, I am sure, want to possess it.

The other is a cross between I. persica type, and I. persica purpurea. It, too, is almost halfway between its parents, and though the purple is of a somewhat lurid hue, the plant is very charming. Both of them, especially the former, supply a welcome addition to the garden. *M. Foster, Great Shelford, March 29.*

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM INSIGNE LUCIANI.

Clear yellow forms of Cypripedium insigne are much prized, and one of the best of these is C. i. Luciani, a fine flower of which is sent by A. Warburton, Esq., Vine House, Haslingden. The plant will, doubtless, be known to some cultivators by the fine figure in *Lindenia*, xi., p. 53, but the illustration is surpassed by the flower sent by Mr. Warburton, notably by bright yellow taking the place of the green base of the upper sepal. The flower is of an uniform deep chrome colour, except the upper half and margin of the dorsal sepal, which are pure white. A striking feature in the flower is the broad, well-displayed petals.

Yellow Cypripedium insigne are always associated with the famous C. i. Sanderæ, which, when seen at its best, is still the finest variety. Latterly some orchidists report that even this fine form varies not only in the size, but somewhat in the form of the flowers of the same plant at different times, and that lately it has displayed a tendency to produce a few slightly-raised dull purple-brown spots on the yellow of the lower part of the dorsal sepal. A flower of it sent by Mr. Warburton also displays this peculiarity. The plant was said to have been grown in a cold-house. Probably, if assisted with a little more warmth when perfecting and expanding the flowers, the markings, which are viewed in the light of a blemish, would not be developed.

ODONTOGLOSSUM LUTEO-PURPUREUM VUYLSTEKEANUM.

It is always a pleasure to meet with any of the well-marked, rare varieties of Orchids of which but few examples exist, as it proves that the cultivator knows how to deal with them, and to increase their number. A case in point is furnished by the Rev. F. Paynter, Stoke Hill, Guildford (gr., Mr. Cook), who has sent us a fine inflorescence of that remarkable variation in typical O. luteo-purpureum, in which the brown markings are absent, and the whole flower, except the cream-white front lobe of the lip, is pale yellow, with bright orange markings. It puzzled Reichenbach so much, that in the *Gardeners' Chronicle*, 1884, p. 7, he described it is a species under the name of O. Vuylstekeanum, remarking on certain resemblances to O. × Wilckeanum and O. × mulus, which certainly do present themselves, especially in the hawthorn scent of the flower, similar to that noticed in O. mulus. There seems little doubt, however, that it is a seedling sport typical in O. luteo-purpureum, in which the darker colour has been suppressed, leaving a clear yellow flower of two tints, in the same manner that O. l.-p. Masereelianum is transfigured in the O. l.-p. sceptrum class. The whole contour of the flowers, with their spiny crest and broad, crimped, and fringed labellum, makes it a very attractive plant, and its rarity makes it valuable. Forms of O. luteo-purpureum are gaining in favour, and varieties that are beyond average quality fetch high prices.

DENDROBIUM NOBILE SCHRODERIANUM.

This is the largest flowered and most beautiful white D. nobile. In the collection of the late Mr. Gair, of Falkirk, there appeared a similar variety, and flowers of it have been sent us by Mr. Mark Watts, Selwood Gardens, Rotherham, the home of the now distributed Owen collection. D. nobile candidulum figured in *Lindenia*, x., p. 99, is an ally, but with lighter purple base to the lip.

CONIFERS.*

Culture.—From their wide range of distribution, and from being found chiefly in elevated situations where the air is pure, we may deduce two important facts as guides to their successful culture. First, Coniferæ are not over fastidious as to soil; secondly, to flourish they require pure air. Such indeed is the case. Coniferæ generally will grow in almost any kind of soil, provided they receive the requisite amount of moisture; but they flourish in a cool rich sandy loam. These facts are strikingly exemplified by Pinus sylvestris which, as we all know, will grow almost anywhere. It flourishes on sandy loam in the plains, and on mountains of granite and gneiss as in Scotland. On hard-binding soils it is more subject to fungoid diseases; on stiff loam its height suffers; on shallow rocky soil (limestone and chalk) there is a decided tendency towards the malformation of the bole, and it is also dwarfed and short-lived. Other species have peculiarities in habitat, &c., which may be interesting to note:—Pinus Pinaster seems partial to the low, swampy, and salty districts near the sea-shore. P. halepensis, unlike its congeners, appears partial to limestone, though it is not absolutely confined thereto. P. australis and P. Tæda abound on the sterile sand of the famous "Pine barrens" of North America. Larch grows rapidly on the chalk, but does not stand. Golden Yews revel in a clayey soil and shady position. Taxedium distichum should be planted near water. Lastly, for Araucarias and Retinospora section of Cupressus, a light sandy loam is absolutely essential. The abuse of the second "great factor" of success (i.e. pure air), is unfortunately only two well shown by our Conifers at Kew. This, together with the drought in summer, is undoubtedly the cause of our partial failure to grow them.

Conifers may be planted to serve many purposes. For ornamental effect, they stand second to none, either as specimens on lawns, or in groups, or mixed with dicotyledonous trees, anyhow or anywhere, they "head the poll." At Kew, although we cannot boast of specimen Conifers in the sense that Dropmore, Penrhyn Castle, or Hewell Grange can, nevertheless, some of ours give a tolerably good idea of what they can be. Look at the noble aspect of that clump of Cedars over-shadowing the "Temple of Sun," and of the vista of Cedrus atlantica, leading to the Pagoda; or again, the stately grandeur of some of our specimens of Pines, Cedars, &c., such, for instance, as Pinus Laricio, P. pinea, P. Coulteri, Cedrus Lebani, Ginkgo biloba, &c. Furthermore, a visit to our temperate-house will not fail to convince anyone of their value for conservatory decoration, particularly Araucarias and Dacrydiums, which are not quite hardy in this country.

Apart from their ornamental qualities, the larger growing genera (Pinus, Abies, Picea, Tsuga, &c.), are specially adapted for planting as "nurses" to more tender trees (fruit, &c.). Their dense habit, and persistent leafage, is an effectual barrier against the cold, biting east winds, so destructive to fruit trees in spring.

Again, these same large-growing species are indispensable for economic planting in the formation of woods and forests. The veriest tyro is familiar with "Deal" and "Pitch Pine," two of their forms of timber.

Planting may be conducted from the beginning of September to the end of March, weather permitting. In planting Conifers, and, indeed, all trees and shrubs, make the holes sufficiently large so as to admit of spreading the roots out all round. It is a bad beginning to cramp the roots up anyhow at the outset—give them room. Plant firmly, but not too deeply. A barrowload of rough loam in the bottom of the hole, and a little spread over the roots, is excellent medicine, but avoid rank manure in planting. Those needing it should be staked at once, or the wind may damage them. A mulch of litter or lawn-mowings is very beneficial in summer, especially to freshly-planted plants.

After they have become established their wants are few, merely the ordinary attention of arboriculture, that is, the keeping free of choking weeds, the cutting away of dead branches, and the trimming into shape of those for ornamental purposes. If branches of considerable size are removed, a coating of tar should be applied to the wound, as this checks "bleeding," and also prevents decay from water soaking in. The "leaders," too, should be looked after and kept straight, tying to a stake. Sometimes they lose their "leaders," either by accident or otherwise, as is the case with some Abies and Piceas in the Kew collection (A. nobilis, A. concolor). In these cases, the topmost lateral should be tied up to replace the main axis. With the pyramidal-growing species (Irish Yew, species of Thuya, Cupressus, Juniperus, &c.), it is a good plan, where practicable, to go round, after a snowstorm and tap them with sticks to dislodge the snow, this preventing their being broken down by its weight. Lastly, and most important of all, Conifers must never be allowed to suffer from want of water; when freshly planted, this item must have special attention—if once they suffer, they are crippled, if not killed outright.

PROPAGATION.

This may be effected by seeds, grafting, cuttings, or layering—but the first, the natural method, is by far the best; nevertheless, for the variegated forms of certain species, the latter methods are the only reliable means of perpetuating the variety.

---

* Extracts from a paper read before the Mutual Improvement Society of the Royal Gardens, Kew, by Mr. E. H. Wilson. The Hooker Prize was awarded to this essay.

Seeds. — The majority of Coniferæ bear seed readily when they arrive at maturity. The seeds are borne in cones, which vary in size from that of a child's head (Araucaria Bidwelli) to a little larger than a good-sized Pea (Cupressus sp.). Generally, by their hygroscopic character, the cones, when ripe, liberate their seeds, and then fall away. The seeds are frequently winged, and this assists in their dispersal by the wind. In Pinus muricata the cones remain attached for many years; this is well shown by specimens in the Kew collection, some of which must be twenty years old.

To obtain seeds for sowing, the cones should be gathered as soon as ripe (or just previous), and placed in a warm dry place. The scales will then separate, and the seeds fall out. The cones of the Firs release their seeds more readily than do many species of Pines (P. pinea, P. Pinaster, &c.), and these should be exposed either to solar heat or to gentle warmth given by oven or kiln. A good and simple method is, in February, to bury the cones a couple of feet in sand, and in a month or six weeks' time the scales will easily fall away; the seeds having swollen must be sown at once. The cones of Cedars are very resinous, and ought to be kept a year before the seeds are separated, in which time the resin will have partially evaporated.

March or April are the best months for sowing the seeds. Seed-beds should be prepared in a shady part of the garden, using a compost of light sandy loam and leaf soil. Make the beds level and rather firm; scatter the seeds thinly and evenly over the bed, and then lightly cover with sandy soil. These beds must not suffer for lack of water. Under such conditions as these, most of the hardy varieties will germinate in eight to twelve weeks from time of sowing, though occasionally some (species of Cupressus and Juniperus) may even take two years to germinate.

The seeds of all the more tender Conifers (Araucarias, Dacrydium, Podocarpus, Widdringtonia, &c.), must of course be sown in heat. Sow in pans or boxes in sandy soil, and place in bottom-heat of about 70° F. When large enough, prick off, and grow on in heat, and finally harden off into a cool-house. For the first two years of their life, Conifer seedlings develop very slowly. It is not until the third or fourth year that they "push." When about 2 inches high, the seedlings in the beds outside should be pricked off into other similarly prepared beds. In winter a "light" (glass), or a few pieces of Yew or Pine-branches stuck amongst them, will break the force of the cold biting north and east winds.

One of the most important items in Conifer-culture is transplanting. On the regularity with which this is performed, much of the future success depends. No Conifer, seedling or cutting, should remain in one position longer than two years, until it can be planted in its final position. Transplanting promotes the development of a mass of fibrous roots. Of course, if a seedling can be planted permanently at onset, so much the better; but this is rarely practicable save in forests. A very striking and remarkable fact is the diversity in form, &c., presented by a bed of Conifers, so much so, that it is often impossible to tell what they are until they are four or five years old. We ourselves have seen seedlings of Abies nobilis looking identical with those of A. concolor, and those of A. concolor apparently identical with those of A. brachyphylla. Again, some of these "seedling forms" often vary so greatly that if their origin were unknown they could be taken for new and distinct species; as examples of this, we have the "Irish Yew," "Erect Lawson," and "Whip-cord Arbor-vitæ," which are only seminal varieties of the common types. Mr. Harry Veitch contends, and it is generally accepted, that all the varieties of Retinospora have sprung from two types — Retinospora (Cupressus) obtusa and R. pisifera. Indeed, I think we may justly say with Dr. Masters, that "the unexplained phenomenon 'polymorphism' is greater in Conifer seedlings than in any group of plants, and perhaps the Cupressus family show it most." *E. H. Wilson.*

(*To be continued.*)

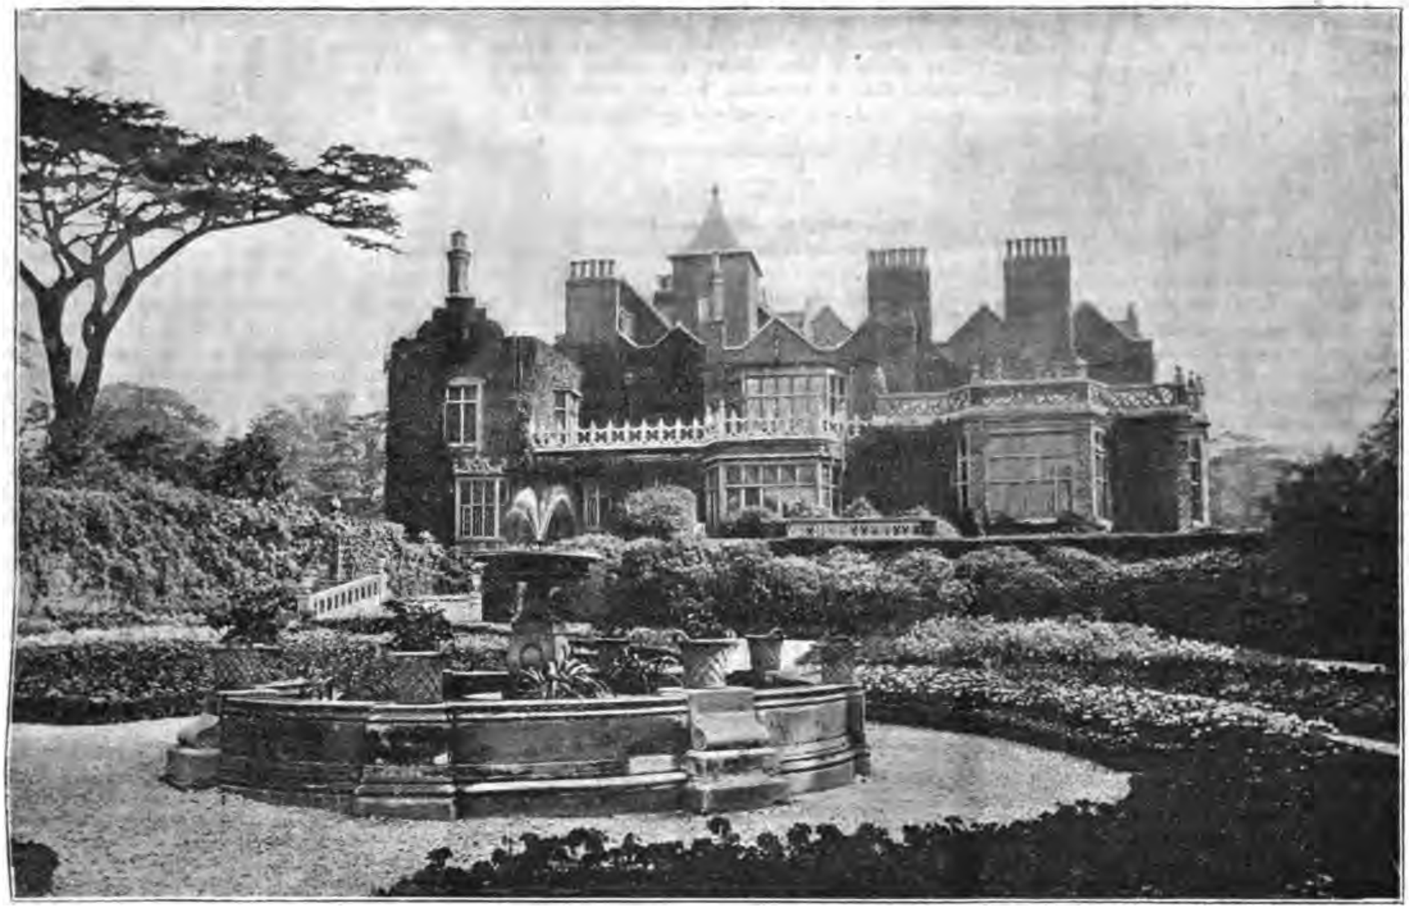

Fig. 85.—Holland House: west front. (See p. 225.)

THE HEPATICA.

(*Continued from p.* 178.)

The double white Hepatica has been a coveted plant, and its existence or non-existence has caused much inquiry and controversy. If we are to believe Ray and Gilbert, it existed in their day, although later Philip Miller wrote in terms which appeared to cast doubt upon their statements. Yet one is disposed to accept the description given by Gilbert of the double white Hepatica in his *Vade Mecum* as true.

A number of years ago a plant of the double blue variety gave an offset with double white flowers in the garden of Mr. W. B. Boyd, of Faldonside, Melrose. Three or four flowers which it produced were taken off and shown to the late Mr. McNab, Curator of the Edinburgh Botanic

Gardens, who remarked, "Well, I have often heard of a double white Hepatica, but I never saw one before." This offset was taken off, but unfortunately too much care was taken of it by covering it with a bell-glass, and it died. In 1893, the manager of the herbaceous department in a North of England Nursery, and in whose veracity I have every confidence, told me that he had seen the double white Hepatica about twenty years before, and that it was in a garden in Perthshire, and also in that of Van Houtte, in Ghent. Three or four years ago (unfortunately, I have not kept a note of the date), it appeared from the replies to correspondents in the *Gardeners' Chronicle* that a flower of the double white Hepatica had been sent for the inspection of the Editor. It had come from Germany, and, after putting myself in communication with the raiser, who was a nurseryman, I learned that it was a seedling, and that plants were not yet ready for sale, although inserted in his catalogue unpriced. There is no valid reason why this double variety should not be recognised as having been in existence, and none exists to prevent us from hoping that the raising of seedlings may give us white, pink, and blue varieties, with intermediate shades, hitherto unknown, of double-flowered Hepaticas.

There is plenty of variety among the single-flowered Hepaticas. We have the common blue; Barlowi, which some have reckoned a species, of a deep purple-blue; single red, single-pink, single white or alba; the same with white anthers, alba major; alba cœrulea, tinged with blue; alba rosea, white, tinged flesh colour; Beauty, silver-grey; cœrulea pallida, with its variety major, pale blue; lilacina, lilac; lilacina pallida; rosea pallida, pale rose; rosea splendens, a fine-coloured flower, with rosy-crimson blooms. One might in time raise all these varieties from seed. The seeds should be carefully gathered as soon as ripe. They may either be sown when ripe, or kept until autumn. The seeds ought to be sown in pans or boxes. The surface of the soil should be kept uniformly moist until the seeds germinate the following year. In order to secure this, some growers place pieces of slate on the top of the pan. When the seedlings are large enough to handle they may be planted out. They will flower in from two to three years after their first appearance.

Fine as is Anemone (Hepatica) angulosa, its sparseness of flower with the great majority of growers militates greatly against its usefulness. In few gardens does it produce anything like a full quantity of bloom, and the writer has seen various methods tried to make it more floriferous, but in vain. Not unlikely we may have to look to seedling-raising to give us free-blooming varieties of this splendid large-flowered Hepatica. In the cultivation of the Hepatica one finds that a good, rather heavy soil is the best for inducing free growth with plenty of flower. A little shade is beneficial; and, provided that shelter from the trying east winds is secured, an easterly exposure suits the plant well. Removal and division ought, as far as possible, to be avoided. It dislikes both; and when it is necessary to divide plants, the soil should be well washed from among the roots before division. Before re-planting, the roots may be dipped in water, and then into dry earth or sand, which will then adhere to the rootlets, which seem shy to take hold of new soil. A little attention to the Hepaticas, in the way of top-dressing with well-decayed cow-manure, will not be unrewarded.

Varieties of Hepatica angulosa.

One is pleased to see that decided breaks in the colouring of Hepatica angulosa have at last been obtained. I am indebted to Messrs. Richard Smith & Co., of Worcester, for bunches of flowers of two varieties of this Hepatica; these were raised at their nursery. The first is named H. angulosa atrocœrulea; it has very large flowers, of deep purple-blue, rather lighter than those of H. triloba Barlowi; this is a very beautiful variety. The other is as yet only named "variety." The flowers are a very delicate pale blue, not so large as atrocœrulea, but with an additional number of sepals. One is at a loss to say which of the two is the more beautiful. Now that we have secured breaks like these, we may expect other tints and shades to be produced in this fine Hepatica. Among the varieties of H. triloba which came at the same time was one I had not seen before, which is, perhaps, more curious than beautiful. It is named tesselata. The flowers are small, and the sepals are not quite as long as the bracts, so that the blooms look as if they were surrounded by a small green collar. *S. Arnott.*

Eranthis cilicicus.

Among other interesting things in the notes on spring flowers by Dr. Dammer, in the *Gardeners' Chronicle* of April 1, is a reference to Eranthis cilicicus. With me it blooms later than E. hyemalis, so that either the climate at Berlin is the cause of the difference, or the tubers have been collected in a different quarter. Personally, I prefer our old acquaintance, E. hyemalis, but some may like the newer introduction better. As Dr. Dammer says, the leaves of E. cilicicus are more finely divided. The plants I have grown are a little darker in colour than E. hyemalis, but my stock has been small. *S. Arnott, Carsethorn-by-Dumfries, N.B.*

KEW NOTES.

Cliveia miniata citrina.—This well-marked, beautiful variety is now in flower in the T range at Kew. It is said to have been collected wild in Zululand by Captain Mansell, and first flowered in the garden of Mrs. Powys Rogers, Perrenwell, Cornwall, in April, 1897, when flowers of it, and subsequently a little plant, were sent to Kew. An example of the same variety had, however, already been added to the Kew collection by the Rev. W. H. Bowden, Bow, North Devon, who sent it along with some other plants which had been collected in Zululand, and it is this plant which is now in flower. It resembles a good form of the type in every particular except colour, in which it differs widely from all the forms hitherto raised in gardens, and popularly known as Imantophyllums. These are all more or less of a reddish orange colour, but the variety citrina is coloured a clear pale cream with a faint tinge of orange at the base of the segments. This variety ought to prove valuable to breeders of Cliveias, whose efforts so far have produced exceptionally little colour variation in the seedlings raised.

Hæmanthus cinnabarinus.

A group of about twenty plants of this handsome Hæmanthus is now flowering in the Nepenthes-house at Kew, where, owing to the conditions being favourable, the leaves and flowers are of much larger dimensions than those represented in the *Botanical Magazine,* t. 5314; indeed, the Kew plants might be taken for H. Lindeni, which differs from H. cinnabarinus only in the larger size of its leaves, and greater number of flowers in the umbel. H. cinnabarinus was introduced from the Gaboon in 1857, and has since been found in other parts of the Guinea coast. The Kew plants now flowering were brought from Aburi, Gold Coast, by Mr. C. H. Humphries nearly two years ago. Planted in light soil in the low rockery in the Nepenthes-house, this bulb has grown much more satisfactorily than others of the same species which were started at the same time in pots. The flowers are of a bright cinnabar-red colour, and they are arranged in a large head, as in Agapanthus.

Erica Chamissonis.

This Cape Heath is so similar to that shown by Messrs. Veitch as E. propendens at the Drill Hall recently, that it might easily be mistaken for it. There are good botanical differences, however, in the length of the pedicels and the colours of the anthers, which in E. Chamissonis are of a bright purple colour, and the pedicels are half an inch long; whereas in E. propendens the flowers are sessile on the ends of the branchlets. In habit and colour there is practically no difference, and for garden purposes they may be said to be of equal value. That E. propendens has merit was proved by the award of a First-class Certificate to the plants shown by Messrs. Veitch. E. Chamissonis was figured in the *Botanical Magazine* in 1874 (colour too pink), when Sir Joseph Hooker bewailed the disappearance of the beautiful Cape Heaths from English gardens, attributing it partly to their culture being unknown to most gardeners of the present day, who kill such plants with too much water. Such pretty greenhouse plants as the two above named are worth the little special attention they require, even in these days of hurry from seed-pot to exhibition hall. *W. W.*

IRELAND.

DUBLIN.

We had the best spring show we ever had here on Thursday last, April 6. Daffodils, Cyclamens, Arum Lilies, and Freesias as good, or even better than I ever saw them before. Fruit and vegetables also very fine; Royal Sovereign Strawberries, Cox's Orange Apple, Catillac Pear, obtained 1st prizes. Orchids and stove plants, especially Crotons (Codiæum), were very rich in colour. Flowering shrubs, Deutzias, Azaleas, and herbaceous collections, shrubs and bulbs included, were superb.

The finest sight in Dublin streets to-day is Sir Philip Crampton's Pear-tree, a Jargonelle, planted by him in the area in front of No. 14, Merrion Square, N., in the year of our Lord, and of Waterloo, 1815. It is now one vast sheet of white clustered blossoms, resembling wedding bouquets, and the admiration of the most *blasé* or *borné* passer-by. Even the car-men point at it with their whips as they drive past, and say to their "fares," or to each other, "Look at that for Oireland! It's moighty fine entirely. So it is, begorrogh!" I have never seen a single fruit-tree so fine and fertile anywhere, and we look upon it here as quite a historical and national monument to one of Ireland's many great medical or surgical men.

The gales have blown our Daffodils to pieces; they did not "dance with glee," nor did our "hearts with pleasure fill;" we deplored the ruin, and hoped for more genial April days. *F. W. Burbidge.*

CULTURAL MEMORANDA.

GOLDFUSSIA ANISOPHYLLA.

Some score of years ago this pretty plant was frequently seen in gardens, but for some reason it has now almost disappeared. The plant is an evergreen, with dark green leaves and tubular flowers of blue and lilac colours, borne in profusion. Flowers of these tints are not plentiful among stove plants in the summer and autumn months: and having regard to this fact and to the ease with which they can be produced, the plant deserves a place in every garden. After flowering, a plant should be cut back and afforded a partial rest, i.e., water should be withheld for a few weeks, not, however, allowing the mould to become excessively dry. When the plant breaks, partially shake the roots of the soil, and repot in a pot of a suitable size (say a 6 or an 8-inch one), using a compost of equal parts fibry loam, peat, or decayed cow-dung, broken up by hand, and some silver-sand. During the growing season afford the plant a temperature of 65° to 80°, and abundance of aërial moisture. The plant being always infested with red-spider in a dry house, it is very essential that it be kept in a moist one till it begins to flower, when a drier one is more desirable. As it flowers in the summer and autumn, a warm conservatory will suit the plant at that time, being conducive to continued flowering and the ripening of the wood, not only of this plant but most stove plants during those seasons.

Young unflowered shoots 3 inches in length make good cuttings, and these root readily when inserted in sandy soil, and plunged in a hot-bed. When rooted, pot off immediately, growing them on in a stove, pinching out the points of the shoots several times in order to get plenty of branches. *H. T. M., Stoneleigh Abbey Gardens.*

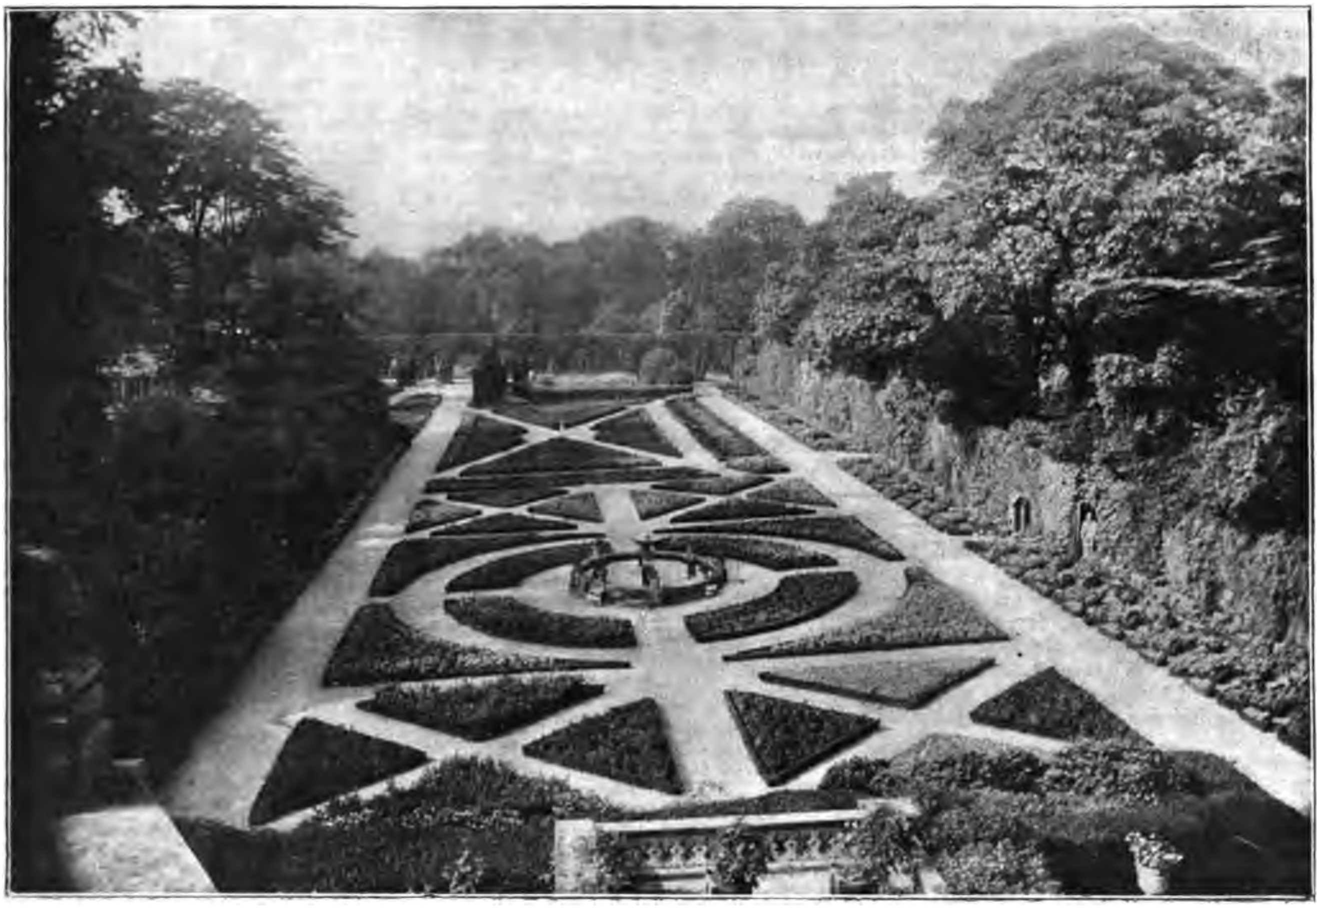

Fig. 86.—Holland House: the Dutch flower garden, looking west. (See p. 225.)

NOTES FROM A SCOTTISH MANSE.

Nature has of late been very capricious and unreliable, so far as regards her atmospheric manifestations. For a time she was unusually mild and gracious in her moods, smiling upon her vernal creations with a summer-like amiability; then suddenly she assumed a sterner aspect, and the progress of vegetation soon received an unwonted check, through a somewhat severe visitation of the frost. In some regions, I doubt not, the results were disastrous; here, where we have a sheltered situation, especially from the north and east winds, whose influence of late has been most severe, we have not suffered much. Heavy rains have followed the departure of the frost, and genial weather once more prevails. Many of my finest Rose-trees have already been generating exquisitely-coloured shoots, especially such varieties as Alister Stella Gray, supposed to be a kind of miniature variation from Wm. Allen Richardson (which here achieves little during the summer, but is on the other hand, a very profuse autumnal bloomer); Madame Pierre Cochet, A. K. Williams, Homer, Clio, and Viscountess Folkestone. Flower-buds are already visible on the Rose last mentioned, which is one of the most precious, alike for beauty and fragrance, of the hybrid Teas. Whether they will be graciously permitted to reach maturity is another and widely different question; in any instance, in such a variable season their development must be slow.

Those who delayed the pruning of their Roses till the present period, have reason to congratulate themselves upon such prudent procrastination. We cannot say with the poet, with reference to this matter at least: "'Tis madness to defer."

The great attractions of April, on whose confines I am writing, are the flowering trees. The flower-buds of the Almond are preparing to expand their pale-pink splendours o the sun, and the season of luxuriant bloom for the Plums and the Cherries, judging from their aspect, is not far away. Already we have the earliest of the Auriculas, perhaps the most fragrant, and not the least beautiful, of vernal flowers; when they begin to unfold their odorous treasures, we know from experience that summer with all her glories is near. One floral revelation, each more lovely than its predecessor, is followed by another, as wave flows into wave on a boundless sea. Such is the infinite variety of Nature, by which our spirits are constantly inspired, and thus rescued from weariness, yea, even from despair. What were this life of ours, with all its environing mysteries of sorrow and suffering, without its sunlight and its flowers? And yet, as Mrs. Hemans has so touchingly sung:—

> "Alas, for Love, if thou wert all,
> And nought beyond—O, Earth!"

The reign of the Primrose, one of the purest and gentlest daughters of Nature, has already begun. This peninsular parish is peculiarly a region of Primroses; here they appear to him who loves them to have found their happiest home; they clothe the green slopes that rise softly from the waters of the spacious Bay of Luce; and glorify the rocks that tower in stern majesty over the western Irish Sea. They have many floral companions there, all of them fascinating in their form or colour, their picturesque position, or romantic environment; but none so gracious, so fragrant, or refined. They are the children of adversity; they are borne amid atmospheric tribulation, equinoctial storms, and desolating rains; yet serene in their beautifully-sheltered recesses, they are the parents of hope—they speak to our natures of brighter days to come.

In our gardens, unless perhaps in shady green places, where they have the companionship of the Daisy of Burns and Montgomery, and the Celandine of Wordsworth (and such retired situations I have provided for them here), they have a somewhat alien aspect, as if they were longing for their native places, the shadowy glens, where they harmonise so gracefully with the sweetly-scented Scilla nutans; or green sequestered nooks amid the heather, above the sunny shore.

Of Primroses more suitable for garden cultivation my favourites are the Double Crimson, with its charming velvety hue; Primula denticulata, whose colour is bright lilac, and whose habit is unique; P. nivalis, with its snow-white flowers—a veritable gem; and, above all, the nobly-endowed Primula rosea from the Himalayas; of which the grandest form, P. grandiflora, first flowered at Aberdeen.

I cannot close this fragmentary article without some recognition, however inadequate, of the kindness of Mr. Melville, head gardener to the Duke of Sutherland at Dunrobin Castle, in sending me recently some very precious flowering bulbs of the magnificent Snowdrop, Galanthus nivalis Melvillei, which was raised by himself, and appropriately bears his name. He sent this variety, contemporaneously, to Mr. Arnott of Carsethorn, who may be regarded as an authority on alpine and herbaceous flowers. It is the largest and loveliest Snowdrop I have yet acquired—a most valuable addition to my floral possessions. *David R. Williamson.*

NURSERY NOTES.

MESSRS. J. VEITCH & SONS, LIMITED, THE ROYAL EXOTIC NURSERY, CHELSEA.

THE visitor to this establishment at the present time will find much to interest him in the numerous glasshouses. Does he wish to refresh his memory with a sight of New Holland and Cape plants, there are houses and pits filled with Boronias, Tetrathecas, Pimeleas, Acacias, Callistemons, and others of those generas, and he will be loth to leave the sweet-scented bushes of Boronia megastigma. A novelty was noted in foreign-grown standards of Callistemon rigidus, with heads 1½ foot in diameter, well furnished with buds of their brush-like flowers. The "Flower House" is filled with all sorts of popular greenhouse subjects, grown as only specialists can grow such plants, to match which the private cultivator may well despair. Here was that pretty-flowering semi-hardy perennial herb Dimorphotheca Eckloni, a Composite, with flowers milk-white within and pale purple without. Its flower-stalks reach a height of 2½ feet, and the flowers are sufficiently numerous as to make it decorative. Deutzias, Azaleas, Lilacs, Cytisus, Calceolaria herbacea, Rhododendron hybrids, Dutch bulbs, and Narcissus, formed the major part of a very pretty display.

The warm-house Rhododendrons are evidently the Londoner's plant *par excellence,* no phase of London climate being inimical to them, as the vigour of their growth at the present date shows. Later on, the trusses of blooms will be very fine and numerous. We only saw a few in bloom the other day, and among them the handsome Balsaminæflorum album. Other plants remarked as coming on in quantity are the Phyllocactus, the floral display from which will exceed that of any previous year.

The Hippeastrum-house was gay with numerous flowering bulbs, and the following were noted as being more than ordinarily distinct. Tarascon, a bloom of a very fine shade of deep crimson, smooth and regular in shape; Troilus a crimson self of another tint, and with a velvety appearance; Bryges is similar, and with a glistening surface; Cupid is a scarlet, with white stripes, and a greenish stain at the bottom of the flower; Maer is a pretty bloom, white, with faint stripes of a crimson tint; Dumas is a scarlet bloom, having white bands: a bright and distinct variety; Lago is a deep crimson self, of regular shape, and much substance in the flower; Python, a rich velvety-crimson, of a fine shape, is one of the best; in the same way is Quintus, but with a light crimson band running down the middle of each segment; Euryllis is a white-ground flower, with broad and narrow stripes of a crimson tint; Enita is similar, but it has fewer stripes.

The aim of the hybridiser now, is to get away from self-coloured flowers, and to raise such as possess at the least a clear ground-colour with markings of some other well-contrasted colour; and another quest is that of a yellow-flowered variety. The nearest step to this consummation at present existing is a flower of salmon-red, with the faintest tinge of the desired colour. The display of these bulbs will endure for about a space of three weeks, the actual length of time being dependent on the weather.

THE ORCHID HOUSES

disclosed many fine hybrids and other plants. Of the former we may mention a delicately tinted Chysis Sedeni, obtained from C. Limminghi and C. bractescens; Dendrobium Alcippe out of D. lituiflorum Freemani and D. Wardianum, partaking more after the former; D. Venus, obtained by crossing D. Falconeri and D. nobile, a very pleasing flower, with considerable resemblance to the latter species; D. Euterpe, out of D. Wardianum and D. nobile, remarkable for the pale tints of the flower; and D. albo sanguineum, with fawn-tinted sepals and petals, and purple-blotched throat. The creamy-white and yellow Bifrenaria Harrisoni candida was carrying a goodly number of blossoms.

The show of flowers in the Odontoglossum-house, judging from the mass of advancing flower-spikes, will be a good one, especially the species Alexandræ, Pescatorei, and cirrosum. In the large house were numbers of blossoms of Cattleya Schroderæ in much variety of colour as regarded their labellums. A plant of Cattleya Lawre-Mossiæ, a new cross between C. Lawrenceana and C. Mossiæ was remarked, and one of C. Schroderæ eximia, which has an attractively frilled lip, and a cincture of crimson in the tube. A plant of the Sedenian hybrid Lælio-Cattleya Pallas was in bloom in this house; and in an adjoining house the rarely seen Cypripedium Lindleyanum, as also C. Chamberlainianum. Of plants of Aërides japonicum there will be a nice display in about a fortnight.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Cabbages.—Let the main crop be forthwith earthed up, if it be not already done, and set out more plants from the seed beds. Cabbage Early Ellam's will now be forming hearts, and where they have been planted thickly, every alternate plant may be pulled up for present consumption. The larger varieties will follow these, but I fear many of Enfield Market will bolt this year. Several sowings of Cabbage-seed should be made from March to July, and planted out in moderate numbers, so that no scarcity of this indispensable vegetable can occur. The early beds, which most gardeners preserve for supplying sprouts, such as Early Evesham, Ellam's, and several of the smaller quickly hearting varieties, are sure to prove of great value. Keep the hoe in constant use amongst the various plots. Plants raised in heat should, after duly hardening them off, be planted out in showery weather, but if there is no immediate reason for planting them, it will be better to keep them growing under glass, i.e., in frames, till the weather gets more settled.

Peas.—Let all Peas requiring support be staked in turn, first drawing a little soil up to the plants, and for a time bits of Spruce, Fir, and Laurel may be stuck along the rows to give shelter against wind and frost. Even the dwarf William Hurst, Chelsea Gem, and others will benefit from this sort of shelter. As soon as the latest sowing of Peas shows above ground, some of the more tender large-growing Marrow-fats may be sown in drills drawn 2 inches deep, this depth being preferable at this early date.

Spinach.—Seed of Spinach should be sown at weekly intervals of time if the demand is a constant one, employing the variety Victoria, which is superior to the old round-seeded Flanders Spinach, in having larger and more succulent leaves, and in not running to seed quickly. It is quite as hardy as the winter Prickly Spinach. Sow thinly, and when large enough to pull up by hand thin the plants to 6 inches apart. Spinach likes a good-holding, rich soil, and if partially shaded no harm occurs in the summer months; for example, two rows may be sown between two rows of Peas, when these are sown. Should the soil be dry when the drills are drawn, apply liquid manure, and sow the seeds soon afterwards. Seeds of the so-called Spinach Beet may be sown, the leaves of which may serve to fill a gap in the supply. The seeds of this plant should be sown in drills drawn 1½ foot apart, and 8 inches from one patch of seed to another, and be singled when large enough to handle. One sowing made in this month will suffice for the season.

Mustard and Cress.—Seeds of Mustard and Cress may now be sown at short, regular intervals of time, on a sheltered and warm border, as also fortnightly the seeds of Radishes, and Golden or Normandy Cress. The beds of Radishes should for a time be protected against birds, or much of the seed will be carried off. In the event of very cold or very dry weather, mats or clean straw should be laid over the seed-beds till germination has taken place. The varieties of Radishes are legion, therefore I do not specify any variety. If the accommodation under glass is limited, and the supply of Lettuces for salad is likely to fall short of the demand, a sowing may be made in shallow boxes, choosing for the purpose a quick-growing variety. The entire plants, if cut when large enough, will make nice dressed salads, and save the outside plants for some time longer. Let seeds of the larger Cos varieties be sown at bi-weekly intervals, in lines on firm, rich soil, in the open quarter, and thin the plants to 10 inches apart. Lines of cotton-thread may be stretched along the rows to keep off birds; also sprinkle with lime and soot to deter slugs.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Lawns.—Before mowing begins, a lawn should be thoroughly swept and rolled, but before this is done, the coarser weeds found in the turf should be spudded out, and the holes made in doing this filled up with fine loamy soil, and made quite firm with a rammer after sprinkling the surface with lawn grass-seed. Plantains are nasty weeds that should always be removed from the turf root and stock, for if any portion of the roots be left in the soil, the crowns will still further increase in size. On places where the grass is thin, fine grass-seeds should be sown after scratching the surface with a rake, and be covered slightly with fine soil, and finally made firm with the lawn-roller. The same methods apply in laying down new lawns with seeds. If a lawn mixture be purchased from a trustworthy source, the quantity of seed need not exceed 80 lb. per acre. Those who like to use Clover on the lawn should sow the seeds before the grasses, hacking them into the ground with a wooden rake. The best species are Trifolium repens and T. minus; the first-named may be sown at the rate of 6 lb., and the second 2 lb. per acre.

Hardy Ericas.—The plants of Erica herbacea carnea, having now passed out of flower, should be clipped-in hard. When planted to cover rock-work on a big scale the leading shoots may be left untouched, and these will in time form large cushions of bloom. E. mediterranea, and its varieties alba, carnea, glauca, and rubra, flower during the month of May, and need similar treatment after flowering. E. vagans blooms in the early autumn; and it forms a nice edging to beds of Ghent and mollis Azaleas, and when allowed to grow naturally it makes handsome bushes. The Ericas grow in any light loamy soil free from chalk or lime, but when planted in sandy peat the leaves and flowers come of a darker tint.

Gaillardias.—These handsome perennials succeed in hot places in the garden, where other plants would be liable to be withered up by the heat of the sun. The soil for them should be of a light nature, well enriched with manure, and deeply dug. Gaillardias are most effective when planted in groups of several together, planting them individually at 8 inches apart, spreading the shoots out, and pegging them down so as to cover the ground. The following have very fine flowers of various shades of yellow with crimson centres:—Comet, Her Majesty, James Kelway, Old Gold, Primrose Dame, Vivian Grey, Oliver Wendell Holmes, and William Kelway. The varieties W. B. Child, Lord Rosebery, and Sir Vindex, with beautifully-notched petals, are superb as cut flowers.

Gynerium argenteum (*Pampas-grass*).—Clumps that have become bare in the centre should be dug out, the exhausted soil removed to the depth of 3 feet, and be replaced with rich pasture-loam three-fourths, and manure one-fourth. The healthy portions of the clumps may again be planted at a suitable distance apart, so as to admit of considerable increase in size, as the plants should not require removal for half-a-dozen years. The plants are usually found in gardens in two sexes, but the inflorescence of the female is of a purer colour than that of the male, and lasts longer in perfection. When well-rooted, the Pampas-grass needs abundance of water in the summer season.

Annuals.—The young plants of Asters, Zinnias, Stocks, Helichrysums, Amaryllis, and other strong-growing annuals should be pricked-out in pits, the soil of the beds being raised near to the glass. Let each plant have as much space as will allow it to grow without being drawn or made weakly. The yellow Pyrethrum, the dwarf-growing Lobelias, and the annuals of small growth do well in boxes.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen.

Miltonia Roezli, &c., has the reputation of being a short-lived Orchid when cultivated under glass. Experience, however, has convinced me that it is as easy to maintain in a healthy condition as its more popular relative, M. vexillaria. A moist, warm, and shady position should be selected for M. Roezli. The plants require to be watered overhead frequently, and to be so placed that the air can circulate amongst them freely, but avoiding at the same time cold draughts. Place a layer of sphagnum-moss over an open lath stage, and stand the plants above this on inverted pots. The roots are apt to die when the peat and moss has decayed, and therefore this material must be replaced before it has reached this condition. Select small pots, and provide them with a large amount of drainage, working in amongst the roots of the plants a small quantity of peat and sphagnum-moss in equal proportions. The leaves must be sponged to prevent injury from thrips and red-spider, and to the same end an occasional fumigation of the house may be afforded. Miltonia Bleuana ×, the hybrid between M. Roezli and M. vexillaria, will thrive under similar conditions excepting that a lower temperature is necessary, such as that of the warmer end of the Cattleya-house.

Cattleya intermedia will require attention as soon as the flowers have been removed, for new roots will then have formed. This desirable Orchid needs the warmest and most shady part of the Cattleya-house, and a somewhat liberal supply of water during the resting period, on account of its thin pseudo-bulbs. The albino forms do best when grown in well-drained pans, suspended from the roof of the same house. A small white scale attacks these plants, and considerable care is necessary to remove it without damaging the dormant buds. A small, rather stiff-haired painter's brush, moistened with soap, is the best means to use.

Lælio-Cattleya elegans.—The various forms of this beautiful Orchid do not commence growth simultaneously, by reason of their diverse parentage, but from now onwards the plants will need to be looked over and potted or top-dressed as required. Position influences the growth of the plants to a very great extent, and if they cannot be induced to thrive they should be placed in various positions with a view to finding the best one. The conditions prevailing in the Cattleya-house suit these plants, but the distance of the stages from the roof should determine whether the plants need suspending or not. The Teak-wood baskets are suitable for them, but a difficulty arises when a larger one is required; the impossibility of removing the rods of the basket without injury resulting to the plant on the one hand, and the undesirability of burying the wood in a more commodious receptacle on the other being a great drawback. With the smaller specimens this difficulty is got over by using perforated pans, of which perhaps the best is Sander's Perfect Orchid Pan. When plants growing in pans need larger ones, it is a matter of ease to break them and place the pieces to which roots are adhering in the new ones, thus preserving the roots and adding drainage at the same time. The material used as a rooting medium should consist principally of peat, with but little sphagnum-moss. A soddened base is fatal to good health, and tends to produce that peculiar disease known amongst Orchid-cultivators as "black rot," a disease that probably attacks L.-C. elegans more often than any other Cattleya.

Dendrobiums will now claim attention in the matter of re-potting and top-dressing, amongst the first being the ubiquitous D. nobile, and the various hybrids obtained from it. Plants when they pass out of flower should be removed to the East Indian-house, or some similar structure, and allowed to have a rest for a fortnight before being disturbed. Dendrobiums of this section are well adapted for growing in baskets, preferably those of a cylindrical nature, which allow the water to escape readily, and have more wood to which the roots may cling. Use fibrous-peat and living moss, and as little as possible to each plant. I find that for large specimens, grown in cylindrical baskets, that the thick bracken roots taken out of the peat forms a good substitute for ordinary drainage, though a few pieces of crock should be introduced to prevent the above becoming soddened. A careful application, and a limited supply, of water is essential for some time after the plants have been disturbed.

Lælia anceps and its varieties now making numerous roots, should be at once overhauled, and specimens that have sufficient rooting-room be top-dressed only, but others should be carefully removed to larger receptacles. Teak-wood baskets best fulfil the requirements of large specimens, and when possible the plants should be so arranged that their subsequent growth will take an inward direction. Small plants may be grown in pans, which can be broken in pieces when a shift becomes necessary. Large pieces of crock should be placed in an upright position for drainage, covering these with a small quantity of peat and sphagnum-moss, the former predominating. Place the plants in the Mexican-house where little shade is used and a large quantity of air admitted. The syringe may be employed on bright days, and the plants kept well moistened in the ordinary way.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Disbudding Peach and Nectarine-trees.—Since milder weather set in, the trees on the south wall have made much progress, making disbudding a matter that must soon be afforded attention. In carrying out the operation of disbudding, a tree should be scrutinised three or four times at intervals of a week, and each time some buds should be removed, choosing for removal the forerights and those under or behind the shoots and branches, never taking many of them at one time. The branches and shoots of a Peach-tree usually radiate from about the centre of the tree; and this being so, the buds, which will in time develop into shoots, are the more suitably placed on the top-sides of the branches, not that a tree therefore bears more or better fruits, but the work of laying is simplified, and crowding of foliage is more readily obviated. Having disbudded the back, front, and lower parts, attention must be paid to these. The Peach will sometimes fruit on short spurs, which are formed by pinching foreright shoots back to two or four leaves, but, all things considered, it is better to ignore this fact and obtain fruit from the young wood only. One thing must be avoided, and that is, leaving so many shoots that they cannot be nailed or trained between existing branches without crowding the foliage and hindering the ripening of the shoots. Oftentimes one bud at the base of last year's growth and the terminal one are as many as ought to be retained, more especially when a tree has filled its allotted space. A young tree will require great care in disbudding, as upon the removal or non-removal of certain shoots, the shape and appearance of the tree will largely depend. Where Peach and Nectarine-trees were thoroughly syringed with some mild insecticide before the blossoms opened, greenfly will scarcely prove troublesome at this date. If, however, any should make their presence known by the leaves curling up, dust the foliage with tobacco-powder, and as soon as the bloom is set, syringe the trees with clean water in the morning, or wash them with Quassia-water. This is at once a simple and safe operation if the weather be not frosty. The nurserymen sell a Quassia extract, which if used according to the printed directions sent with each bottle is a very safe and effective remedy to use against aphides.

The Removal of Tree Coverings.—Where Peach and Apricot-trees have been protected with fixed coverings, a partial removal of these should now take place, and in the case of fish-netting, leaving but two or three thicknesses for seven or fourteen days longer. Movable or sliding screens may be put out of use excepting on cold nights.

PLANTS UNDER GLASS.

By C. R. FIELDER, Gardener to the DOWAGER LADY HOWARD DE WALDEN, St. James's House, Malvern.

Climbing Plants.—Many of these are now making new growth, and these young shoots require to be regulated with a view to furnishing the allotted space on the trellis, and to prevent crowding and entanglement. This applies more particularly to such plants as Lapagerias, Tacsonias, Hibbertias, Dipladenias, and Thunbergias. Where Dipladenias are grown in pots they should be given a position at the warm end of the stove or other house in which a high temperature is maintained, and if the pots can be plunged in mild bottom-heat, growth will be greatly encouraged. Train the young shoots singly near the glass until the flower-buds appear, when they should be taken down and tied to a balloon trellis in such a manner as to distribute the flowers equally over the trellis. The tying should be done before the flowers have opened, so that there will be time for the foliage to assume its natural position. Of the climbers which are raised annually from seed and grown in pots, the Ipomœas, Thunbergias alata, Maurandyas, and Tropæolums are among the most useful. Ipomœa rubro-cœrulea and I. Quamoclit are very beautiful subjects for the conservatory. They may be very readily raised and grown if afforded a warm temperature during the earlier stages. At the end of the spring they may be transferred to the conservatory. They require liberal treatment, and if potted on from time to time will grow and flower through the greater part of the summer.

Bouvardias.—Old plants which were potted-up as previously advised will now be ready to be placed in their flowering-pots. These pots should measure from 6 to 8 inches in diameter, according to the size of the plants. A night temperature of 55° will be sufficient.

Double-flowered Primulas.—Old plants may be divided, and the rooted pieces potted. Offsets may be placed in thumb-pots filled with light soil, the base being surrounded with sand. Place them under a hand-light in an intermediate temperature, or at the cool end of the stove. When well rooted, they should be removed to a cooler house, and be potted into 5-inch pots.

Miscellaneous.—Cuttings of Euphorbia jacquiniæflora and Centropogon Lucyanus should be taken from the old plants with a heel when about 3 inches in length, and inserted in pots filled with sandy peat, and placed in the propagating-frame. Cuttings of the following plants may also be put in now: Manettia bicolor, Eranthemum pulchellum, Impatiens, Ruellias, Justicias, Salvias, Bouvardias, Coleus, &c. Annuals for conservatory decoration which have been pricked out into boxes should be put into thumb-pots as soon as they are sufficiently strong. Cuttings of zonal Pelargoniums for autumn and winter flowering should be potted-up as soon as they have rooted, and when again established the points may be pinched out.

VARIORUM.

THE MARQUIS OF BUTE'S WINES are now vended in the open market, and can be obtained by all who are interested in the noble marquis's vineyard experiment. Before me is an advertisement of Welsh wines "Canary Brand," guaranteed by the Marquis of Bute to be the produce of his vineyards, and to be of the vintage named on the label. The prices vary from 38*s*. per dozen for 1892 vintage to 44*s*. for 1887, and the wines are variously described as "golden, medium sweet," "full golden, rather sweet," "dark golden, medium sweet," and "luscious golden wine." But, alas! on perusing the advertisement in question further, the wine cup is partly dashed from my lips—I see that all the vintages but 1892 are sold out. I will, however, at once sample that, and record the result. *Midland Counties Herald.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	April 18	Royal Horticultural Society's Committees. National Auricula and Primula Society, Exhibition at the Drill Hall, James Street, Westminster. National Rose Society's Committee Meeting.
WEDNESDAY,	April 19	York Florists' Exhibition of Auriculas, Hyacinths, &c.
THURSDAY,	April 20	Linnean Society, Meeting.
SATURDAY,	April 22	Royal Botanic Society, Meeting.

SALES.

WEDNESDAY,	April 19	Greenhouse Plants, Roses, Herbaceous Plants, Begonias, Gladioli, &c., at Protheroe & Morris Rooms.
FRIDAY,	April 21	Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period April 2 to April 8, 1899. Height above sea-level 24 feet.

Remarks.—During the week there have been south and north-westerly gales, with some showers. On the 8th inst. there were storms of rain, snow, hail, and sleet.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—48 7°.

Actual Temperatures :—

London.—*April* 12 (12 P.M.): Max. 54°; Min. 36°.

Provinces.—*April* 12 (6 P.M.): Max. 48°, Lincoln; Min. 45°, Holyhead.

Buds and Stipules.

Now is the time to study the construction and unfolding of the buds. A more fascinating task when once the interest is excited can hardly be imagined. To young gardeners in particular the study of buds, their position, nature, and mode of growth, is of very great importance. If they are not concerned or interested in the beautiful transitions between and the perfect leaves, such as pre- elves so markedly in the Horse-Chestnut or the Maple, if they are apathetic in all that concerns the marvellous adaptations and provisions to shelter the young shoot and protect it from living enemies or adverse conditions, if they care for none of these things, then, at least, the pruning of a Gooseberry-bush is a matter of importance to them, and the treatment of fruit-trees and Roses demands their attention.

Sir John Lubbock has recently added to his substantial contributions on similar subjects a little volume on *Buds and Stipules* (Kegan Paul, Trench, Trübner & Co.), with numerous informing illustrations, which we cordially commend to the notice of our readers, amateur or professional. The lover of facts will be satisfied with the array placed before him, whilst the theorists who know how to use the facts, and the men who know how to turn them to the best practical advantage, will alike be pleased with a volume which not only indicates what there is to be seen, but offers lucid explanations of the phenomena. It is a popular book in the best sense of the term, technical, but lucid and attractive.

We cannot here do more than allude to the copious details that Sir John Lubbock has accumulated. Others have done that before him, but their work has been found dry and unsatisfying, because the structural conformation of itself does not interest everyone. Show that the conformation has a history and a significance; link the structure to the work going on in the plant; show the use and purpose of these elaborate arrangements, and eager listeners and attentive students are secured. In these pages, therefore, we have detailed descriptions of things as they are; but, more than that, we have the "why" and "wherefore" put before us in such a way as to ensure our assent.

The young leaves require protection against too great cold, heat, drought, or moisture, too vivid light, and the attacks of animals and plants. This protection is afforded in very varied ways by the bud-scales and stipules.

There is one point on which the author has perhaps not laid so much stress as the case demands, and that is, the occasional presence of numerous buds in the axils of the leaf, and their disposition. In such cases, if one bud be killed, another takes its place—*uno avulso non deficit alter.* Forsythia in full bloom at this time affords a good illustration of this abundant production of buds, as does also the Walnut. The paper of MM. Bourgeois and Damaskinos in the *Bulletin of the Société Botanique de France*, v. (1858), is important from this point of view.

Granted that the bud-scales and stipules have the office assigned to them, it is sometimes difficult to understand why some species are thus protected, and others not; thus, while some Passion-flowers have large stipules, as described by the author at p. 123 of his book, many others have the stipules reduced to mere threads, probably of no present use, though possibly survivals from a former condition when they were serviceable.

"The presence or absence of stipules," says the author, "is not determined by any question of general symmetry, but rather by practical considerations connected with the wants and requirements of the plants. In some cases they are merely the persistent rudiments or organs which performed a useful purpose to the ancestors of the existing species in bygone ages, and under different circumstances."

"If I shall," concludes the author, "have induced any of my readers to look at them for themselves in the coming spring, they will, I am sure, be amply rewarded. They will often be reminded of Tennyson's profound remark about Nature:

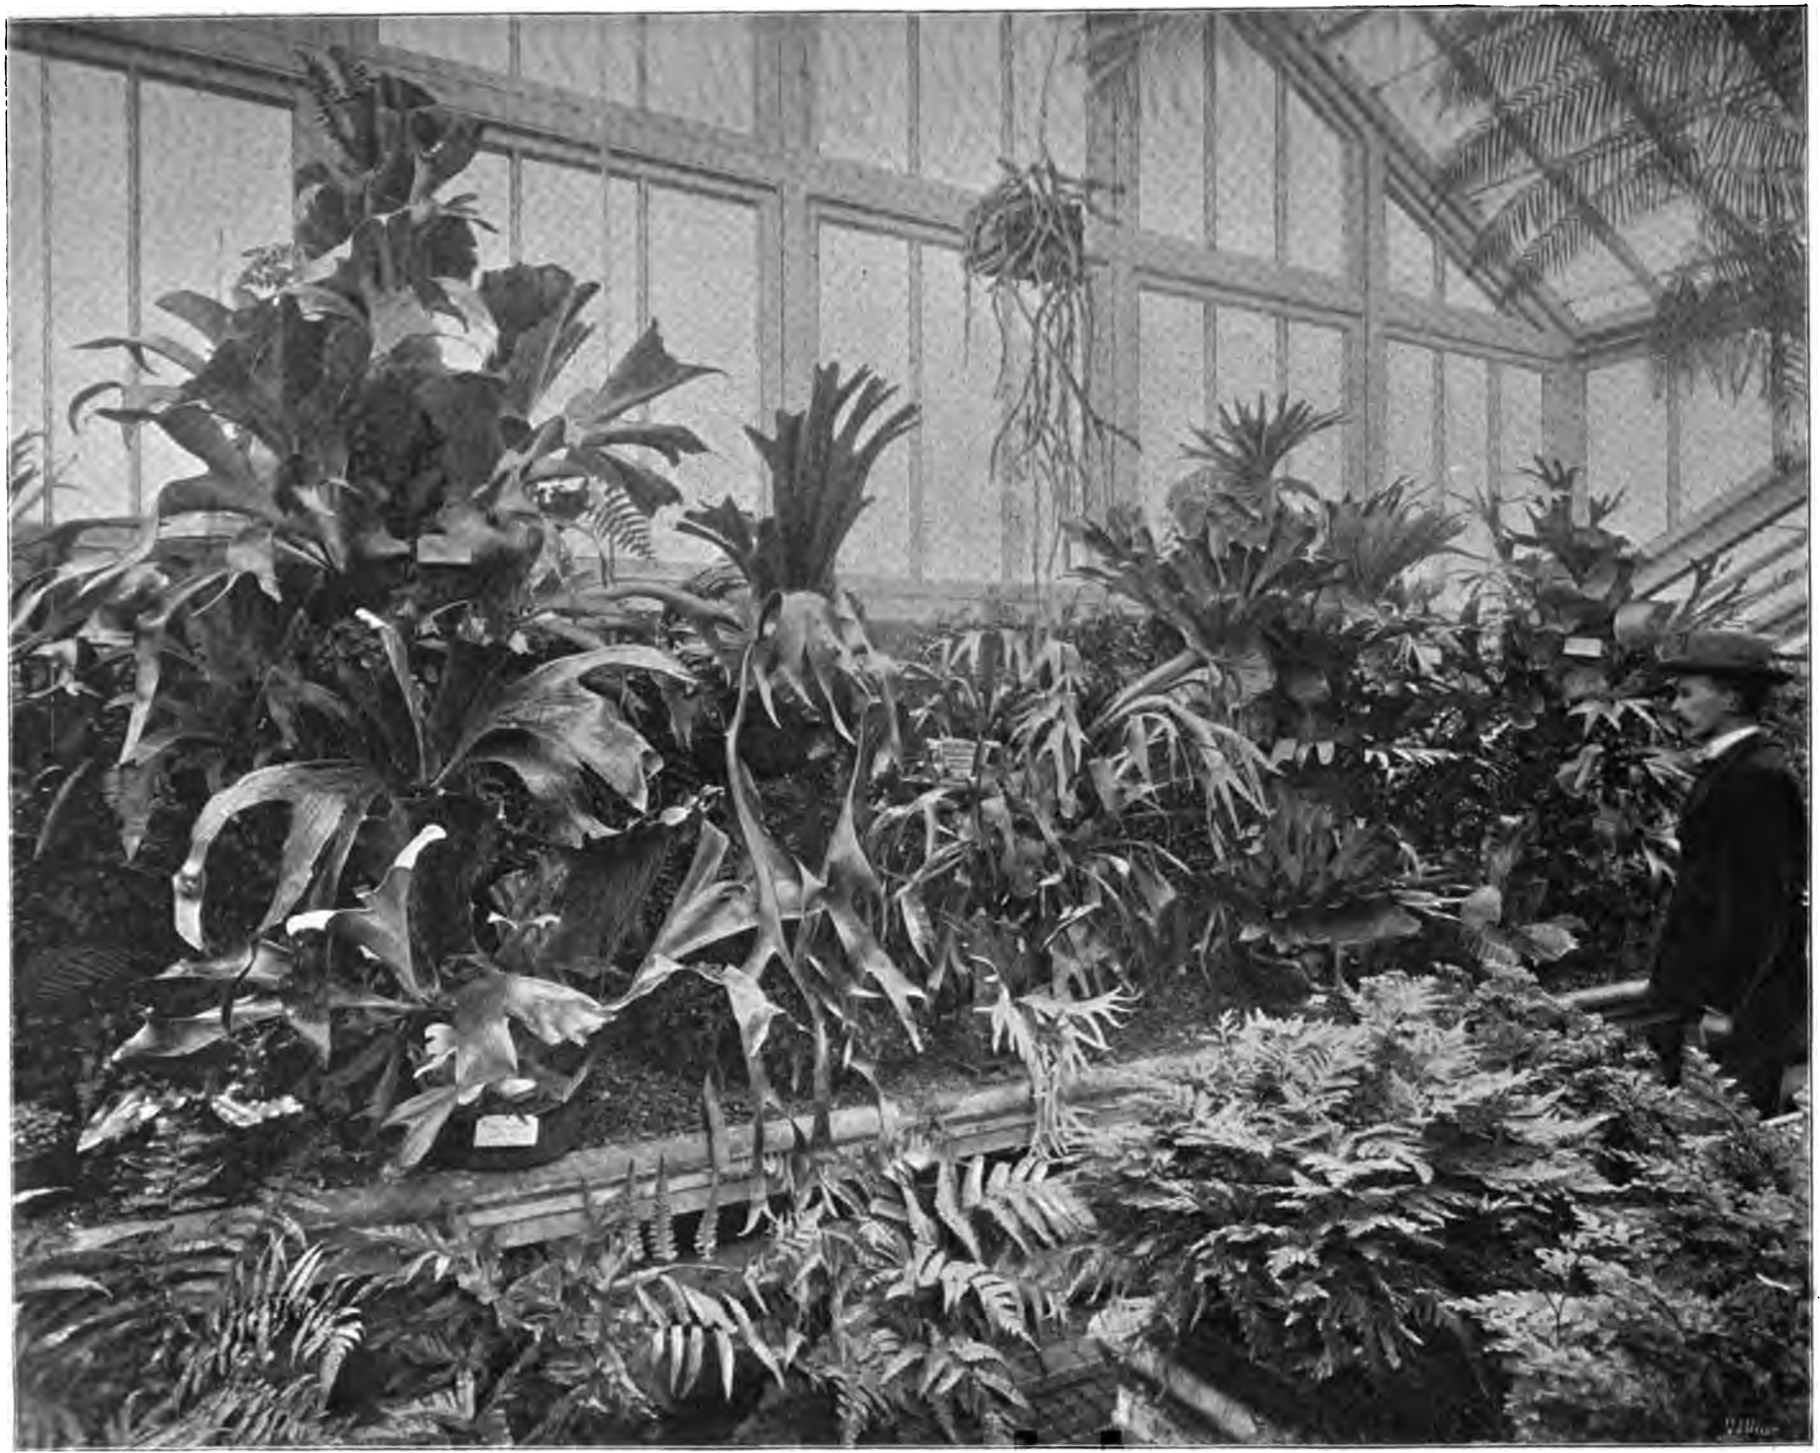
> 'So careful of the type she seems,
> So careless of the single life;"

and will be more and more struck with wonder and admiration at the variety and beauty of the provisions by which Nature preserves these tender and precious buds from the severity of winter, and prepares with loving care and rich profusion for the bright promise of spring, and the glorious pageant of autumn."

Platyceriums at Kew (Supplementary Illustration).—The annexed illustration represents the collection of Stag's-horn Ferns in the tropical Fern-house at Kew, where the conditions, since the house was altered, appear to be exceptionally favourable to the growth of these, and, indeed, most other tropical Ferns. The Platyceriums are growing on imitation tree-trunks, made of stout logs, to which large strips of cork-bark are fastened in such a way as to present the appearance of a gnarled trunk, and at the same time to afford pockets which are stuffed with sphagnum-moss and peat. The plants are held in position by means of copper-wire until they become established. The whole mass is kept constantly moist, and that the treatment agrees with the Platyceriums is abundantly evident. The large mass on the left in the picture is P. Stemmaria (æthiopicum), which has fertile fronds over 2 feet long. Next to it is a fine example of P. biforme with an enormous mass of brown barren fronds like an elephant's head; a newly-formed one, over 3 feet long, deeply lobed, and standing erect, as in P. grande, whilst springing from its base, and measuring 6 feet in length, are the fertile elk-horn-like fronds. This species is exceptional in that it produces its sori on a separate short, thick spoon-shaped basal lobe, instead of on the under side of the upper part of the prolonged fronds. This, which is probably the largest living example of this species ever seen alive in Europe, was sent to Kew two years ago by Mr. Ridley, Director of the Gardens and Forest Department, Singapore. Next to it stands a mass of P. alcicorne, some of the fronds of which are 2 feet long; then an equally fine "trophy" of P. grande, perhaps the handsomest of all the species, with its large, bold, deeply-lobed, bright green, barren fronds, 2 feet long, and over 3 feet wide, and its long, drooping-lobed fertile fronds. There is also a good example of P. angolense, of which a figure was published in the *Gardeners' Chronicle* last year, and one of the rare P. Wallichi; several varieties of P. alcicorne are also represented by large specimens. The Kew collection contains all the Platyceriums that are known to be in cultivation. There are several distinct species not yet introduced, two of them natives of Madagascar, viz., P. Ellisii and P. madagascariense, which, judging by dried specimens, are worth introducing. Possibly French collectors will forward them before long. The plants are easily cultivated, provided the essential conditions of heat, a sweet, open compost, and plenty of moisture are provided. They multiply rapidly by means of stoloniferous offsets and root-buds; they are also easily raised from spores. I lately saw a fine batch of young plants of the new P. angolense in Messrs. Sander's Nursery at St. Albans. *W. W.*

The Royal Horticultural Society's next meeting will be held on Tuesday, April 18, in the Drill Hall, James Street, Westminster, and the National Auricula and Primula Society will hold its annual show at the same time and place. There will also be an exhibition of Daffodils. At 3 o'clock a lecture will be given on "Asparagus, Forced and Outdoors," by Mr. Geo. Norman.

Linnean Society.—At a meeting of this Society, to be held on Thursday, April 20, 1899,



GROUP OF PLATYCERIUMS IN THE FERN-HOUSE, ROYAL GARDENS, KEW.

at 8 P.M., the following papers will be read :—I. "The Botany of the Ceylon Patanas," by Mr. H. W. H. PEARSON, B.A. ; II. "Imitation as a source of Anomalies," by Prof. R. J. ANDERSON, F.L.S. ; III. "List of British and Irish Spiders," by Rev. O. PICKARD, Cambridge, F.R.S.

NATIONAL ROSE SOCIETY. — The Hon. Secretaries desire us to inform our readers that a meeting of the Rose-soil Analysis Committee will be held at the Rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday, the 18th inst., at 2 P.M., to consider the best steps to take in regard to Mr. A. HILL GRAY'S suggestion that certain Rose-soils be analysed.

THE CYCLES' REST AT KEW.—In the House of Commons, on Monday last, Major BOWLES, M.P. (Enfield), drew attention to the want of accommodation for bicycles used by visitors at Kew Gardens ; and Mr. LOUGH (Islington), is reported by the *Times* to have advocated the formation of cinder-paths for cyclists in all the London parks, including Kew Gardens. Quite so ! let us have exhibitions of the "science" in front of the succulent-house, announced in the *Sporting Times*, and let the reports of the "events," in which female as well as male performers take part, be published in that organ of sport and in the *Kew Bulletin*. It is true it would be disgustingly inappropriate or very amusing, according to the diverse tastes of individuals, and Kew has to consider the desires of the public, including Mr. LOUGH, M.P.

THE LAW OF PRIORITY.—Count DE KERCHOVE has an amusing letter on this subject in the current number of the *Revue Horticole*. He records a supposed conversation in old French in which the plants named are called by their ancient names, which he truly says would be almost incomprehensible, although the law of priority would be respected. It is as if we were to write that the gardener had plucked some "hnutu" near the "haeguthorn," and gathered some "merici" under the "mapuldur." By right of priority, the "Hazelnut," the "Hawthorn," the "Parsley," and the "Apple-tree," should, in the opinion of some folk, lose these well-known designations, and resume those we have above cited from the Epinal Glossary (8th century). But then there would be no finality. Professor STRAWBRICK may find somewhere amid the ruins of the Tower of Babel evidence of the use in pre-Babel days of names other than those in the Epinal Glossary. What then? Obviously some botanists will never be content till they have discovered or manufactured an "Index Edenensis," compiled by one ADAM, Protokeepōros.

THE SPRING FLOWERS on the grass and in beds at the Regent's Park will be very beautiful in the course of a few days. At present, varieties of the Grape-Hyacinth, and of Scillas, in full flower, nestling at the foot, and partially encircling small shrubberies, have a most attractive appearance.

CHALLENGE CUP FOR DUMFRIES FLOWER SHOW.—The Dumfries Town Council have resolved to vote a sum not exceeding £15 for the purchase of a Challenge Cup to be competed for at the Dumfries and Galloway Horticultural Society's show. The Dumfries and Galloway Society, as resuscitated, will hold its show in the Drill Hall, Dumfries, on Wednesday, September 6.

STOCK-TAKING : MARCH.—The terrible weather experienced in many parts of the world during the past two months, added to the serious commencement of speculation in certain imports, must take credit for the heavy diminution in the value of imports during the month of March as compared with the same period in 1898 ; thus, last month's total is given at £41,492,388, as against £43,412,829 —a decrease of £1,929,441. The heaviest decrease is to be found in raw materials for textiles (£1,330,527) ; this is followed by £1,249,487 (articles of food and drink, duty free) ; £205,302 in the section of "animals, living, for food," and other smaller amounts ; the "increases" being in metals (£737,542) ; miscellaneous articles (£107,291) ; also manufactured articles, raw materials for sundry industries, &c., with a total of £94,249. Our usual extract from the "summary" table is as follows :—

IMPORTS.	1898.	1899.	Difference.
	£	£	£
Total value ...	43,412,829	41,492,388	—1,920,441
(A.) Articles of food and drink — duty free	14,894,777	13,645,290	—1,249,487
(B.) Articles of food & drink—dutiable	2,242,124	2,206,597	—35,527
Raw materials for textile manufactures	7,737,056	6,406,529	—1,330,527
Raw materials for sundry industries and manufactures	3,635,334	3,648,872	+13,538
(A.) Miscellaneous articles	1,397,628	1,504,919	+107,291
(B.) Parcel Post ...	141,117	112,094	—29,023

We may note that Hops figure for £58,863, against £63,063 in March, 1898 ; seeds (including Clover and grass, equal £89,424 last month, £127,329 same month last year), were entered to the value of £582,119, against £601,425 in the same period 1898. The value of timber and wood figure at £637,190, against £641,755 for March in 1898. We pass on now to the enumeration of fruit, roots, and vegetables, imported in the last month as follows :—

IMPORTS.	1898.	1899.	Difference.
Fruits, raw :—			
Apples ... ... bush.	160,779	231,931	+71,152
Grapes ... ... „	1,649	2,880	+1,231
Lemons ... ... „	123,904	107,311	—16,593
Oranges ... ... „	1,022,846	1,357,443	+334,597
Pears ... ... „	3,153	3,030	—123
Plums ... ... „	90	58	—32
Unenumerated... „	68,701	76,385	+7,684
Onions ... ... „	272,059	395,686	+123,627
Potatos ... ... cwt.	635,872	67,894	—567,978
Vegetables, raw, unenumerated ... ... value	£109,289	£129,200	+£19,911

We may, too, refer to the loss of the steamship *Labrador* and its cargo of first-class Canadian Apples— which latter, after floating about the coast in barrels, fell to the lot of island youth and cattle, with neither of whom did the sodden fruit agree. The minus figures in the above table are well worth consideration by the cautious grower ; the plus quantities have long since been thoroughly appreciated. The total of the three months' report is £118,242,584, against £119,099,209—a decrease of £856,625. The final section of the paragraph is devoted to our

EXPORTS.

Those have gone up somewhat—the total for last month being placed at £22,324,401, as against £20,833,865 for the same month in 1898—or an increase of £1,490,536. The greatest increase is in ships, new, not registered as British (not recorded prior to 1899), of £1,474,067. The items of decrease foot up at £708,663 ; those of increase (apart from ships, including £185,860 for machinery and millwork), give £725,132. It may be noted that orders for railway works, including locomotives, have found their way from this country into Belgium and the United States, and this is mentioned as derogatory to our workmen ; we believe the fact is, that our great factories are now and have long been overloaded with orders. The figures for the past three months are £62,054,941, against £57,707,118 for the same period last year—a gain of £4,346,923.

THE ROYAL SOCIETY.—The list of candidates for election this year contains no fewer than seventy-six names. Of these only fifteen can be elected. The Council will recommend to the Fellows that certain candidates be elected, and the Fellows will adopt or reject the nomination of the Council as they think fit, substituting some other name or names for those that they eliminate. How much simpler and less costly is this system than the troublesome and wasteful method of election adopted by our gardening charities. Canvassing is, of course, wholly prohibited. Among the candidates this year, we notice the following botanists :—Mr. J. S. Gamble, the author of the *Manual on Indian Timbers*, and the *Monograph of Bambuseæ* ; Mr. W. P. Hiern, the author of numerous monographs, and of the *Catalogue of Welwitsch's African Plants* ; Clement Reid, of the Geological Survey ; Dr. Schlich, Professor of Forestry at Cooper's Hill ; and Professor Perceval Wright.

"BOTANICAL MAGAZINE."—In the April number the editor gives an account of the appearance in his garden of a variety of Impatiens called—

Impatiens Roylei var. pallidiflora.—The plant differs from the common type in its taller stature, longer leaves and flowers, the latter being of a pale lilac colour spotted with rose-coloured spots. The plant is supposed to be a native of the Sikkim Himalaya ; t. 7647.

Cereus Paxtonianus.—This columnar Cereus is now seen to be specifically the same as C. Cavendishi with which it has been united by SCHUMANN. The native country is unknown. The flowers are nearly 4 inches across, greenish flushed with rose on the outer, white on the inner surface of the petals, Kew ; t. 7648.

Silene Fortunei, Visiani.—A common Chinese plant originally introduced by FORTUNE. It is a perennial with oblong linear leaves and terminal cymose clusters of rose-coloured flowers, with deeply laciniate petals, Kew ; t. 7649.

Yucca elata, Engelmann.—A native of Arizona, recently introduced to Kew. It has a branching stem about a yard high, with broad-based leaves suddenly contracting into linear blades, filiferous at the margins. The inflorescence is a many-flowered panicle, flowers broadly campanulate, about 4 ins. across, greenish white ; t. 7650.

Incarvillea variabilis, Batalin. — A beautiful perennial with deeply pinnately divided foliage, and racemes of rosy-lilac flowers. The corolla is over an inch long, with a narrow yellow tube expanding into an oblique, 5-lobed, spreading limb. It is a native of Western China ; t. 7651.

THE GARDENERS' COMPANY.—A meeting of the court was held on Thursday, April 6. Mr. W. A. BILNEY was admitted to the freedom and livery. A scheme for admitting members of the craft and working gardeners to the Company's freedom, and for granting trade certificates of competency on the result of an examination under the auspices of the Company, was laid before the court by Mr. C. Welch. After considerable discussion, the scheme was referred to a committee, consisting of the Master (Sir William Farmer), Mr. N. N. Sherwood, Mr. C. Welch, and the Clerk (Mr. R. Gofton-Salmond). It was also decided to proceed with a new edition of the short account of the company which was issued in 1890. A proposal to prepare a history of the company and of gardening in the City of London was also favourably received, and reserved for fuller consideration. Among those present were Colonel T. Davies Sewell, Mr. J. Curtis, Mr. C. E. Osman, Mr. A. Barker, Mr. Beaumont Shepheard, Mr. G. Corble, Mr. H. Wood, Mr. R. L. Devonshire, Mr. H. Haines, and Mr. R. I. Tasker. Sir William Farmer, at the close of the business, entertained the members of the court at Dinner at the City Carlton Club, St. Swithin's Lane, Mr. W. A. Bilney, the newly-elected liveryman, being the guest of the evening. *City Press.*

AMSTERDAM.—A large flower-show will be held next week in this city, under the auspices of the "Natura Artis Magistra." It will be visited on the first day, Sunday, April 16, by H. M. the Queen of the Netherlands, and will remain open for three days. On Monday afternoon an explanatory lecture will be given by Mr. J. K. Budde.

HORTICULTURE APACE WITH CIVILISATION.—On the 8th inst. we received a letter from an established florist and seedsman in Bulawayo, Rhodesia, respecting a horticultural appliance he had seen recently mentioned in these columns. It is gratifying to find horticulture thus abreast with the other civilising agencies.

FROST IN CEYLON.—Mr. Nock writes to the *Ceylon Observer* a note on the frost which occurred at Nuwara Eliya on March 7, 8, 9 last. At an elevation of between 5000 and 5700 feet, Mr. Nock made a list of about fifty species of plants that had been more or less injured by frost, including native species, as well as those like the Tree Tomato, Richardia africana, and Eucalyptus robusta, which have been introduced. In seventeen years' experience, Mr. Nock has never seen such an amount of injury.

GHENT CERTIFICATES.—At the usual monthly meeting of the Chambre Syndicale, presided over by M. L. Draps, the following Awards were made:—

CERTIFICATES OF MERIT.

For Cattleya Mendeli, Souvenir de Mdme. Frederic Coryn, shown by M. E. Coryn.

Cliveia President Bruneel, shown by M. De Vriessere-Remens.

Cocos Weddelliana gracillima and Anthurium Rothschildianum by M. A. De Smet.

Cliveia Mdme. De Vriessere-Remens, shown by M. De Vriessere-Remens.

For Cliveia Mdme. Jean Verbauen, by acclamation, Mr. J. Verbauen.

For Nicotiana affinis, shown by M. A. Dallière.

For Anthurium Scherzerianum "Distinction," shown by Messrs. Vervaene-Vervaet et Cie.

Azalea Marie Antoinette, from the "St. Fiacre" establishment.

Cultural Certificates were awarded to—

Oncidium lamelligerum, shown by M. L. De Smet-Duvivier.

Vaccinium Sprengeri, by Mr. E. De Cock.

Epidendrum Wallisii, by M. L. De Smet-Duvivier.

A CULTURAL COMMENDATION.—Mr. B. L. Hammett, of Trewhiddle Gardens, Cornwall, obliges us with photographs of his plants of D. Wardianum and D. crassinode. The cultivation is admirable, as our readers will agree when it is stated that a pseudo-bulb of the first-named variety measured 3½ feet in length, and produced thirty blooms. We have figured both plants on various occasions.

JOBBING GARDENERS.—It will be seen from an article in another column that the Inland Revenue authorities "do not require a licence to be taken out for a jobbing gardener employed at several places and working one or two days a week at each." Where a man supplied by a nurseryman, occupies his whole time, every day in the week, in attending to one particular garden, then he must be licensed. The licence must be taken out by the nurseryman, not by the hirer of the gardener, and the nurseryman must arrange with his customer as to the payment of the impost by increasing the cost of hire, or by curtailing the number of days per week on which the man has to work, and so escaping the licence altogether.

EMIGRATION TO THE COLONIES.—We learn from the latest-issued circular of the Emigrants' Information Office, that in Victoria there are excellent openings, as a rule, for farmers, dairy-farmers, and fruit-growers, if they have a little capital, and some experience of the country. There has been a general rainfall, and a very good harvest, and the dairying industry has improved. In New South Wales, at Uralla and Grafton in the far north, there is a fair demand for farm labourers and carpenters, and a good one for servants. Really skilled dairymen and thoroughly capable farm labourers would probably have little difficulty in obtaining employment in many parts of the Colony. Domestic servants continue to be in steady demand throughout the Colony, and the last annual report of the Government Labour Bureau draws attention to the difficulty of getting them. There are more than enough of ladies' helps, ladies' companions, and governesses. In South Australia there is no improvement in the demand for labour, except that there has been a demand for married couples without families for farms and stations; about 2000 persons have registered their names at the new Government Labour Bureau. In Queensland there is a general demand throughout the colony for ploughmen and other farm labourers, and for female domestic servants. Free passages are again being given to labourers and female domestic servants; and some assistance towards their passages is also now being given to farmers, market gardeners, dairymen, and fruit-growers, and their families. Application must be made to the Agent-general, 1, Victoria Street, London, S.W. In Western Australia there is a good demand for farm labourers in the south-west; and the mining industry continues to expand. The assisted passages to the Colony have been discontinued.

DROPMORE, TAPLOW.—An account of this famous home of Conifers, historical and otherwise, appears in this month's *National Review*, from the facile pen of the Hon. Mrs. Boyle. Many of our readers will recall with pleasure a series of articles by this lady, writing under the initials "E. V. B.," which appeared in the *Gardeners' Chronicle* a few years ago.

"ROSES IN POTS."—The eighth edition of this useful little book has been issued by Simpkin Marshall & Co., Paternoster Row. Nothing need be said in further commendation of so well tried a book, unless it be to say that the list of Roses is kept "up to date."

BROWNEA GRANDICEPS (*Bot. Mag.*, 4859).—A small plant of this handsome evergreen stove tree (Leguminosæ), bearing a truss of blooms, may now be seen in the Water-Lily-house, Royal Botanic Society's Gardens, Regent's Park.

BOOKS.—In the current number of the *Tijdschrift Voor Tuinbouw*, is a descriptive list of works on landscape gardening and other branches of gardening, by Mr. Leonard A. Springer. The list is evidently one of much interest and importance, but being compiled in the Dutch language it is of little value to English readers.

PUBLICATIONS RECEIVED.—*Journal of the Royal Agricultural Society of England*, March 31, contains an article and Part III. of an important paper on "Flower and Fruit Farming in England," by W. E. Bear; as well as communications relating to "Hedges and Hedge-making," W. J. Malden.—*Journal of Botany*, April, including "Notes on Mycetozoa," by Arthur Lister; "Botanical Excursions in Donegal," H. C. Hart; "Relationships of the Indefinite Inflorescences," E. A. Newell Arber; "Alabastra diversa," Spencer Le M. Moore; and "Merionethshire Mosses," J. E. Bagnall, &c.—*Experiments with Crops and Stock in Cumberland, Durham, and Northumberland* (Annual Report of the County Councils for 1898), by William Somerville.—*Observations on the Cultivation of Roses in Pots*, William Paul (eighth edition).—*Pharmaceutical Journal*.—*Agricultural Economist*.—*The Strength and Decay of Nations*, by Giles Andrew Daubeny (*Timber News* Offices, Liverpool and London; and Simpkin, Marshall, Hamilton, Kent & Co.) These are two articles on Forestry and on British Forestry, the former having previously appeared in *Nature Notes*. The author's opinion is that "forests are destroyed with most disastrous results, involving the ruin of climate favourable to life, and to the impoverishment and eventual downfall of once powerful nations.—*Agricultural Journal, Cape of Good Hope*, March 2, includes various reports, a letter from Mr. Mayer, of Stellenbosch, recommending, on the authority of M. Henri Coupin, of Sarbonne, cyanide of potassium, solution of 1 per cent. strength, as a remedy for Phylloxera on Vines; a paper on the "Science of Fruit Tree Fruitfulness Simplified," and similar communications.—*Tropical Agriculturist*, March, with articles on Tea-bushes and their Enemies, Planting in Perak; Planting Coffee, Rubber, Tea, Cotton, Sugar, &c., in Brazil; Vanilla, Plantain or Banana-meal, and so on.—*Indian Gardening*, March 16, and Index to vol. iii., July to December, 1898.—*Annual Report on Government Gardens and Parks in Mysore*, for the year 1897–98. "The information furnished as regards the cultivation of hybrid Coffee and of Potato-tubers deserves particular notice. The season was good, and garden culture on the whole successful. It is satisfactory to note that attention is paid to sericulture."—*Annual Report of Botanic Gardens, St. George, Grenada*, 1897, by W. E. Broadway, Curator. This is satisfactory on the whole, though the absence of the Curator was much felt while he was officially visiting the peasant proprietors of Carriacou and the Grenada parishes, examining the produce, and in a general way instructing those willing to receive hints concerning the founding and fostering of minor products and husbandry for pleasure and profit.—*Annual Report of the Secretary for Agriculture, Nova Scotia*, for 1898. A statement of work done during the year, and an abstract of the Reports of Agricultural Societies.—*Nova Scotia: its Agricultural Resources*, by B. W. Chipman, Secretary for Agriculture, Nova Scotia. A pamphlet "for agricultural emigrants who may be induced to look to Nova Scotia as a field for their labours." A useful map of the province is included.—*The 1899 Supplement to New Creations in Fruits and Flowers*, from Burbank's Experiment Farms, Santa Rosa, Sonoma County, California.—*An Apple Canker*, W. Paddock, New York Agricultural Experiment Station, Geneva, N.Y.—*Minnesota Botanical Studies*, Part II. (2nd series), February 22, contains articles on Seedlings of certain Woody Plants, Francis Ramaley; and Comparative Anatomy of the hypocotyl and epicotyl in Woody Plants, Francis Ramaley; Contribution to the life-history of Rumex, Bruce Fink; Observations on Gigartina, Mary E. Olson; Seed Dissemination and Distribution of Razoumofskya robusta (Engelm.), Kuntze, D. T. MacDougal; Constantinea, E. M. Freeman; Extension of Plant ranges in the Upper Minnesota Valley, L. R. Moyer; and Hepaticæ collected along the International Boundary, by J. M. Holzinger, 1897, Alexander W. Evans.—*Botanical Gazette* (Chicago, Illinois), March. This contains, among other things, Notes on the Structure of the embryo-sac in Sparganium and Lysichiton, D. H. Campbell; Geological Relations of the Vegetation of the Sand Dunes of Lake Michigan, H. C. Cowles; New Colletotrichum Disease of the Pansy, R. E. Smith; New Biennial, Fruited Oak, E. J. Hill; Wyoming Species of Antennaria and New Colorado Antennaria, Elias Nelson.—*The American Florist* (Chicago and New York).—*The Weekly Florists' Review* (Chicago and New York).—Among suggestions for useful horticultural appliances, we find here sketches of a telescopic "bucket," which can be extended for long-stemmed and contracted for small flowers; a "finger-knife" for severing the stems of Carnations and other plants, and consisting of a thimble, with a sharp blade set in the top; and a "smoker," contrived from second-hand stove-pipe.—*Gardening* (Chicago), March 15, with a good article on Freesias.—*American Gardening* (New York), March 18.—*The Florist's Exchange* (New York), March 18 (Special Spring Trade Edit.) and 25.—*Journal Horticole et Viticole* (Bordeaux), April.—*Semaine Horticole et Revue des Cultures Coloniales* (27, Rue du Chatelain, Brussels), April 1.—*Revue de l'Horticulture Belge et Etrangère* (Ghent), April 1, with descriptions and coloured figures of Azalea indica, "Ceres," and Ligustrum japonicum var.—*Geaschel's Allgemeine Gärtner-Börse* (Gera, Reuss), March 26.—*Wiener Illustrirte Garten Zeitung*, March.—*Möller's Deutsche Gärtner Zeitung* (Erfurt), April 1.—*Tijdschrift voor Tuinbouw*, April 9, 10, including a paper by L. A. Springer, and coloured plate of Rubus sorbifolius, and a Review of Horticultural Literature, by the same author.

AZALEAS.

AZALEA SINENSIS.—The beautiful seedlings raised by M. Anthony Koster are said to be hybrids between A. mollis and A. sinensis. There is clearly some blunder here, as these two names belonging to one and the same species, the correct name of which is Rhododendron or Azalea sinensis. The following extract from the *Botanical Magazine*, t. 5905 (1871) may be accepted as conclusive evidence on that point:—"Rhododendron sinense, Sweet, syns. R. molle, Sieb. & Zucc.; Azalea sinensis, Lodd.; A. mollis, Regel; A. japonica, A. Gray. Botanists are now pretty well agreed in considering that Azalea can no longer be considered a distinct genus from Rhododendron. . . . I have therefore followed the eminent Japanese traveller and botanist, Maximowicz, in assuming Sweet's old name of Rhododendron sinense for the Azalea mollis of more recent authors. R. sinense is a native of Alpine shrublands in Japan, and is also cultivated both in Japan and China, whence it was introduced into England, first in 1834, and again by Fortune in 1845."

Mr. Hemsley, in his *Index Flora Sinensis*, adopts the same view, and adds Lindley's Azalea pontica, var. sinensis, as a synonym (*Bot. Mag.*, t. 1253). The plant is unquestionably wild in China as well as in Japan, having been collected in Ningpo, Meichi, Kiangsi, Fokien, and Hupeh.

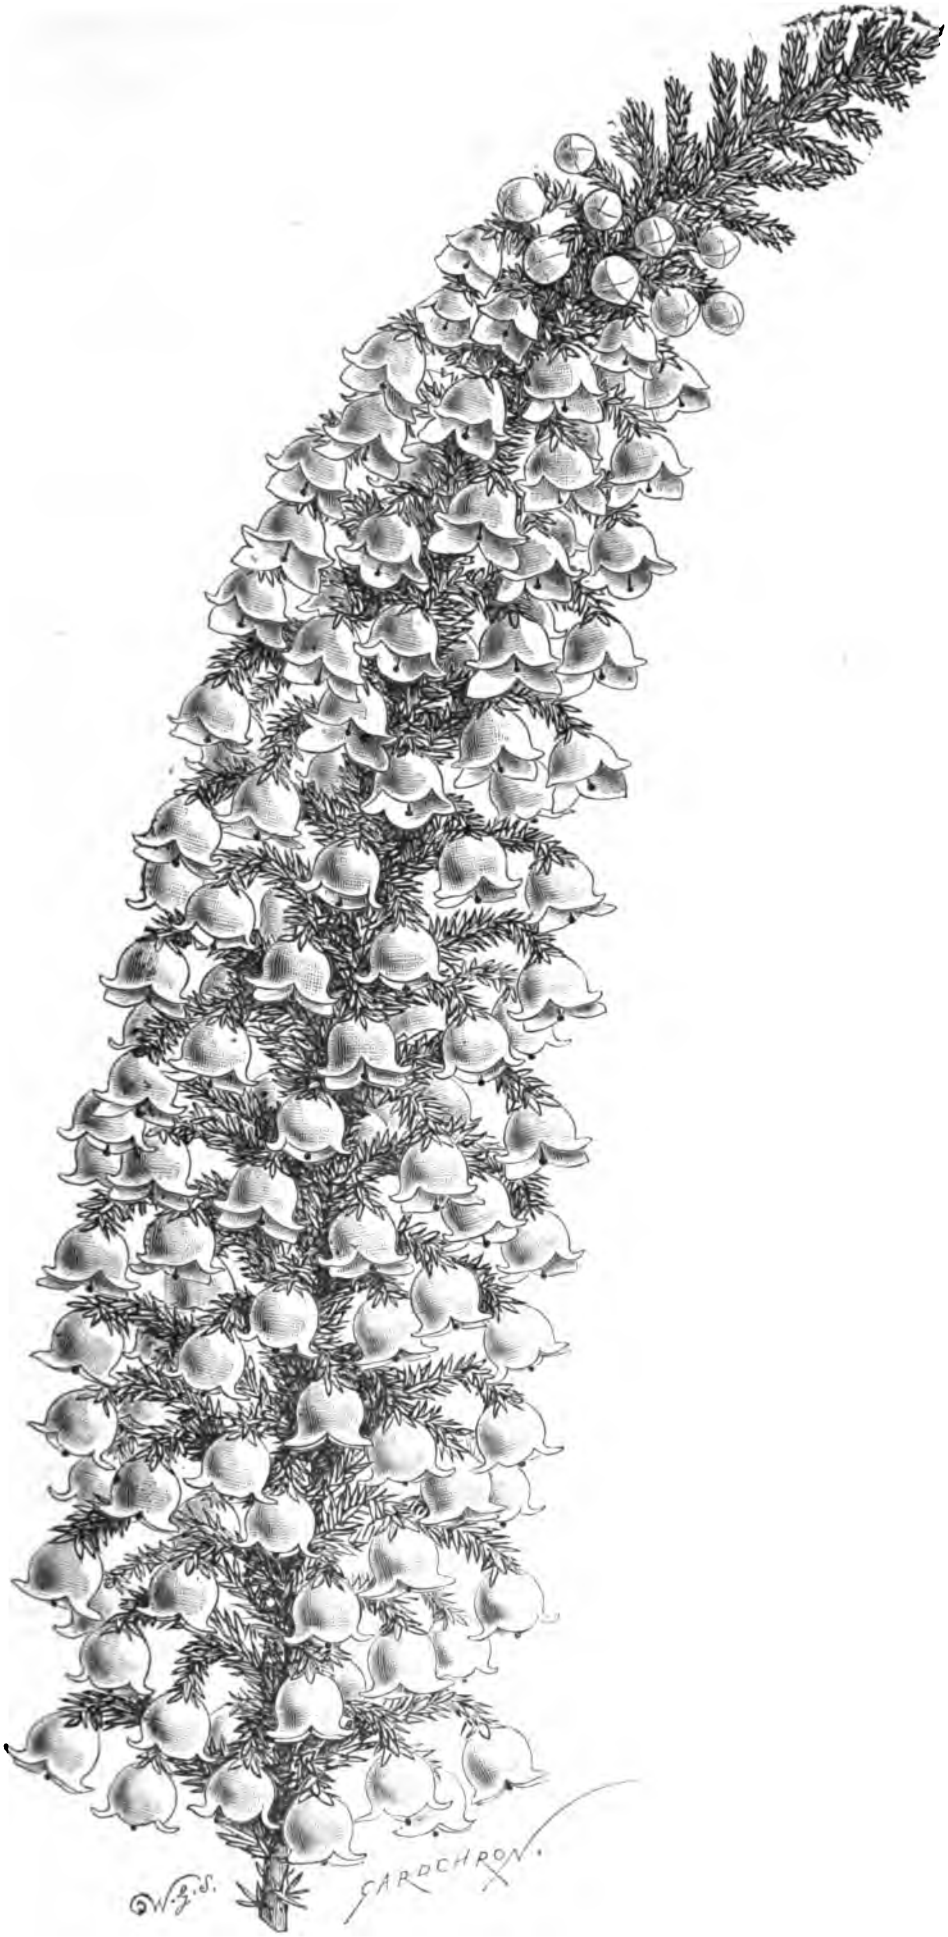


Fig. 87.—Erica propendens: colour of the flowers rosy-purple.
(See "Erica Chamissonis," p. 228.)

Probably the plant known as R. sinense was almost forgotten when it re-appeared twenty years later under its new name of Azalea mollis; and as there were known to be several coloured varieties of it, they have come to be looked upon as representing two distinct species. Whatever the origin of M. Koster's plants may have been, and I do not see any other species than sinense in many of them, they are clearly not hybrids, but colour forms of sinensis, unless he has used some of the "Ghent Azaleas" for his crosses. These have been crossed with R. sinense by several breeders, including Mr. A. Waterer and Mr. Isaac Davies. The Earl of Carnarvon also raised some hybrids between R. sinense and the North American R. viscosum. The Ghent nurserymen, especially M. Van Houtte, did much to improve and diversify R. sinense.

Ghent Azaleas are the outcome of various mixtures between the North American species, calendulaceum, viscosum, nudiflorum, &c., and the Pontic Azalea, now known as R. flavum. According to Loudon, Messrs. Lee & Kennedy were the first to produce hybrids from those species in this country. They were followed by Osborne, of Fulham, the Waterers of Woking, and Loddiges of Hackney, who enumerated 107 kinds in his catalogue nearly eighty years ago. A Belgian baker, named Mortier, also raised many hybrids and seedlings, and his work was continued by Van Cassel, Verschaffelt, Van Houtte, and others, with such success that the plants became very popular, and were known as Ghent Azaleas.

It does not appear to be generally known that R. sinense (molle) is hardy in the South of England; it is one of the most beautiful of the many fine Rhododendrons grown in the open air at Kew. *W. W.*

HOME CORRESPONDENCE.

OLD-TIME GARDENING.—Perhaps no reader of the *Gardeners' Chronicle*, when he perused the pages of the last issue, could have felt greater interest in the paragraph on "Loddiges, and Steam-heating," given on p. 213, than the writer of this note; for it called up old associations never to be forgotten. I was a gardener in those bygone days, and during the years of 1843-44, I had charge of, besides other plant-structures which were heated by hot-water pipes, a very large conservatory which was heated by steam, and in attending to my duties at all times and seasons I can call to mind, although so many years have gone by, the immense pleasure I felt in discharging the duties which devolved on me. I seemed to be in a veritable paradise, although my abode was but a bothy, and my wages twelve shillings a week. I can remember the inmates of this huge structure, some of which were 30 feet high, including some grand specimen Camellias, furnished in their season with hundreds of well-developed blooms, notably the "old double white," which was introduced into this country in 1824 as C. japonica flore-pleno alba; also Lady Hume's Blush, which was then a great favourite, as well as many others of different shades of colours. At the times to which I refer, this conservatory had been in use a great many years, and was one in which Sweet, the botanical writer, had laboured, perhaps before I had commenced my gardening career, which dates from 1832; but everything about the structure was in good working order. If my memory serves me aright, the boiler contained 500 gallons of water, and was furnished with steam and water-gauges, and all other required appliances. The steam-pipes were conveyed through a subterranean tunnel, and traversed a very considerable distance before they entered beneath the stone flooring of the conservatory. The heat was admitted to the house through numerous neatly-designed gratings fixed into Portland-stone pathways. How sweet was the atmosphere! how lovely were the numerous plants! what an enjoyable parade in winter and summer! *G. F., F.R.H.S.*

AMERICAN METHODS OF JUDGING THE CARNATION.—The American Carnation Society has lately held a convention, at which a new scale of points in judging was discussed and formulated. One hundred points is the maximum, and this number is divided as follows: colour, 25; size, 20; calyx, 5; stem, 20; substance, 10; form, 15; and fragrance, 5. This appears to be somewhat cumbrous to English tastes, but the justification is found in the fact that it appears to work well. Further, the convention takes cognizance of the nomenclature of the flowers, registering the names of new varieties, possibly with a view to prevent any confusion from synonyms; and it is intended to prepare and issue a complete alphabetical list of Carnations, with descriptions, and the names of the introducers. Something like this has been done in the case of both the Chrysanthemum and the Dahlia in this country, and seeing that the Carnation has become one of our most popular flowers, and having regard also to the fact that the National Carnation Society has now grown into an important organisation, it is worthy of consideration whether some court of appeal, such as that existing in the United States, should not be set here. There is, of course, an unwritten law of quality observed in this country, but nothing on the authority of the National Society has been set up. George Glenny's summary of qualities, excellent in their comprehensiveness, was drawn up some years ago, and was intended to apply only to exhibition flowers; since then the Carnation has become revolutionised, and an intelligent system of classification should be put forward. The idea is worthy the attention of the committee of the National Society. *Florist.*

EARLY POTATOS.—Already a seedling early Potato has been placed before the Fruit Committee of the Royal Horticultural Society, and has, of course, been remitted to Chiswick for trial. But the representative of one of our leading Potato firms recently made complaint that very early Potatos had little chance of distinguishing themselves at Chiswick when grown with a mixed collection of varieties, because they were not examined until a sufficient number of mid-season and later varieties were ready, and then the first earlier when lifted looked poor in comparison. I have expressed a wish, which I trust will be acted upon, that seeing what a wealth of late strong-growing varieties there are in commerce, and how important it is, not only for private work, but also for market purposes, that we should have the best possible of precocious varieties, the Potato trial at Chiswick next year should be limited to First Earlies only, and if so, I trust that a great effort will be made to obtain stocks for the purpose of every known good early variety in commerce. First early Potatos are largely lifted for use in an unripe condition. For that reason, one examination as to cropping capacity and size of tuber, should be made early in July, and a second and final one to test matured cropping qualities, and also cooked quality, some three weeks later. We should then have ample opportunity to discern how far the Ashleaf Kidney, for of this old variety, differences exist chiefly in name, has been ousted from its long proud position as a first early by newer varieties. *A. D.*

CAMELLIAS.—With reference to the paragraph of "E. H. S.," in your last issue, many of your readers who are not acquainted with the habits of the Camellia would be glad if he will kindly afford them information as to the best time for repotting, surfacing, and pruning the plants, these being matters not much noticed in calendarial instructions. Are all varieties equally well adapted for planting in borders? *R. C.* [Will some cultivator oblige by narrating his experience? Ed.]

SALADS IN ENGLAND.—Mr. Milne-Redhead, at p. 220 of the *Gardeners' Chronicle*, does well to ask why we so much neglect salads? I was once foreman at Sidmouth, when the hotel was a private establishment, nearly a quarter of a century ago. There was then no great difficulty in obtaining good salads there at this season, as we could winter soft bedding plants safely without glass protection. In many gardens I can give one cause why there is such a scarcity of salads at this season, and the fault is not the gardener's. Every frame and other glass protection is crowded with bedding plants, and without glass in many places salads cannot be grown satisfactorily. Much also depends upon the demand that exists, for those who have to provide a regular supply will be sure to have better materials than others who only have spasmodic calls made upon them. Then it should be remembered that a wet winter is more disastrous than a drier, though colder one, as so many of the Lettuce decay at the collar then, and are lost. In such situations as that of which Mr. Milne-Redhead writes, there should be no scarcity of Lettuces; but the question arises, do the persons interested at Sidmouth trouble about a supply? The soil of the garden is good, and the situation of the garden one of the best I ever was in. Many growers will admit that Lettuces are not a safe crop in some localities. This year we planted out some thousands of plants on sloping borders early in October, and now we have only a few hundreds left, owing to the excessive moisture. It may be asked, Why plant out Lettuces in the autumn, when failure is so probable? Those plants that are saved grow away quickly in the spring, and in hard weather it is easy to cover them with dry bracken or long litter. We cannot give all our Lettuces the protection of glass, nor is it desirable, as the spring plants in the open, when they tide over a winter, are most valuable. I am well aware that many growers sow a large area of Lettuces in August, and leave them in the seed-beds until March or April; but of course this does not provide a winter supply, though they will be valuable for spring use. But there have been great losses amongst even these, owing to new growth having been made early, and subsequently injured. But we are not totally dependent on Lettuces for salads, though there is nothing equal to them in quality. A fair salad may be made with such things as Endive, Dandelion, Chicory, and Celery; the first three, when well blanched, are not at all bad. For use in a salad, when all is cut up in the salad-bowl, for home supply I have frequently sown Lettuce seed thickly, and cut over the plants in a young state. Endives winter well; and there is no difficulty with the Batavian varieties. These plants should be plentiful in Devon and Cornwall, and with glass protection such Lettuces as Golden Queen, sown early in the year, will be ready in three to four months from the time of sowing. I fear we do not pay enough attention to winter salads, and to obtain them (Lettuce especially) needs considerable care. The season has been a most difficult one, but we certainly could grow more salads by giving them timely shelter. The best measure of success can only be obtained in our variable climate by the use of glass protection, but good judgment in sowing and planting is also required, as the plants do not winter well if too large, and small ones if late sown stand no chance. *G. Wythes.*

—— In an article in the *Gardeners' Chronicle* of April 8, p. 220, signed "R. Milne-Redhead," concerning English salads, the writer prefaces his remarks with the question, "Why do English gardeners so much neglect salads?" The writer then mentions a favourable locality in southern Devon where early salads would be easy to grow compared with other less favourable districts. Yet, notwithstanding the magnificent surroundings of choice trees and shrubs, flowering and otherwise, with conservatories, kitchen-gardens, and other accessories that go to make up a modern hotel, R. Milne-Redhead deplores the absence of the humble salad. As a case in point, R. Milne-Redhead mentions the north of France, where the climatic conditions are much worse than in Devon, and yet salads are grown in quantity, and served at each meal. Ah! that is the point, as undoubtedly the demand would be greater there than in England; or perhaps the growers in northern France can make a better turnover by growing salad than by other branches of gardening. If there really was a good and general demand for salads here at remunerative prices, there can be no doubt that hotel-keepers, who are usually keen men of business, would be equal to the occasion, and would supply good salads. Lest it should be understood by the uninformed that English gardeners cannot grow early salads, I give a list of salads with which I am supplying my employer's table, viz.—Mustard-and-Cress, Cucumber, Lettuce, Radishes, Celery, and Chicory; but then early salads are in especial request, and they may be grown under less favourable atmospheric conditions than those which obtain in South Devon. *D. C., Hanger Hill House, Ealing, W.*

PRIMULA OBCONICA AN IRRITANT.—I dare not let the foliage nor even the flowers come into contact with my skin. The irritation thus caused has been most painful, and has continued for several days. The affected skin has the appearance of blisters, and eventually peels off. I have tied a piece of linen, or put a piece of sticking-plaster over the place when it was possible, to keep it from being rubbed, which increases the irritation. *J. Mayne, Bicton Gardens, Devonshire.*

PRIMULA SINENSIS LEAVES CAUSING IRRITATION TO SKIN.—In the *Gardeners' Chronicle* of April 1 there is a notice of the above by Mr. J. R. Wilson. A few years ago, when the discussion was renewed about the skin-irritation caused by P. obconica, a gentleman from the north wrote to me, stating that he knew of a case in which this nuisance was caused by the leaves of Primula sinensis. He said he had no doubt about it, as the person who had been afflicted had no P. obconica, but only the P. sinensis. I then brought the fact to the notice of Dr. Masters, with whom I had been in correspondence about P. obconica. He replied that the fact, if it was a fact, was new to him. Now, is it not possible that there may be some source of error regarding the irritation caused by the leaves of P. sinensis? When I was living in London, a few years ago, during cold weather, both my hands became covered with a most irritating sort of eczema. The skin of both hands, palms, and backs, between the fingers and round the wrists, became dry with cracks in various places, and the itching was so great that I felt I could tear the skin off my hands with my nails. This irritation prevented me from sleeping. I consulted a docter, who told me the best thing for that sort of ailment is "Burroughs and Welcombe's Icthyol ointment," a black sort of ointment, with a peculiar odour, sold in tubes. I got some, and rubbed it every night on my hands. It did not cure the affection, but it mitigated the irritation very much. After this long story, what I am coming to is this: I had neither P. obconica, nor P. sinensis, indeed no plants whatever. In my opinion the dry, rough, and irritating affection of my hands, was the result of the cold and dry N.E. wind, for when the wind changed to a warm and moist S.W., all the affection disappeared. Here in Worthing this season, the same thing happened on two occasions. When it blew N.E., the hands became rough, sore, and extremely itchy. When it blew S.W., the whole thing went away. In this case also, I had neither of the Primulas. I write all this story because possibly the case referred to by Mr. J. R. Wilson, may be quite unconnected with any handling of Primula sinensis. *E. Bonavia, M.D.*

MARKET GARDENING IN THE CHANNEL ISLANDS: JERSEY.

(Concluded from p. 222.)

Mr. Philip le Cornu's Nursery.—The first feature one sees upon the nursery at Almorah is a broad walk which runs through the grounds. On either side are borders filled with choice trees and shrubs. This avenue, for so it really is, includes many fine specimen Coniferæ, and at stated distances are pairs, one on each side, of Silver Limes, Copper Beech, Silver Maples, Tulip-trees, Golden Poplar, Purple Sycamore, Cercis Siliquastrum, Pawlonia imperialis, Ailanthus glandulosa, Prunus Pissardi, Mountain Ash, and other species of ornamental trees, which are well established. Hardy shrubs are grown in very large quantities. Roses and fruit-trees are the specialties grown most extensively. Many of the climbing Roses are worked on the French Grifferaie stock, but for dwarfs and Teas the seedling Briar and Manetti stocks are freely used. The whole of the stock was in capital condition. Such varieties as Maréchal Niel, W. Allen Richardson, and Gloire de Dijon are grown in greatest numbers.

Much of the nursery ground is divided into squares of good size, having a row of close-growing dwarf Poplars planted between them, to afford shelter, and break the force of the winds; for here the winds are sometimes very keen and strong. In such divisions, Pear, Apple, Plum, and Peach-trees are grown, and they are in most robust health, the pyramids and cordons being all that could be desired. Where it is possible, I would advise the planting of cordons. If there be only room for one or two, use the space for just that number; but if a good length of wall needs to be covered in this way, then plant a dozen trees of a sort, and even more if it is convenient. Do not plant a dozen different sorts, so that all will be represented by a single cordon.

It is better that cordons should lean away from the sun rather than towards it; by this means the wood generally receives a greater amount of sunshine, the fruit is the better exposed, and ripens more regularly. Some of the cordons had ripening fruits upon them, but these are precocious, and it is after removal that they promise an abundant return. Pyramidal trees were also very interesting; these are almost all four years old—stout, well-formed trees, with good shoots and laterals. Well-formed standard fruit-trees were numerous; while of Peaches and Nectarines, Cherries, &c., the stock is very large, and the trees are in good heart. Cordon Gooseberries were a feature that looked very well. A great number of sorts of these are grown, and a selection can always be made of the best.

It was interesting to notice the various systems of training Mr. le Cornu had adopted: the oblique cordons on walls and wire fences, the horizontal for the margins of beds and borders, the upright and the diamond-fence pattern for various positions.

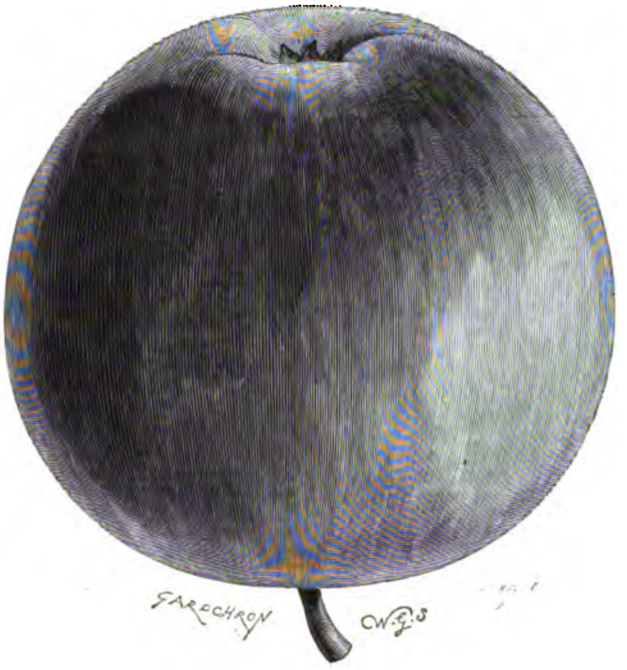

Fig. 88.—A good market apple, "Barnack Beauty."

My attention was directed to a method practised here in the matter of budding Peaches. When a bud has been inserted a Plum-bud has also been put in the same stock a little above that of the Peach. Rarely do they both fail, and sometimes both buds would take; it is then an easy matter to rub out the growth of the Plum, and preserve that of the Peach. This no-risk system is practised here in the case of many other fruit-trees and shrubs.

Herbaceous plants are given considerable attention. A large quantity of Dahlias are grown.

There is a large Spanish Chestnut-tree said to be 190 years old. It is said that the tree was planted by a silk-weaver from Spitalfields, one of the Huguenots who had fled from France, settled in London, and made a fair competency. Afterwards the family came to Jersey to reside, and brought from London a Chestnut which was planted, and has grown thus vigorously.

Of singular interest is a border we noticed, for in it each plant is a specimen many feet through, and in many instances are 6 and 8 feet high. Such specimens were Eulalia zebrina and E. gracilis. Arundo Donax variegata, many Bamboos of sorts, Phormium tenax, Chamærops excelsa, and Musa Ensete with a stem 4 feet in circumference, and leaves 8 feet in length. This Musa had remained out all last winter, with a little protective material wrapped round it.

[*From a Special Correspondent.*]

COLONIAL NOTES.

AUSTRALIAN BLACKBERRY-LAND.

Blackberries are so intimately associated with leafy hedgerows in English country lanes, that the idea of their growing in rich luxuriance in a land where the order of natural history, as known in the Mother Country, is popularly supposed to be reversed, where the stones of Cherries grow outside the fruit, and trees shed their bark instead of their leaves; yet there is nothing strange or incongruous in English wild fruits thriving in a country where every description of fruit and flower known in Great Britain thrives in perfection. The Sweet-briar, such a favourite in English cottage-gardens, grows so rapidly in Australia as to become an agricultural pest; and in parts of New South Wales the Blackberry is so prolific that the fruit is gathered by the ton, in place of the bushel or hundredweight with which English Blackberry-gatherers are familiar. The Blackberry is finest and most abundant on the coast a few miles south of Sydney; and Bulli, one of the leading coastal townships, inhabited chiefly by miners employed in the neighbouring collieries, is rapidly becoming a centre for the annual export of many tons of the delicious fruit. Rising gradually from the coast are the extensive Illawarra mountain ranges, and in not a few places on the slopes of these, on the lofty summits, and in clearings, the Blackberry bushes occupy many acres of ground. Paddocks which have been cleared and fenced, for cultivation or pasturage, offer no bar to the advance of the brambles. In more than one instance owners of land have long since ceased to fight the growth, which even bush fires but temporarily retard, so find it more congenial to lease their holdings for a small rental to the pickers, who, as a rule, have anything but an easy time of it. The bushes grow in a most irregular way, presenting in most cases a compact mass of Thorn and Briar many yards deep and several feet high. To reach every part of this mass of entanglement is the Blackberry picker's aim. Yet he succeeds in doing so, and may spend a day at one spot, forcing his way through the bushes as best he can. Generally, he will cut a narrow track to the heart of the bushes, and, establishing a centre at that point, "work" the bushes cleanly and systematically. Billies, buckets, and tins receive the fruit, which may then have to be carried some distance, perhaps right into the township, before being disposed of. Most of the Blackberry pickers are coalminers, and they have the assistance of their wives and families. The systematic gathering of the fruit commenced a few years ago. In 1894, 4 tons of Blackberries were sent by rail from Bulli to Sydney. In 1895, the quantity was 17 tons; in 1897 it had risen to 28 tons; in 1898, to 35 tons; and this year it is expected to reach 100 tons. The Blackberries are purchased, as they are picked, by a local dealer, who finds the demand already exceeding the supply. The berries are collected in carts stationed at suitable points, and sent, packed in tins, to Sydney. In some instances, 30*s*. per ton is paid for the right of entering lands and picking the fruit. Carting is estimated to cost 10*s*. per ton, and £9 6*s*. per ton is paid the pickers, being at the rate of 1*d*. per lb. That there are some smart pickers in the district may be gauged from the fact that the net gain to one family in a single fortnight has been £6. Another good family of pickers has delivered 400 lb. weight of fresh Blackberries, the result of one day's work. With the exception of Western Australia and Queensland, the bulk of the jam made from the Bulli Blackberries is consumed in New South Wales, the duty on sugar prohibiting much export. Allowing for evaporation of the water in the fruit, it is computed that one ton of Blackberries will turn out about 1¾ ton of jam, or 4,000 1-lb. tins. The greatest demand for Blackberry jam appears to be in the Newcastle district—the Australian "black country," and chief source of coal supply in the southern hemisphere. *A Correspondent.*

APPLE "BARNACK BEAUTY."

The variety of Apple, Barnack Beauty, is known to a number of gardeners, and more especially to such as cultivate Apples for market purposes. Indeed, it was to mark the Committee's sense of its usefulness in this respect that the variety was given an Award of Merit. The fruits are medium in size, or occasionally larger, greenish yellow in colour, streaked with red. The flesh is very firm, and the fruits may be kept until April or even May, and they are very valuable for kitchen use. The tree is a great bearer, and is described as upright in habit, especially when grown as a pyramid on Crab or Paradise stocks. It also forms a good medium-sized standard. The fruit sketched by our artist, and shown in fig. 88, were staged at the Drill Hall, March 14 last, by Mr. Gilbert, Dykebourne House Gardens, Lincolnshire.

LAW NOTES.

INLAND REVENUE *v.* TREEBY.

At a meeting held in Manchester, at the warehouse of Messrs. Wm. Clibran & Son, on February 23, a communication (a copy of which is given below), received by Mr. E. Collins through Sir John Wm. Maclure, Bart., M.P., was read.

Considerable discussion ensued, but eventually, on the proposition of Mr. C. Noyes, it was agreed that the appeal entered by Mr. Treeby should be withdrawn. It was thought that the view taken by the Treasury was guiding, if not wholly satisfactory, and would enable members of the trade to understand their position in taking contracts in the future, where the services of a man were required most days of the week throughout the year. The view taken, in the face of the letter, was that it would be a mistake to continue the proceedings.

The lateness of the date in sending you this communication has arisen, firstly, that the sanction of Sir J. Wm. Maclure had to be obtained for the publication of the Treasury letter; and secondly, in a letter received from the solicitor to the Nursery and Seed Trade Association, it was thought advisable not to give publicity to the Treasury letter until several points were made clearer, and steps were being taken to get a further opinion from the Treasury.

It may prove of interest to those who have followed this case, to peruse the undernoted letter, &c.— H. Watkins.

Oldfield Nurseries, Altrincham, Apr. 6, 1899.

Treasury Chambers, Whitehall, S.W.,
February 20, 1899.

"Dear Sir,—I duly reported to the Chancellor of the Exchequer the representations as to the summons against Mr. Treeby which were made by you and the gentlemen who accompanied you on your visit to the Treasury on the 13th instant, and he has now received a full report from the Board of Inland Revenue on the subject.

It was clear, both from the papers you left at the Treasury and from what passed at our interview, that it is not so much the decision in the particular case of Mr. Treeby that has aroused the apprehension of the nurserymen, as the impression evidently current in your constituency, that the decision will lead to a change of practice by the Inland Revenue with regard to the Servant Licence which will injuriously affect nurserymen generally.

I am therefore to explain, in the first place, that your constituents appear to have entirely misunderstood the intention and the effect of the proceedings taken against Mr. Treeby. It is not the practice of the Inland Revenue, and there is no idea of making it the practice, to require a licence to be taken out for a jobbing gardener employed at several places, and working one or two days a week at each; but the case brought before the magistrates at Manchester was not one of this nature. The Chancellor of the Exchequer is informed that Mr. Treeby had contracted to attend to the gardens, greenhouses, &c., of a Mr. Estcourt, which are fairly extensive, and that one man was employed for practically the whole of his working time every day on the work. It would be impossible to make a distinction between a man so employed and the ordinary private gardener, who is engaged on precisely identical duties for the same or perhaps a smaller number of hours a week, and to say that the latter is a taxable male servant because he is employed directly by his master, but that a licence is not required for the former simply because he is engaged through a nurseryman. The case was clearly, in the Chancellor of the Exchequer's opinion, one where a licence was required, and he does not think that the action taken by the Board of Inland Revenue against Mr. Treeby was in any way contrary to the spirit of the law. As to the letter of the law, he cannot of course speak with authority. He himself sees no reason to question the correctness of Mr. Yates' interpretation of the Statute, but if the nurserymen are dissatisfied with the decision, they will of course be able to test it by proceeding with the appeal of which notice has been given.

One further point requires a few words of explanation. The original intention of the Board of Inland Revenue was to proceed against Mr. Estcourt before it appeared that the gardener was not directly employed by him, and that Mr. Treeby was concerned in the matter; but Mr. Estcourt explained that his reason for not taking out a licence was that he was not the employer, as he hired the man. This was, technically, a sound defence, as it is enacted by 32 & 33 Vict., chap. 14, section 19, sub-section (4), that 'every person who shall furnish any male servant on hire shall for the purposes of this Act be deemed to be the employer of such servant.' The proceedings against Mr. Estcourt were accordingly dropped, and Mr. Treeby was asked to take out a licence. This he refused to do, and the Inland Revenue had accordingly no alternative but to prosecute him, if they were not to lose the duty on a man who was in all essentials Mr. Estcourt's private gardener. The Chancellor of the Exchequer would therefore suggest that you should explain to your constituents that, in a case similar to that recently tried, the Inland Revenue can under the law proceed only against the nurseryman, and not against the hirer of the gardener. It is for the nurseryman to make such arrangements as will prevent the cost of the tax ultimately falling upon him. In this connection, the Chancellor of the Exchequer asks me to mention quite a common case which seems to him exactly parallel. If a person hires a carriage and coachman for a period exceeding four weeks, the man from whom he hires them has to obtain licences, and it is left to the latter to recoup himself either by including the licence duty as a specific charge in the bill, or by making his terms sufficiently high to cover the payment.

"Yours faithfully, "L. N. GUILLEMARD.

"Sir John W. Maclure, Bart, M.P."

Re Alfred Taylor, Nurseryman and Florist, 62, Harrogate Road, Chapeltown, Newton, Leeds.

The first meeting of creditors concerned under this failure was held at the offices of the official receiver, Leeds, on Friday last. The summary of accounts filed by the debtor showed liabilities amounting to £239 11*s.* 7*d.*, and assets estimated to produce £92 19*s.* 6*d.* Eventually, the estate was left in the hands of the official receiver for summary administration.

SOCIETIES.

WARGRAVE AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

April 5.—A bi-monthly meeting of the above Society was held on the above date. Professor Groves, F.L.S., F.R.M.S., delivered a lecture on the "Structure of Flowers."

He traced the formation and growth of a flower from its embryo stage, stating that the coloured and honey-producing parts were necessary to encourage insects to visit them for the purpose of fertilisation. The colour of the corolla was due either to coloured granules or to fluid in the cells. The structure of the anther, with its enclosed pollen grains, and their manner of growth to fertilise the ovules, was clearly explained by means of diagrams.

Mr. W. Pope exhibited several pots of Amaryllis in full flower; and Mr. W. Fullbrook a large Deutzia, entirely covered with bloom. *H. Coleby, Hon. Sec.*

BOURNEMOUTH AND DISTRICT CHRYSANTHEMUM AND HORTICULTURAL.

April 6, 7.—This Society held an exhibition of Narcissus and other spring flowers in the Shaftesbury Hall, Bournemouth, on the above date, and it is to be congratulated on the excellence of the exhibits then brought together. With the exception of Messrs. Barr & Sons, who staged a fine collection of Narcissus (not for competition), the exhibits were entirely local.

Exhibitors in the cut-bloom classes for Narcissus showed excellently, and all of the classes were filled, so that the competition in most of them was keen. Some very fine bouquets and epergnes of Narcissus were shown.

The plant classes were for Narcissus, Hyacinths, Tulips, Lily of the Valley, Azaleas, Spiræas, Cinerarias, Primulas, Cyclamen, Deutzias, &c., and some capital examples of good cultivation were noticed.

Groups of miscellaneous plants formed a special feature, and those of the nurserymen's were admirable.

The Rev. G. H. Engleheart, Appleshaw, Andover, staged some of his unnamed seedling Narcissus, including an improved form of Sir Watkin, and one that is a cross between N. Horsfieldi and Polyanthus Narcissus Grand Monarque.

A fine two-coloured Narcissus, shown by Messrs. Barr & Sons, was named Lady Willis, in honour of the lady who opened the exhibition.

The non-competitive groups and stands of Narcissus, floral designs, and plants, helped to make up a successful exhibition. Although Bournemouth is filled with visitors, neither they nor the general public visited the show as it deserved to be visited.

WAKEFIELD PAXTON.

April 8.—A good attendance of members of this Society was present, on the above date, at the Strafford Arms Hotel, Mr. Swire presiding, to hear an interesting paper entitled "Orchids for Beginners," by Mr. John T. Barker, gardener and Orchid-grower to—Berkinshaw, Esq., Hessle Hall.

READING GARDENERS' MUTUAL ASSOCIATION.

April 10.—A lecture on "Climbing Plants" was given by Mr. J. Crooke, gr. at Forde Abbey, Chard, before the members on the above date, the President, Mr. C. B. Stevens, in the chair.

In introducing the subject, Mr. Crooke said that the subject he had selected was an old one, a very wide one, and it also included a wide range of plants. The gardener, he said, should cultivate taste as well as cultivate plants, and try to get away from old methods which did not always lend themselves to present-day needs; he also said that more use should be made of native climbers, for many of these would make the dull places of the garden beautiful. The following were briefly touched upon:—Out-door Climbers—the common Woodbine, Ampelopsis hederacea, Ampelopsis Veitchi, the most popular climber of the present day; Clematis montana, C. Flammula, Wistaria, Banksian Roses, Dunbar Roses, Cotoneasters, Jasminum revolutum, Loniceras, and Tropæolum speciosum. Tender Climbers—Ficus repens, one of the best; Bougainvillea glabra, Solanum jasminoides, Clematis indivisa, Tacsonias, and Fuchsias. Annual Climbers—Sweet Peas Canary Creeper, Mina lobata, Convolvulus, &c.

The exhibits included some flowering branches of Bridgesia spicata from Mr. Ward, of Crescent Road, and blooms of Rhododendron Veitchi lævigatum cut from a plant forty years old, and grown in a 14-inch pot in a cold greenhouse; also spikes of East Lothian Stocks, from plants taken from the open ground last autumn, planted in pots and flowered in cold pits during the winter, thus securing two distinct periods of blooming. These were staged by the lecturer, who also showed Apples Sturmer Pippin and Wellington, which had been kept in boxes placed in pits 4 feet deep in the ground during the winter. The fruits were firm and sound.

ROYAL CALEDONIAN HORTICULTURAL.

The blustering month of March this year robbed this exhibition of much of the brightness the Daffodils usually create. Few of the choicer varieties came out in the best condition; they need a more genial time than that vouchsafed this spring. Even so, the largest growers could manage to secure forty distinct varieties wherewith to win the 7-guinea Cup offered by Messrs. Barr & Sons.

The prize Cup was here, as also Messrs. Barr's representative, with a capital display of Daffodils and Narcissus, including their newest seedling, the Duke of Bedford; but the other notable growers were conspicuous by their absence, or were satisfied to show Narcissus, Daffodils, Tulips, Hyacinths, &c., in flower-pots as plants. Even were April to set in with genial mood, a fortnight must elapse before anything like a full muster could be made from plants grown in the open, north of the Tweed. Turning from the muster of cut blooms of Narcissus and Daffodils in vases, we found much to comfort us in the well furnished round and other tables of private growers and nurserymen, crowded with choice Orchids, sets of forced plants in bloom, in sixes; of stove and greenhouse plants, four ditto; of greenhouse and hardy Rhododendrons, Indian and hardy Azaleas; foliage plants, table-plants, Palms, Cyclamens, Japanese Maples, Hippeastrums, Deutzias, Gueldres Rose, Lilacs, Spiræas, Lily of the Valley, perfect in foliage and flower. Primulas such as Sieboldi, obconica, and sinensis; Polyanthus, common Primroses, Auriculas, and Alpine plants made a fine display.

There were also several exhibitors of twenty-four cut blooms of Roses, and no fewer than six exhibitors of twelve Maréchal Niel, three of which were excellent; three exhibitors of a dozen blooms of Gloire de Dijon, and several of dozens of Tea and other Roses.

Bouquets, hand, shower, and button-hole, and sprays, were very choice.

The dessert consisted of one Pine-apple, two exhibits of each six pots of Strawberries, three dishes consisting of thirty ripe fruits each, the best of which were Royal Sovereign; three exhibits of Black Grapes, two bunches each; and a bright muster of dessert and culinary Apples, among the finest dishes being Normanton Wonder, Bedfordshire Foundling, Winter Pearmain, Winter Juneating, Hormead's Kernel, Pomona, Galloway Pippin, Bramley's Seedling, Newton Wonder, Hoary Morning, Loddington, Green Loddington, Striped Beaufin, Gloria Mundi. Dessert varieties of very high colour, Ribston Pippin, Cornish Aromatic, Blenheim Orange Pippin, Reinette du Canada, and Keddleston Pippin.

Notwithstanding the late spring, vegetables were well shown, and the classes for amateurs and nurserymen were well filled.

Messrs. Downie, Laird, Dickson, Cunninghame, Gordon, Methuen, Wood, and others sustained their old reputation for Rhododendrons, Azaleas, hardy evergreens, shrubs, Conifers, Ferns, Palms, &c. While Mr. McIntyre, the gr. at The Glen, was most successful, as usual, in all the classes in which he competed, his muster of four fragrant Rhododendrons were examples of perfect culture. These plants were 1 yard or more in height and diameter, and comprised the following varieties:—Lady Alice Fitzwilliam, Princess Alice, fragrantissimum, and Duchess of Edinburgh.

Among the principal prize-winners were Mr. McIntyre, The Glen, Innerleithen; F. Nicoll, Craigowan, Perth; Geo. Wood, Oswald House, Edinburgh; Geo. Chaplin, St. Leonards, Dalkeith Road, Edinburgh; David Murray, Culzean Castle Gardens; Geo. Mackinlay, The Gardens, Wrest Park, Bedfordshire; D. Kidd, Carberry Tower Gardens, Musselburgh John Cairns, The Hirsell, Coldstream; R. B. Laird & Sons Jno. Downie, nurseryman, Edinburgh, and others, in the smaller classes for cut flowers, and for vegetables.

CHESTER PAXTON.

March 8.—The closing meeting for the present session was held on the above date, when Mr. Robert Wakefield (Newton Hall Gardens), read a paper on "Hardy Herbaceous Flowers."

Mr. Wakefield has of late years been recognised as one of the most successful cultivators of herbaceons Flowers in that district, and his paper gave evidence of a very intimate knowledge of the best varieties of these hardy flowering plants.

ANTWERP.

The Royal Horticultural Society of Antwerp is the first of the numerous societies of that town to commemorate the tercentenary of the birth of the great painter, Vandyck. The show was held in the fine Concert-hall of the Zoological Society, and opened on Sunday, April 9, to the public. It was feared that, owing to the height of the building, the fine specimen-plants would appear dwarfed, yet owing to the arrangement of the lateral galleries, this effect was not produced, and the general view was excellent.

The judging was completed on Saturday by a very numerous jury, which included M. F. Benary, from Erfurt; M. De Graaf, Leyden; M. Wilke, Rotterdam; M. Dudok de Witt, Amsterdam; M. Truffaut, and M. Duval, of Versailles; M. Arthur de Smet, M. Raphael de Smet, De Smet-Duvivier, M. Chas. Pynært, M. Ed. Pynært, M. Fierens, M. de Cock, and M. Leon le Bruyn. Messrs. Gordon, W. Cutbush, A. W. Ker, and F. Ker, came from this side of the Channel. M. de Bruyn, the Minister of Agriculture, was the President of Honour; M. Marc Micheli, of Geneva, the General President.

The members of the jury were received in the most cordial and hospitable manner, as is always the case in Belgium, being entertained at luncheon after the judging; received by the Burgomaster in the evening, and entertained at lunch by Madame E. Osterrieth in her palatial town house, the pictures and curios being much appreciated, as well as the kindness of the hostess and her lady friends in making everyone welcome.

The banquet to the jury was presided over by the President of the Society, Baron Osy de Zegwaart, and supported by M. Le Bruyn, the Minister of Agriculture, the Burgomaster of Antwerp, and many members of the Corporation, and the Secretaries of the show, Messrs. Verlinden and Anatole de Cock.

The special feature of the show was its picturesque arrangement, the floor of the large hall being laid out in the most natural manner with various collections by M. Servaas de Beucker, to whom the jury awarded a Gold Medal for his tasteful efforts.

Turning to the plants themselves, the platform of the hall was occupied with a collection of fine Palms, from M. De Cock, of Ghent, and included a fine piece of Ceroxylon niveum, Kentia, Phœnix, and Cocos, &c. This group was flanked by collections of hard-wooded plants, including collections of New Holland plants, the taste for which beautiful plants is reviving. In the collection of M. Bedinghaus, which obtained the Queen's prize, were fine specimens of Clianthus puniceus magnificus, Chorozema splendens, Cytisus floribunda, Mimosa armata paradoxa, Tremandra ericoides, and Pultenæa stricta.

In M. E. de Cock's collection was Genista præcox covered with white flowers.

M. Collumbien's group contained well-grown plants of Chorozema, Leptosperma bulbatum, &c.

A nice commercial lot of Pandanus Veitchi from Mr. Kuyk, Ghent, received a Silver Medal.

M. Vuylsteke showed nice lots of Azalea rusticana plena, pyramid and standard Azalea indica, and Amaryllis, for which collection he was awarded a Gold Medal.

Madame Osterrieth gained 1st prizes for a grand lot of Azalea mollis or sinensis, among which Anthony Koster was conspicuous; for fifteen Azalea indica in half specimens; and for twenty-five smaller plants, all of which were grown to perfection; for twelve Cliveias and for one specimen; for twenty-five Azalea mollis and twenty-five Primula obconica, this success was awarded a special diploma for its merit.

Messrs. R. B. Ker & Sons, of Liverpool, gained the Gold Medals for collections of forty Amaryllis and of twenty-five, the fine substance in the flowers showing its superiority in lasting quality over the old strains. Among the finest forms were Scarlet King, fine self; Virgin Queen, a magnificent form, white ground with carmine veins; Imperial, darkest crimson; Monarch, a grand dark red; White Lady, almost white; Apollo, red, with white stripes; Midas, white, with red veins, and many others, which made a fine effect, and which, though carried from Liverpool in flower, were looking well at the close of the show. The same firm was awarded a Medal for a sample of their strain of Cliveias.

M. Joseph Vervaene gained the 1st prize for new Azalea indica, the best of the twelve being Perle de Belgique, pure white, very double, and of fine substance; Irene de Meulemeester, double pink, with white edge; Spit Fire, a fine double crimson. The above are all acquisitions to our already large collection of Azaleas.

A very fine collection of Anthurium Andreanum varieties was shown by the Société Anonyme Horticole Gantoise of Ghent, and included pure white salmon, pink, scarlet, and crimson; this lot gained the 1st award, with the congratulations of the judges.

Cyclamen papilio were shown by M. Langhe Vervaene, one with a distinct yellow fringe, others were not so nice, having a faded appearance.

M. Arthur de Smet gained several awards for his fine strains of Anthurium Scherzerianum M. Dallière, a grand salmon-coloured form; Excelsior, a vivid scarlet; A. Scherzerianum album, and A. S. Souvenir d'Antoine Chantin, dark crimson, being among the best.

Roses in pots were well shown by M. Truyman Smets, and an honorary exhibit of white Lilacs, Roses, and Hydrangeas was awarded a Gold Medal.

The collection of Orchids arranged for effect was not so fine as might have been expected. M. Pauwels was awarded a Gold Medal, but the exhibit lacked colour.

M. Hye de Crom, of Ghent, gained 1st, for twenty-five Odontoglossums, which included Elegans, Hadweni, Vinckeanum, Ruckeri gracillima, gloriosum, and excellens.

For the most varied collection of Cypripediums, M. Moens, of Lede, was 1st, and his twenty-five included nitens, Moensii Harrisianum violaceum, Stella, and Van Imschootianum.

M. Peeters, of Brussels, showed a fine group of miscellaneous Orchids, among which were found Chysis bractescens, Cattleya Trianæi delicata, Odontoglossum pardinum, Zygopetalum × Perrenoudi superbum, Eulophiella Elisabethæ, Oncidium tigrinum, Angræcum sesquipedale, &c.

M. Vuylsteke carried off the President's prize for new Odontoglossums, viz.: 1, O. × spectabile, a cross between O. Harryanum and O. crispum, with violet-brown spots on a creamy-white ground, lip white at the tip, with a violet-brown base; 2, O. × vivicans (O. Harryanum × crispum) with brownish-red markings on a creamy-white ground; 3, O. × Loochristyense, a cross between O. grande and O. crispum, with large brown spots on a pale yellow ground.

The seedlings of M. Aaron were also worthy of comment—Cattleya La Fontaine (C. Mendeli × C. guttata), Louis Chaton (C. Trianæi and Lawrenceana), Lælia Latona inverta (L. purpurata and L. cinnabarina). The collections of M. Peeters were particularly well displayed. In M. Jules Hye's lot we noted Odontoglossum excellens superbum, O. elegans, and O. æmulus Holdfordianum.

Next to the Orchids was a small class for one seedling flowering-plant, which Messrs. Ker carried off with Amaryllis Magnificent, of large size and fine shape, colour reddish-crimson, with the tips of the petals almost white. The second was an Azalea of the linearifolia section. A most curious Cliveia, with green stripes in the centre of each petal was not placed.

The Late H. T. Soppitt.

One of the most distinct plants of the show was Anthurium Hookeri, with leaves 4 feet long, exhibited by the Comte De Kerchove.

In the group of Palms shown by M. E. de Cock, and which obtained the King's prize, were superb specimens of Ceroxylon andicola, and Caryota Cunninghami.

M. de Kuyk showed a fine plant of Brahea Roezli, as well as a superb group of Araucarias. Madame Osterrieth took several prizes for Azaleas.

A pretty lot of Citrus sinensis in fruit, and of Boronia heterophylla were shown by M. de Smet Duvivier.

Altogether the show was very successful, and the arrangement excellent.

ROYAL BOTANIC.

April 12.—On Wednesday last, in the gardens of this Society, at Regent's Park, was held the annual Spring Show. The display was probably as large as that in many preceding years, but the greater part of the interest it represented must be accredited to miscellaneous exhibits from members of the horticultural trade. Despite the efforts that have been made to revive these exhibitions from the competitive point of view, they continue to decline. In none of the competitive classes on the occasion under notice was there any competition, and throughout the exhibition there were but three exhibitors in those classes. The St. George's Nursery Co., Hanwell, who had some first-rate Cyclamens; Mr. Kelf, gr. to Mrs. Abbots, South Villa, Regent's Park, who obtained a number of prizes; and Messrs. Young & Co., Stevenage Nurseries, Herts.

FROM THE NURSERYMEN.

Messrs. John Laing & Sons, Forest Hill Nurseries, London, in a very attractive group of miscellaneous plants, included some pretty Boronias, several new varieties of Azalea indica, a variegated variety of Rhapis flabelliformis, various Cordylines, Codiæums, and Cliveias.

Excellent Mignonette in pots was shown by Messrs. Morle & Co., Finchley Road Nurseries, N.

There was one group of Orchids, and in this Messrs. B. S. Williams & Co., Upper Holloway, London, N., displayed fine plants of numerous varieties of Vanda tricolor. V. t. superba, and another named Gottschalkei variety were very beautiful; the distinct form insignis was also remarked. Phaius × Norman, and various Cypripediums were included.

Mr. Thos. S. Ware, in a moderate display of Narcissi and spring-flowering plants, included several little gems of some rarity, and a tiny plant in flower of Calypso borealis, an interesting little Orchid, figured in *Gardeners' Chronicle*, April 8 1893, p. 421.

Messrs. Barr & Sons, King Street, Covent Garden, made a fine display of Narcissus, although their collection at Ditton is scarcely in full flower. We remarked several blooms of the beautiful new bicolor trumpet Daffodil Duke of Bedford, and many popular sorts.

A collection of Narcissus blooms exhibited from the Emerald Isle by Messrs. Hogg & Robertson, 22, Mary Street, Dublin. was noteworthy. The colour, size, and substance of the blossoms were most satisfactory. The Tulips, too, were fine. It should be remembered that this produce is from Irish-grown bulbs.

Cinerarias were made a specialty by Messrs. Jas. Carter & Co., High Holborn, London, whose large collection of single-flowering varieties represented a strain with large, brilliantly-coloured blooms. The double varieties, that appear to obtain less general favour, were also well shown.

Messrs. Wm. Paul & Son, Waltham Cross, Herts, showed Camellias in pots, Roses, Cannas, and a most gay exhibit of Tulips, also in pots. The Tulips were of single and double-flowered varieties. Two new ones were shown—Murillo, yellow, semi-double; and Rosa Mundi, a single flower, deep golden-yellow, marked red, of very good form.

Messrs. J. Hill & Son, Lower Edmonton, made a fine exhibit of Ferns, the tinted Adiantums, and varieties of Nephrodium being most attractive.

Cut Roses were shown only by Mr. W. Rumsey, Joynings Nursery, Waltham Cross, but there were something like seventeen dozen blooms, and the colours were bright.

There was capital produce shown of Tomatos and Cucumbers by Mr. S. Mortimer, Swiss Nursery, Rowledge, Farnham. The Tomatos represented a variety Winter Beauty, a seedling from Conqueror. The Cucumbers were the variety Sensation.

Obituary.

H. T. Soppitt.—On April 1, 1899, died at his residence, 12, Glen View, Halifax, Henry Thomas Soppitt, who succumbed, after an illness of a fortnight, to an attack of pneumonia. Born in Bradford, June 21, 1858, he was only in his 41st year when he was taken from us, leaving the world poorer by the loss of an original worker in that department of natural science in which he had made for himself a name. The subject of the present notice possessed that untiring energy and never flagging perseverance which are so essential to those who would unravel Nature's secrets. A Yorkshireman by birth, he possessed the genial *bonhomie* and warm-heartedness of his race tempered by a natural diffidence of manner that made it impossible for him to hurt the feelings of anyone. Brought up in his father's business, he resided in Bradford until 1894, when he removed to Halifax. Compelled to earn his living by an uncongenial and poorly-remunerative occupation, he managed to acquire an all-round knowledge of natural history; entomology, geology, zoology, and botany were alike to him the objects of study, and the sources of enjoyment. Devoid of personal jealousy, and ever free to impart the information he possessed to others, it is no wonder he made many friends.

In 1886 he was President of the Bradford Naturalists' Society, and for many years he was on the executive of the Yorkshire Naturalists' Union. A pleasant writer, he contributed many articles on natural history to the local press, some of which, such as his "Rural Walks round Bradford," "The Flora of the Bradford District," &c., are worthy of a more abiding place in the literature of Yorkshire. His paper in conjunction with Mr. J. A. Carter, on "The Land and Freshwater Mollusca of Upper Airedale," and his article on "Fungi," in Lee's *Flora of West Yorkshire*, are of a more permanent nature. Fond as he was of all branches of natural history, it was as a botanist that he did his most brilliant work. Possessing a sound knowledge of the flowering plants of Yorkshire, he took a special interest in fungi. Some ten or twelve years ago he began the biological study of the Uredineæ, and it is from his experimental researches that we know the life-history of the several species which had previously either been shrouded in mystery or wrongly interpreted. For instance, prior to his work, the Puccinia and Æcidium on Adoxa Moschatellina were regarded as being of the same species, but he demonstrated that the Puccinia is a Mucipuccinia, and has no relation to Puccinia albescens, which is an Auteupuccinia with Æcidium, Uredo, and teleutospores on the same host-plant. Then he cleared up the life-history of Æcidium leucospermum, showing it to be an Endophyllum. He found its spores germinated as those of Endophyllum do, and that while they were without effect upon adult plants, yet seedling Anemones became affected with the Æcidium after infection, and that the fungus had nothing whatever to do with the Puccinia fusca which occurs on the same host-plant. It fell to his lot to be the first person to demonstrate a heterœcious Puccinia which has its Æcidiospores on a Dicotyledon; this he did in working out the life-history of P. bistort, by proving that its Æcidiospores occur on Conopodium denudatum. He attacked that complicated problem, the life-history of the Pucciniæ on Phalaris arundinacea, proving that the Æcidium on Lily of the Valley belonged to one of them, which he named P. digraphidis, thereby opening a discussion amongst continental botanists as to the relative value of these specific forms, which has hardly yet been concluded. His communications to the *Gardeners' Chronicle* were mostly upon plant diseases, the last being an account of his repetition and confirmation of Klebahn's cultures of P. Pringsheimiana on the garden Gooseberry. Lactarius involutus, Sopp., is figured in Cooke's *Illustrations*, t. 1194. Dasycypha Soppittia, Mass., is named after him, as also is the genus Soppittella, one of the Thelephoreæ. His last paper in conjunction with Mr. Crossland appeared in the January number of the *Naturalist*, and contained descriptions of several new species of Discomycetes. He was present at the last meeting of the British Mycological Society, of which he was one of the original members, last October, in Dublin. He was in excellent health, enjoyed the meetings and excursions, and the meeting of old friends. From what fell from him there, it was evident that a somewhat lengthy visit to Switzerland in 1897, with his friend Mr. H. A. Pawson, where he found an opportunity of studying the Swiss flora, was one of the red-letter periods of his life. He was buried at Ecclesbill on April 4, when most of the leading naturalists of Yorkshire were present. He left a widow and four children to mourn his loss. *C. B. P.*

B. STEIN.—It is only lately that we have heard of the death, on Feb. 27, of Mr. Berthold Stein, Inspector of the Breslau Botanic Garden, in his fifty-third year. Mr. Stein was an occasional correspondent of this journal, and was much interested in the Primula Conference, held some years ago under the auspices of the Royal Horticultural Society.

M. DELCHEVALERIE.—The death is also announced of another of our correspondents, M. Delchevalerie. He was, we believe, of Belgian extraction. He took a most prominent part in the development of horticulture in Egypt, and died, according to the *Revue Horticole*, at the age of fifty-eight at Chaumes (Seine-et-Loire), France.

THE LATE DOWAGER COUNTESS DE KERCHOVE.—In common with many English friends, we offer our respectful sympathy to Count de Kerchove de Denterghem, the President of the Royal Agricultural and Botanical Society at Ghent, on the death, at an advanced age, of his mother, the Dowager Countess. Visitors to the Ghent Quinquennial will remember the gracious hospitality in former years of the deceased lady, and many are familiar with the magnificent Azaleas exhibited by her, and with the famous winter-garden which forms so great a feature in the horticultural attractions of the old Flemish city.

MYSORE.

THE subjoined extract from Mr. Cameron's report on the Government gardens and parks in Mysore for 1897-98 is of great interest:—

Hybrid Coffee.—The possession of hybrid plants on several estates in Southern India now appears to be an undisputed fact. These new forms are reported to combine, more or less, the characteristics of Coffea liberica and Coffea arabica, and are only found in localities where the two species have been cultivated and propagated together. They have not been introduced by the planters as new varieties, and were unknown prior to the introduction of the West African species Coffea liberica. It is therefore reasonably inferred that these intermediate plants are true hybrids. The most remarkable thing about them is their immunity from Coffee-leaf disease, a condition which can only be attributed to enhanced vitality in the constitution of the hybrid. This is a discovery of much importance to the planter, and will encourage him to pursue operation of crossing on methodical lines, with a view to raising improved strains of seed, as has already been done in most of the chief products of agriculture and horticulture in Europe. What should be aimed at now is the systematic crossing and recrossing of different species and well marked varieties until a really good hybrid or cross is produced. With this object a small coffee-plot has been planted in the Lal Bagh. It consists of 135 bushes in two species and one variety. Most of the plants were of a good size when put down, and it is almost certain that a few of the Liberian and Maragogipe specimens will flower early next year, when crossing operations will be commenced.

A CORRECTION.—We are requested to publish the following letter:—"Will you allow me to correct an error, into which I have unwittingly fallen, in the present issue of the *Rosarians' Year-book*, and wherein I stated that Messrs. HARKNESS had succeeded to the business of Mr. MAY in Bedale. I am assured that this is not the case; the present firm of J. & A. MAY, of Hope Nurseries, continues the business, which was purchased by them from the late Mr. HENRY MAY'S executors about five years ago, and has not only been carried on by the MAY family for three generations, but is now in a flourishing condition. *The Editor of the Rosarians' Year-book.*"

ANSWERS TO CORRESPONDENTS.

ADIANTUM FRONDS TO PRESERVE AS DECORATIVE OBJECTS: *Aden.* The fronds must be carefully laid out on herbarium or blotting-paper, under pressure, and dried, changing the paper twice or thrice a week. After this part of the process is complete the fronds will doubtless have lost some of their green colour, and it will be advisable to afford them the desired tint with aniline varnish, using this in a very attenuated form, so as not to give the fronds an unnatural shiny appearance, or to cause the pinnæ to stick together. Having drawn them through a vessel containing the coloured varnish, let them be hung up singly on hooks in a cool dry-air place. When dry, repack carefully between sheets of paper placed between the covers of a book, or a pair of boards, and set aside for future use.

BEGONIA SOCOTRANA: *J. Wilkinson.* This species being not truly tuberous, must be rested by partially withholding water, and keeping somewhat cool, but not dried off like Begonias which possess tubers. A two months' rest is sufficient for this species, or the hybrids from it. Neither should the stems be cut close to the soil, but be pruned rather severely, say to one-half or two-thirds of their length. Repotting may be performed at the end of the resting term, and when a renewal of growth seems called for. The best resting-place is the coolest part of the stove or an intermediate-house. Tubers, if they form around the base, may be made use of for increase. The plant may be struck from cuttings of the young wood taken when this has acquired a certain degree of firmness. They need a bottom-heat of 75° to 80°, and to be kept close, care being taken to prevent damping off.

BOOKS: *W. R. R. The Culture of the Chrysanthemum* (Wells), is published by W. Wells, Earlswood, Redhill, Surrey. Price 1*s.* 6*d.*

CUCUMBER LOCKIE'S PERFECTION: *G. G., Kew.* The variety was raised by Mr. Lockie, gr. at Oakley Court, Windsor, and shown by him at the Royal Horticultural Society's meeting on June 12, 1888, receiving a First-class Certificate. It is a cross between Purley Park Hero and Verdant Green.

EUREKA WATERPROOF PAPER: *E. J. Ash, Bulawayo, Rhodesia.* The paper enquired for is sold by Mr. C. A. Christiansen, Norwood Green, London.

ISLE OF WIGHT: *Guernseyman.* (1) We do not know what chance you would have of getting employment there; the area is not large. (2) The *Gardeners' Chronicle* is circulated there, as well as in Bulawayo, from which place we have received an article from an occasional contributor.

JUGLANS REGIA VAR. RUBRA: *H. Dixon, Sydney.* The plant being of Austrian origin, may be procured at the nurseries (*baumschulen*) of Mr. C. Rosenthal & Söhne, Vienna; or of Mr. Rudolf Abel, Hietzing, by Vienna.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*F. M.* 1, Pachystachys asperula (Justicia carnea); 2, a Cestrum, send when in flower.—*F., Wakeford.* 1, Cyrtomium falcatum; 2, Diplazium diversifolium? 3, Davallia dissecta var. Mariesii; 4, Platycerium alcicorne; 5, Pteris longifolia.—*G. N.* A double variety of Narcissus incomparabilis, commonly called butter and egg.—*W. E.* What you send from Launceston, Tasmania, is a species of Trefoil closely allied, if not the same as our Strawberry Trefoil, Trifolium fragiferum.—*W. G., Brighton.* An exceptionally pretty form of Odontoglossum × Andersonianum.—*Oak.* 1, Eriobotrya japonica (Japanese Medlar); 2, Ilex aquifolium Hendersoni; 3, Ilex dipyrena; 4, next week; 5, Spiræa Thunbergi; 6, Arbutus Menziesii (procera).—*W. H. H.* Your Dendrobium is a very fine D. nobile, but not D. n. nobilius, which is much darker in colour.—*C. S., Ipswich.* The Fern is Blechnum corcovadense; 2. Daphne odora (indica).—*R. W. R.* The Dendrobium nobile is quite equal to D. n. nobilius, if not from the original stock.—*W. N.* 1, Dendrobium Wardianum; 2, Dendrobium crassinode Barberianum; 3, Dendrobium crassinode; 4, Dendrobium aureum (heterocarpum).—*S. K., Wellington.* The Orchid is Cymbidium pendulum. The scarlet flower Stenomesson coccineum.—*S. A.* Yes, British; Gagea lutea. We are delighted to see an old friend.—*W. A.* The plant is a Hibiscus, but we are unable to identify the species. It may possibly be an undescribed one. If it should fruit will you kindly send us a specimen.

POTATOS WITH SCAB: *G. H.* Information on this disease will be found in a report to the Royal Horticultural Society Scientific Committee, November 8, 1898 (see *Gardeners' Chronicle*, November 19, 1898, p. 372). The form of scab is somewhat different, but the treatment required is the same. As your Potatos are already in pots, try the effects of top-dressing with flowers-of-sulphur or kainit. Remove all scabbed tubers, they will never produce healthy plants.

VINE DISEASE: *D. B.* Probably the American mildew; spray with sulphide of potassium, as recommended to another correspondent.

VINES: *D. B.* The materials were too scanty for investigation, and you should send shoots and leaves of various sizes.—*One in Ignorance.* Your Vines are badly attacked with a fungus or mould. Cut off the affected shoots and burn them, and syringe with a solution of potassium sulphide and water, ½ oz. to a gallon of water.

COMMUNICATIONS RECEIVED.—H. de W., Ghent.—F. K., Liverpool.—Editor.—W. G.—C. W. D.—D. W.—Col. T.—Dr. P.—W. Jolland.—E. C.—W. Q.—E. S.—D. T. F.—R. D.—G. W.—H. T. M.—F. W. B.—W. G. S.—H. Cannell & Sons.—H. H. D'O.—Prof. Wrightson.—Director, Royal Gardens, Kew.—G. C.—H. W.

SPECIMENS AND PHOTOGRAPHS RECEIVED WITH THANKS.—W. E. G.—W. G.—J. B.—Fruit Grower's Year Book (Cable Office, Hatton House, Great Queen Street).

THE
Gardeners' Chronicle
No. 643.—SATURDAY, APRIL 22, 1899.

GLASNEVIN.

THERE are many botanical gardens in Europe and in Great Britain we may fairly boast of—Kew, and Edinburgh, and Glasgow, of Cambridge, Oxford, and Birmingham; but there is but one Glasnevin, and it is both from the natural and cultural points of view one of the most interesting and beautiful gardens in the northern world. There is no fact more apparent, or that strikes the historian or antiquary with more force than that, "history repeats itself," or, in other words, that old traditions of light and leading continue for ages to linger around or upon the self-same spot of ground. In this wise we are told that—

> "The literary fame of Glasnevin began at a very early period. There was a celebrated school of learning on the banks of the river Tolka, on the site of the present Glasnevin Botanic Gardens. It was founded by S. Mobi, or Mobhi, who died in the year 544.
>
> The names of several abbots, his successors, are known, such as Cealtrog, ob. 741, Elphin, ob. 753, Maoltuil, ob. 882. It was, as all schools of learning were at the time and for centuries later, a religious community. Fifty scholars lived in huts by the Tolka, on the west bank. The church was then, as now, on the east bank of the river. This school had the honour of educating S. Columba after he had spent some time as pupil in the school of Clonard on the River Boyne.
>
> After some years of evangelistic work in Ireland, S. Columba left his native land, and founded his great missionary college at Iona. From it, and subsequently from its offshoot at Lindisfarne, went forth, as is well known, that noble band of Celtic missionaries who spread the Gospel through a great part of England, and over much of the continent of Europe. Of one of those missionaries, the late learned Dr. Lightfoot, Bishop of Durham, after careful historical examination, declared 'Not Augustine but Aidan is the true apostle of England.'
>
> On August 31, 1895, a number of English churchmen proceeded to Lindisfarne, an island off the coast of Northumberland, on the 1343rd anniversary of S. Aidan's death, that they might see the spot where his missionary work for England was organised. Now this Aidan, first Bishop of Durham, was the fellow-countryman and pupil of S. Columba. It was S. Columba's zeal which inspired his, and there can be little doubt that much of the knowledge and culture associated with his work had their origin in the master's school at Glasnevin, on the banks of the Tolka.
>
> The literary fame which attached to Glasnevin in its early days revived in the last century. Thomas Parnell, the poet, Dean Swift, Addison and Steele lived there. There is reason to believe that Swift's celebrated *Drapier's Letters* were written at Delville House, Glasnevin."

The self same salubrity and native charm that tempted the early Christians in Ireland to settle beside the Tolka at Glasnevin, clings around the place to-day, and renders it so doubly attractive, and especially to those interested in botany or in gardening.

Our illustration (see fig. 90) gives a charming glimpse of the bog and water-garden, a never-failing source of delight from the time of Golden Marsh Buttercups, Primroses, Lilies, and Japanese Iris, until Marliac's exquisite rosy, sulphur, or white Water Lilies (Nymphæas) are in flower. I have seen Glasnevin at nearly all times and seasons, but never without instruction and delight, go when one may, from the earliest Aconite or Snowdrop to the latest of Christmas Roses or Chrysanthemums, and all you will wish for is more time in which to look and to admire. Outside or inside, it is all the same; all tastes are consulted, and all sorts of plants are well grown. The cool-house devoted to Ferns is now very attractive, containing, as it does, very fine examples of Cyathæa Smithi, C. dealbata, and Alsophila crinita, &c. In an adjacent house is a spendid collection of Sarracenias, containing not only all the wild species, but many hybrids reared here by Mr. F. W. Moore during recent years, and which vie in form and coloration with the finest of wild kinds. The beautiful S. Moorei × was one of the first hybrids raised in this genus, having been raised here by the late Dr. D. Moore prior to 1874 (*Gard. Chron.*, 1874, p. 702), and it still remains one of the best.

Another choice "pitcher plant" long grown here, is a fine form of Nepenthes distillatoria, scrambling like a Vine over the roof of the Orchid-house, its urns dangling gracefully overhead, and showing their crimson-red lids to great advantage. Cephalotus follicularis also grows well here in a cool-house, its clustered pitchers larger and more highly coloured than I have ever seen them elsewhere. Here, also, that rarest of all the Pitcher-plants, Heliamphora nutans, from Guiana is developing its classically-shaped urns; and there are Droseras of all kinds in profusion, and even Byblis and Roridula are represented by one or two of their quaintest forms.

I must not forget to say that one of the very few plants of Nepenthes Rajah now alive is at Glasnevin, and it was from this plant that the noble pitcher was cut which Mr. Veitch showed at the Drill Hall on the occasion of his lecture, and which was afterwards very artistically modelled for the collection at Kew. Here at Glasnevin also is the finest living specimen I know of Darlingtonia californica, having pitchers over 2 feet in height, with bloated tops and crimson-forked wings, that remind one of a cobra head when reared and excited, and about to make its deadly stroke.

The new succulent-house with its contents obtains a good deal of attention from visitors, who criticise the "Hedgehog-plants" or "fossils alive," to their heart's content. Some of the finer and rarer kinds were imported direct from Mexico and California, and are doing well in their excellent new quarters.

There is also here one of the best collections of Bromeliads, including many rare kinds; and these, varying so enormously as they do in size, form, and colouring, are well worthy of more extended culture and study. Some of these identical rarities were in the once famed Morren collection at Liège, and others were carefully selected from French and Belgian collections by Mr. Moore. It is one of the peculiarities of our insular prejudices that we do not cultivate Bromeliads more extensively, and especially the hardier kinds, which are so beautiful in leafage, and would lend themselves to room and window culture almost as well as the Aspidistra, and better than do many Dracænas and Palms.

I think it is to Glasnevin we must go in order to see Philesia buxifolia 5 feet high and 8 feet across! Such a specimen is, as I suppose, absolutely unique, and is always good to see, either with or without its drooping coral bells or flowers. This plant is a shrubby or non-climbing first cousin of the Lapageria, and its hybrid is Philageria Veitchi ×, raised at Chelsea, and remarkable as being the first bigeneric hybrid named in an intelligent and logical manner, as showing its dual parentage.

There is here a specimen of Araucaria Rulei, 20 feet in height, very fine Browneas, and in the Palm-house the great tropical Bamboo is luxuriant, reaching a height of 70 feet (fig. 91).

Most visitors note the superb specimens of Irish Yews, and the celebrated old Yew-tree walk, associated with the name of Addison, and beautifully figured in Dr. John Lowes' work, *The Yew Tree in Great Britain and Ireland.* The original Golden-Leaved Yew still exists here at Glasnevin.

We often hear complaints as to the difficulty of growing Daphne Blagayana successfully, but there is a clump or tuft here in the utmost health and beauty, at least 8 or 9 feet across, and bearing hundreds of its sweet white and dense-tufted blossoms. Mr. Moore tells me the only secret is good red loam and plenty of stones over its roots and branches, but I never see this charming shrub so luxuriant elsewhere.

The herbaceous borders are already flowery, despite the recent gales, and the hardy Ferns are uncurling their croziers on the rock-garden devoted to them, and there is a golden light on the Willow shoots, as seen against the grey-blue sky.

Beauty of form and colour everywhere; on gold-fruited Ivy, on tree-trunk, lichened-rock, and mossy-stem, but a glance at the dial says *tempus fugit*, and we pass on to where the Misleto hangs in great olive-green masses from the Pyrus and other trees, and admire once more the perennial beauty of the hardy Ericas so well represented here. One plant o E. mediterranea cannot be less than 10 feet high, and is very lovely in colour. E. vagans, ramulosa, or stricta, carnea in variety, and hybrida, all are here, and they are all beautiful all the year round. These hardy Heaths are so beautiful that the wonder is they are so seldom planted near rocks and stones, on banks, or even in shrub-beds, where autumn and winter effects are desired.

To leave Glasnevin without a word about the Orchids would never do, for they are here a specialty, the genera Masdevallia and Cypripedium being very fully represented, as also are those exquisite little waifs and strays in this order that the late W. Wilson Saunders and his henchman, Chas. Green, loved and grew so well. It seems a pity to me always when at Glasnevin, that the "Refugium Botanicum," or portrait gallery for inconspicuous or botanical rarities, was discontinued, but if you whisper that to the genial director Moore, and he thinks you are appreciative, he may untie his portfolios and show you Miss Shackleton's exquisite colour studies of these his favourite floral gems. Amongst many Masdevalls the rare and peculiar little M. ventriculata longicaudata is now in bloom.

One of the most distinct and remarkable, as well as one of the rarest of all known Orchids, viz., Moorea irrorata, was named in recognition of Mr. Moore's ability in connection with Orchids new and rare.

Glasnevin is indeed a garden to see, and see again and again, and much; indeed, most of its interesting richness and value is due to its present and previous directors, father and son, both of whom have worked well and nobly in the public service during the past half century or more; and to their high-toned endeavour is due the fact that Glasnevin holds its own amongst the highest and best of the botanical gardens of our time. *B.*

NEW OR NOTEWORTHY PLANTS.

THAMNOCHORTUS INSIGNIS.*

We take the opportunity of describing and illustrating (fig. 93) this species, as its branching spikes and shining pale chestnut-coloured bracts render it very attractive. It is a native of the southern portion of the Cape Colony.

ORCHID NOTES AND GLEANINGS.

CŒLOGYNE CRISTATA.

"One day," says Mr. Maries in a communication to the *Journal of the Royal Horticultural Society*, "I came across masses of Cœlogyne cristata [at Naini Tal] at an elevation of about 3000 feet. The ground was covered with frost at noon. The branches of the evergreen Oak were covered with Cœlogyne—rather a cold place. It shows how hardy the plant is."

Dendrobium Wardianum.

Each spring some of the newly-imported plants display occasional flowers on the growths made in the plant's native habitat which cause great admiration in the beholders, but which are not to be found subsequently. These abnormal flowers usually appear on very stout pseudo-bulbs, which, if the plant had been left undisturbed in its native home, would have produced a greater number of flowers, each proportionately smaller. In the case of the new arrivals, the stored-up energy necessary to perfect the larger number is thrown into the lesser, with the natural result that the individual flowers are more than usually large.

Captain G. W. Law-Schofield, New-Hall-Hey, Rawtenstall, reports some phenomenal blooms that verge upon 5 inches in diameter, with fine colouring. He sends us a flower in which the two dark-coloured blotches, usually seen in the species, are reduced to a few almost invisible purple lines just under the column. The tint of the disc is also different, being of a Buttercup-yellow instead of orange. In other respects the flower is that of a good ordinary form, segments white, with rosy-purple tips.

The next question is, will it remain constant? It is known that in the white forms of D. Wardianum, which also show a suppression of colour on the lip, the extent and intensity of the colour occasionally are found to vary in the same plant from year to year.

Captain Schofield mentions the fact that many growers fail to keep Dendrobium Wardianum in good condition for any length of time, and enquires as to the cause. Is too much or too little heat given?

The Dendrobiums of this class require a high degree of warmth, much moisture, and a bright light—even a good amount of direct sunlight when growing; but a rest, long, dry, and cool afterwards. Probably fruitful causes of the loss of these deciduous species of Dendrobes are too much warmth, and too close an atmosphere when they are not growing.

Perhaps some of our readers who have mastered the idiosyncrasies of D. Wardianum, so as to be enabled to keep it in unabated vigour for a number of years, will kindly describe their methods.

Dendrobium Ainsworthi ×.

It is interesting to read in the *Orchid Review* that this plant has flowered with W. Thompson, Esq., Walton Grange, Stone, among a batch of imported Dendrobium nobile. The artificially-raised Ainsworthi has thus its parallel in Nature.

Dictionnaire Iconographique des Orchidées.

The last two parts which have reached us contain coloured figures and descriptions of: Angræcum sesquipedale, Thouars; Cymbidium eburneo-Lowianum var. Armainvilliense, Cogniaux; Cypripediumexul, O'Brien; C. Morganiæ, Rchb. f.; Miltonia Roezli, Nicholson, var. alba, W. Bull; Oncidium varicosum var. concolor, Cogniaux, var. Rogersii, Rchb. f.; Trichopilia coccinea, Warscewicz; T. crispa, Ldl.; T. fragrans, Rchb. f.; T. suavis, Ldl.; Cattleya Maroni, Hort. Maron; Cochlioda vulcanica splendens, O. Froebel; Cyperorchis elegans, Blume; Cypripedium insigne, Wallich; C. i. nigrum, F. Desb.; C. i. Sanderæ, Rchb. f.; C. Zampa var. Eurydice, Cogniaux; C. Calypso Oakwood var.; Epidendrum falcatum, Ldl.; E. atropurpureum, Willdenow; Miltonia Binoti var. intermedia, Cogn.; Oncidium maculatum, Lindley; and Trichopilia suavis, var. alba.

Orchids at Clare Lawn, East Sheen.

The collection of Orchids belonging to Sir Frederick Wigan, Bart., is noted for the steady progress which it has made in recent years, and the number of fine varieties and hybrids added to it. At the present time an unique plant of Lælio-Cattleya × Digbyano-Trianæi, which was illustrated in the *Gardeners' Chronicle*, January 1, 1898, is now again in bloom. The flower has since that time improved in substance and in the depth of the bright rose-pink hue of its petals and finely-fringed lip. Few hybrids show the value of the hybridist's work better than this one, the second cross between Lælia Digbyana and forms of C. labiata, and raised by Messrs. Jas. Veitch & Son. In flower in the same house are plants of Dendrobium × Sibyl superbum (bigibbum × Linawianum); Cattleya × Louis Chaton (Trianæi × Lawrenceana); several home-raised Spathoglottis × aureo-Viellardi, with yellow flowers spotted with crimson; a well-flowered plant of Epidendrum Stamfordianum; Dendrobium fimbriatum oculatum, D. albo-sanguineum, and other Dendrobiums; and as instances of excellent culture, a plant of Cælogyne pandurata, growing on a raft measuring 5 feet by 2 feet, which had borne six noble flower-spikes; Dendrobium atro-violaceum with fourteen leading growths; the singular Megaclinium falcatum, with numerous remarkable flattened flower-spikes, bearing on each side rows of singular-looking flowers; and the tiny Eria extinctoria, which blooms here every year, is sending up its flowers at the present time. At one end of the house is a group of fine specimens of Oncidium ampliatum majus, laden with its bright yellow-coloured flowers.

The largest of the Cattleya-houses showed a group consisting of Cattleya Schroderæ, which is fast becoming a favourite; some good Dendrobiums, among them a fine form of D. × splendidissimum grandiflorum, D. nobile, Hutchinson's variety; the best form of D. n. Cooksoni, and some others. On one side a noble plant of Lælia cinnabarina with seven flower-spikes was remarked; the true Lælia præstans from the Downside collection—a very different flower from the modern importations of the plant; varieties of Lycaste Skinneri, including the pure white-flowered one; two plants of Trichopilia suavis alba, Aërides Warneri, and other rare plants.

The warm-house in which the Phalænopsis are cultivated, and in which more than 700 flowers could have been observed at one time, is a reputedly safe place in which to put any heat-loving plant. Suspended near to the door are two superb plants of Eulophiella Elisabethæ, a plant whose flowers are white, which the majority of cultivators fail to grow satisfactorily. The plants at Clare Lawn under Mr. Young's care are very vigorous, and carry leaves 3 to 4 ft. in length on old and new growths alike, and fine spikes of flowers. In this house, numbers of Cypripedium barbatum, thickly set with flowers, are planted on the stage in sphagnum-moss. Cypripedium × Henry Graves, in bud; C. Rothschildanum, with stout spikes; a lot of C. Lawrenceanum, C. Chamberlainianum; a fine plant of C. callosum Sanderæ, bearing two spikes; and some other species. In this house Vandas, Bolleas, Pescatoreas, and other plants of that reputedly delicate nature thrive.

The rockery, partly planted with Ferns and species of Ficus, is a much admired house at this season. On the highest points are placed great specimens of fine varieties of Cymbidium Lowianum. The plants are always grown in the position they now occupy, and in the winter are often subjected to a very low temperature for an Orchid, but without the least ill effect.

In a small house, containing some special plants, the rarer forms of Miltonia vexillaria, including the plant of the magnificent M. v. Memoria G. D. Owen, are thriving, and the last-named and some other plants sending up flower-spikes. Here, too, are a fine Miltonia Bleuana, two splendid plants of Cypripedium bellatulum album, fine plants in flower of Epidendrum × Endresii-Wallisii and E. Wallisii, and a large number of plants interesting and rare, or remarkable for fine condition; and especially a fine batch of unflowered Lælio-Cattleyas, stated to be of high reputation.

In the cool-houses Masdevallias and Odontoglossums make a good display, among the latter a very distinct hybrid called O. × Golden Sheen, with bright citron-yellow flowers, the segments having a white base, thin lower halves spotted with dark red; also a peculiar form of O. × Adrianæ, and a few other spotted kinds. Specially noteworthy were Nanodes Medusæ, Cymbidium Devonianum, with four stout spikes; Ornithidium sophronites, which was carrying thirty-six of its pretty scarlet flowers; and several plants of Cymbidium tigrinum, grown and propagated here from the original plant, that was acquired at the sale of the Day collection.

MARKET GARDENING.

HARDY FRUITS: THE PLUM.

(Continued from vol. xxiv., p. 380.)

Loudon, in his *Arboretum*, says the Plum is not indigenous to England; but in the 1855 edition of his *Encyclopædia* he states there are several varieties of Plum found wild in Britain, and I incline to that belief, as a form called the Bush or Waterloo-Mogul of East Kent, is common on the chalk hills of Kent around Wye and Brook, near Ashford, as well as on the cretaceous formation that stretches along both banks of the Lower Medway to Rochester, and these form the favourite habitat of the Sloe (Prunus spinosa); other counties may have this variety as a native. There is no doubt that the Plum, except in its confessedly Oriental varieties, is one of the hardiest of our fruits; and from a culinary point of view, next in utility to the Apple. I may show undue partiality, but maintain that there is a no more delicious fruit, produced without glass, or often even without the aid of a wall, than the old Green Gage, though that delicious fruit is considered by some as a simple wilding, because it makes a reliable and prolific tree on its own roots, but even when worked it is apt to drop its branches when heavily laden. No stone fruit has been so markedly improved as the Plum, and some sterling kinds have been added to our list during the last twenty years, especially among the

---

* *Thamnochortus insignis*, Mast., sp. nov.—Elatus, culmis erectis teretibus crassitie pennæ gallinaceæ albido-puncticulatis; vaginis culmeis circa 8 cent. long, arcte convolutis coriaceis apice laceris; inflorescentia feminea 5—30 cent. long, lineari, pluristachya paniculatim cymosa; spiculis singulis approximatis ascendentibus ad 3 cent. longis oblongis basi spatha lanceolata coriacea ferruginea spiculâ ipsa dimidio breviore suffultis; bracteis sursum increscentibus acutatis spathæ conformibus; floribus circa 5 mill.; segmentis externis lateralibus profunde alatis obtusis, cæteris minoribus oblongis; ovario obovoideo stylo simplici superato. Riversdale, coll. *Rust*, 399a! 406, 407!

Gages and profitable market varieties. The late Thomas Rivers may be credited with at least a dozen new ones, while our latest additions and novelties have reached us from Japan, and are included with the Cherry-Plums, being similar to the well-known Cherry-Plum "Prunus Myrobalana;" and if they succeed here, will precede, at any rate in earliness, our most precocious varieties.

The Sloe has been thought by some botanists to be the parent of our round Plums, but anyone with mouth awry (?) after tasting one will be slow to think so. The oval or egg-shaped kinds are referred to an oriental progenitor. As, however, this fruit varies greatly from seed, I think we need not go so far to account for the many sorts now in cultivation, though history tells us various kinds of Plums were introduced about the time that the English, under Henry of Lancaster, were driven out of France, not long before the war of the Roses had broken out, arresting civilisation and progress for nearly a quarter of a century. Without romancing I will suggest that a gardener-soldier brought home some Plum-stones from the plains of Orleans, and sowed them on his return to England; while at the time of the Crusades we probably got the Eastern sorts, either through Italy or Spain.

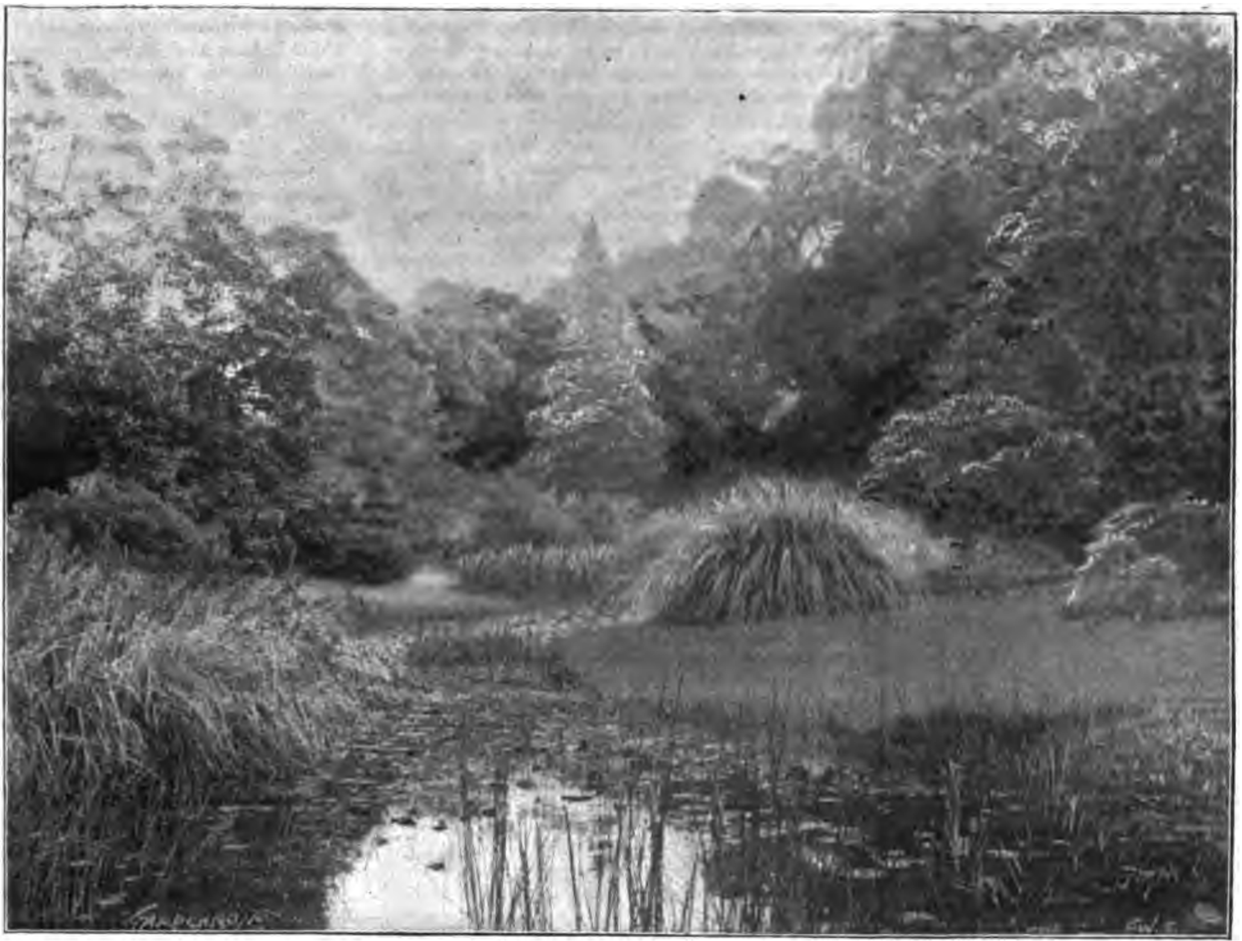

Fig. 90.—The "People's Garden," Botanical Gardens, Glasnevin. (See p. 241.)

We know the Gage Plums are called in France "Reine Claude," through having been introduced into that country by the Queen of Francis I., named Clauda or Claude; while its current English name is derived from the family cognomen of the Gages, who first introduced and cultivated it here. The celebrated Thomas Cromwell introduced in his commercial career many kinds during the early part of the reign of Henry VIII.; while the Damson, as its name imports, reached us from Damascus, hence Damascine, now Damson.

As a culinary fruit the Plum takes a high position, and beginning with Rivers' Early Prolific, and ending with the west-country sort called Wyedale, the season is prolonged from July to November, and by adding the latest Bullaces, and beginning with the Myrobellas, or Cherry-Plums, it will be no exaggeration to say we have fresh Plums for half the year.

When the drying process is better understood and practised we shall hear no more complaints of glutted markets, and good fruit being allowed to rot on the tree, because it does not pay to gather it. Alas! I have seen lanes in East Kent strewn with good Plums blown from the trees which overhung the hedges, but as this was previous to the starting of country jam factories, I hope such is not the case now. French Plums and Prunes are two qualities of dried fruit, produced in large quantities in Alsace, in the Rhine Valley, and also in Servia, along both banks of the Danube. But we are getting finer fruit lately from California; and I do not despair of home produce in time coming to the front, if only the fruit-farmer will grow the proper varieties, and adopt the most approved methods of curing.

Plums may be grown as standards, or as natural bushes, and do not require the amount of pruning and attention that other fruits demand, as they naturally form fruiting spurs along the main branches which only require to be slightly thinned, and any crossing shoots removed, to render the tree abundantly fertile. Some varieties, as Denyer's Victoria, are so prolific, that the branches often break with their weight of fruit, and such should, therefore, be grown as bushes or pyramids; while others, as the Washington, Magnum Bonum, &c., form stiff, upright trees. Damsons should be planted round the orchard or plantation as a shelter from the wind, and may even be placed in the hedges, where they will make lucrative screens.

As a rule, those Plums which permit the stone to be cleanly removed are the best, the "clingstone" section being mostly fit only for culinary use or jam-making; but the fence which divides these is rapidly being removed by hybridists, and we now have Plums of high quality, that are not perfect free-stones, but why this difference is so patent a fact I should much like to know.

I will divide Plums into simply—I., Dessert; and II., Culinary varieties; but I must here interpolate the note that some sorts which, grown in the open, are merely fit for cooking, are often very good from orchard-house trees, or from S.W. and W. walls, especially if left on the trees till they begin to shrivel; examples, Coe's Golden Drop, Prince Englebert, and Mitchelson's, and, best of all, Blue Imperatrice. *Experience.*

(To be continued.)

Market Gardening in the Midlands.

For a century or more market gardening has been a distinctive feature of the rural industry of East Bedfordshire. There the lower greensand and the Oxford clay meet, and the alluvial lands formed by the river Ivel—a tributary of the great Ouse—are largely composed of the sand from the greensand hills and of the Oxford clay, the resulting soil being well adapted to the requirements of the market-gardener. About the middle of the century several circumstances combined to give a fresh impetus to the market-gardening industry in this district. Not only was the demand for such produce rapidly increasing, but the farmers were still restricted to a certain limited rotation of crops by the covenants of their leases, and were consequently prevented from catering for the vegetable markets, even if they had wished to do so. In the forties the Great Northern Railway Company ran their main line through East Bedfordshire, and thus opened up to that district the London market and the northern markets. Later, the London & North-Western Company ran their branch line from Bletchley to Cambridge, intersecting the Great Northern at Sandy, and thereby opened up to the same district the markets west and east. In these favourable circumstances the industry flourished and extended, and there were soon thousands of acres under market-gardening cultivation in this part of the country.

This industry has been affected by the agricultural depression in several ways, but chiefly by calling forth a competition with the market-gardeners on the part of the farmers. The latter, who had previously looked down rather superciliously upon the industry that had been carried on mostly by holders of only a few acres, were now glad to turn to any new crop or new system of culture that would help them in their difficulties. Landlords were compelled to cancel their restrictive covenants, and to allow their tenants to grow what crops they pleased. The result is, that many a farmer now gives a considerable number of acres to the production of what was once practically the monopoly of the market-gardener. Moreover, market-gardening proper was taken up in many parts of the country which the railways had opened up to the great markets. Then came the still increasing competition of the foreigner, due largely to the same causes—the universal agricultural depression, and the increased facility of carriage.

But the market-gardening industry of East Bedfordshire has continued to flourish and to increase, in spite of both home and foreign competition. Those engaged in it are men of energy and resource. Untrammelled by the agricultural traditions of the farmer, they have known how to move with the times, and to adapt themselves to the requirements of new circumstances. They have met competition by constantly improving their methods, by introducing new crops, by anticipating or even creating new demands, by unstinted manuring of their lands, and by pushing their productions into all accessible markets, both home and foreign. They have retaliated upon the foreigner by sending their productions to the Continent; and fresh green produce has even been sent from Bedfordshire to America. So rapidly do their methods change, that fathers of middle age find themselves obliged to accept innovations forced upon them by their sons. Were our farmers to take a lesson from these market gardeners, we should hear much less than we do of the ruin of agriculture.

Just now these market gardeners have a fiscal grievance of which the public will hear more than it has yet heard; and the public, in their turn, are beginning to fear that the heavy manuring of large tracts of land, to which the market gardeners are compelled to resort in order to maintain a high degree of fertility in their land, will become a source of danger to health.

The fiscal grievance is this. Many successful market gardeners are liable to the income-tax. They pay a high rent—on the best lands from £4 to £6 an acre; while the farmer's rent is low, often averaging not more than £1 an acre. The farmer pays income-tax upon only one-third of his rental, the market gardener upon the whole of his. At the same time, now that the farmer is free to grow what he pleases, he, with his low rental and his low income-tax, can, and often does, compete with the market gardener by growing the same stuff. The market gardener very naturally asks why he should pay three times as much income-tax as the farmer upon land which both crop in the same way? Practically, when the farmer's rent is £1 per acre and the market-gardener's £4, the latter pays twelve times as much income-tax as the former; but, of course, this does not touch the principle in question, though it makes the grievance all the sorer. Market-gardeners who appeal to the local commissioners are told that they are not "farmers," though they may hold as much land as some of those who are classed as "farmers," and they get nothing by pleading that the legal terminology that differentiates "market-gardener" from "farmer" is now obsolete. At least one case has occurred in this district in which the market-gardener has refused to pay, and has suffered distress to be levied upon his goods.

The other difficulty referred to above is one which does not admit of so easy a remedy. With high rents and very heavy labour bills—some of the crops requiring almost constant attention, the market-gardener is compelled to crop his land as often as possible, and to make each crop as abundant as possible. In order to do this, he must use enormous quantities of manure, both natural and artificial. Much of the land receives every year, or nearly every year, from thirty to forty, or fifty, or even seventy tons of manure, mostly of farmyard or stable manure. Hence the tilth-soil is nearly always heavily charged with putrescent matter, or matter imperfectly decayed, and not only malodorous, but likely to be foul with dangerous germ-life. And this state of things extends for miles and miles, and also immediately surrounds the villages. The moisture drains through the earth into the springs, and contaminates the wells. Moreover, the demand for constant supplies of manure appears to necessitate the constant presence on the railway-sidings of lines of trucks filled with stinking and rotting stable and other refuse. This condition of things is now attracting serious attention, and offers a problem very difficult of solution. The sooner the problem is vigorously attacked the better. That it is insoluble no one need fear; nor that the market-gardeners will fail to attack it in the most resolute and intelligent way. The public affected by it is themselves, and the small towns and villages that mainly depend upon the market-gardening industry. The men who have shown themselves able to meet the world's competition successfully, are not likely to be beaten by a difficulty at their own doors. *A. Ransom.*

FORESTRY.

THE HOME NURSERY.

(Continued from p. 104.)

Management.—What, then, are the conditions essential for ensuring well-ripened wood? Probably the weather is the most important factor in this connection, and we know that a hot, dry autumn is the best ripener of seed and wood that we can have. But the weather is, unfortunately, not under our control, and it is not, perhaps, at all times possible to get exactly what we aim at without it. But we can exercise a very considerable control over another important factor in plant growth, viz., soil, and it is with this that anything that can be done by artificial means must be carried out. Agricultural chemists roughly divide manures into three classes—nitrogenous, phosphatic, and potassic, and their effect upon plant life generally is pretty well known. Nitrogenous manures stimulate growth, while the mineral manures favour seed production and the elaboration of those substances in the plant which enter so largely into seed—carbo-hydrates. In the use of nursery stuff these products of assimilation are not needed for seed production or rather flower-buds, and are available for stem and leaf growth, and if we can by any means favour their formation and accumulation, we ensure in a great measure the following year's growth. It is evident, therefore, that stimulating manures, or those which contain large quantities of available nitrogen, are less likely to produce hard, well-ripened wood than those in which mineral matter, such as potash and phosphates, predominate; and the former of these (potash) is an important factor in the production of starch. In heavy soils, potash is usually plentiful enough; but in light ground, its application in the form of kainit, wood-ashes, &c., proves highly beneficial. Whatever nitrogen is applied to nursery crops should either be in the form of farmyard manure applied to a previous farm or garden crop, such as Potatos or roots, or in the form of a green-crop dug in. Well-rotted vegetable-mould also makes a good dressing in soils deficient in humus, but if the ground can be spared, nothing is better than farmyard manure, applying it to an annual crop before the nursery stock is put in. In some soils, slaked lime or chalk also acts well, and good loam can never do harm. In short, slow-acting manures of any kind are more likely to produce stout, healthy plants, than forcing manures, which induce a quick and sappy growth. It is a great mistake, however, to go to the opposite extreme, and keep nursery ground in poor condition, for half-starved plants are never favourable subjects for transplanting.

Stoutness rather than length should be the aim of the grower, and this is best assured by regulating the supply of soluble plant-food in the manner indicated. Dry, sandy soils are more easily managed in this respect than heavy ones, and the former should always be chosen for most nursery crops in preference to the latter. Judicious manuring, clean ground, and plenty of room between the plants, will usually mean properly-grown and rooted nursery crops, providing we limit ourselves to those species which have a reasonable chance of success in the soil and situation. *A. C. Forbes.*

DECIDUOUS CALANTHES.

Those species and varieties of Calanthe which are deciduous, viz., C. Veitchi, C. V. splendens, C. V. alba, C. Victoria Regina, C. burfordiensis, C. bella, C. Sedeni, C. Sandhurstiana, C. Harrisii, C. revertens, C. nivea, C. Bryan, C. labrosior, C. luteo-oculata, C. rubro-oculata, and C. aurantiaca are among the most useful flowering stove-plants in cultivation, their arching racemes of flowers making them very effective when contrasted and arranged with Palms, Ferns, and foliage plants. Generally where many varieties are cultivated, a succession of flowers may be kept up during the period from November to April, and the flower-spikes, when severed from the plants, last for several weeks when placed in water and kept in a cool apartment.

The plants require annual repotting, but the exact date for the operation is difficult to determine, although the most suitable time is when the new growths are a few inches high, there then being no danger of the young roots being injured. My practice is to turn the plants out of the pots and shake them out of the old soil, cutting off the dead roots to about 1 inch in length, the stumps of these helping to keep the pseudo-bulbs steady in the soil till fresh roots emerging seize upon it. Previous to re-potting, the base of each pseudo-bulb should be carefully examined for scale insects, which if not removed at this period may cause endless trouble all through the growing season. They may be easily eradicated now with a stiff brush, and suds made of soft-soap. Where the space in the glass-houses is limited, or where a great quantity of cut bloom is required from a small space, I would recommend putting four or five of the strongest pseudo-bulbs into 6-inch pots, and the same number of smaller bulbs in 5-inch ones. Many cultivators pot Calanthes singly, a plan which has its advantages, as during the growing season the bulb can, when necessary, be treated separately, and when in bloom nicer arrangements are possible. The flower-pots made use of should be either new or clean old ones, and they should be half-filled with clean crocks, with some sphagnum moss placed on top, or in place of this a layer of very fibrous soil—an important point, as Calanthes require much water during active growth. The soil should be of a firm retentive nature, yet of such texture that the roots can enter it easily, or it will become sour in a short space of time. Good turfy loam answers the purpose best, and may be used in the proportion of three parts, the remaining part consisting of well decayed Oak-leaves, coarse silver sand, and some finely-chopped sphagnum-moss, the whole being well incorporated. Some gardeners mix decayed cow-dung in a dry state with these ingredients, but it often induces the growth of a kind of white fungus, injurious to the plants. For this reason weak liquid-manure is to be preferred when the plants are well established and in need of assistance. In potting the plants, the soil should be shaken down till it is moderately firm, and brought to within an inch of the rim; the plant being then placed on the surface and more soil added, pressing this with the hand firmly on to the old roots, burying the base of the plant ½ inch, and making the surface level.

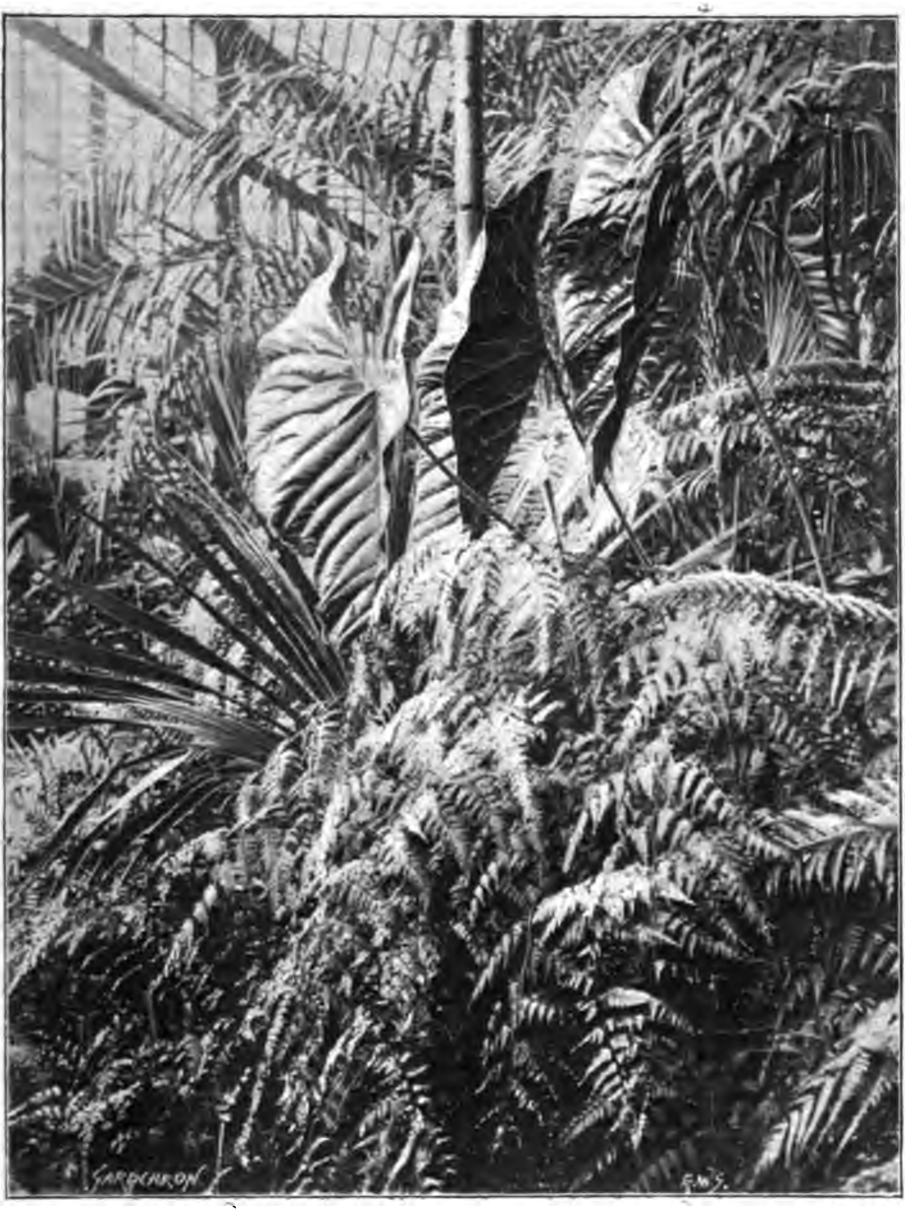

Fig. 91.—A view in the Palm-house, Botanical Gardens, Glasnevin. (See p. 241.)

After potting the plants, place them in what Orchid-growers term the best and lightest position in the East-Indian house, although Calanthes may also be grown to perfection in Pine-stoves and Cucumber-houses. Let no water be afforded to the soil for several weeks, which is a point of practice that inexperienced gardeners should pay attention to, because a wet soil at that stage will cause the tips of the young breaks to turn back, impairing the health of the plant, and showing its ill effects the whole of the season of growth. My practice is to keep the plants dry, and only to damp between the pots twice daily till growth has advanced, and then to lightly sprinkle the soil occasionally with a fine rose watering-can. Under this sort of treatment the roots soon approach and seize upon the side of the pot, by which time growth has made considerable progress, and water may be gradually increased in quantity. When the plants are quite established, some roots appear on the surface of the soil, calling for a layer of fresh turfy-loam to be placed lightly over them. This additional soil promotes healthy growth. During active growth the Calanthe should be afforded abundant aerial moisture, much heat and light, but no strong direct sunlight, this last being permitted only when the new bulbs begin to form, and then only in a very gradual manner, so as in time to inure the plant to sunshine, which may amount to full exposure by the time that the pseudo-bulbs are full grown. Towards the end of the autumn, when the foliage acquires a yellow tint, the amount of water must be gradually diminished, until the season of flowering is over.

Deciduous Calanthes may readily be propagated by removing the old back pseudo-bulbs, and inserting them in flower-pots filled with sphagnum-moss, standing them, preferably, on a shelf near the glass, and lightly sprinkling the sphagnum-moss when it has got dry. The pseudo-bulbs will soon begin to make growth, and they may then be re-potted as previously advised. The varieties that flower later in the year than those previously named, such as C. Regnieri, C. Stevensii, C. Sanderiana, C. Williamsii, and C. gigas, greatly prolong the season of Calanthes, and for that reason if for no other they deserve general recognition.

Calanthes, when at rest, should not be placed in a low temperature, but rather stood close together on a shelf in one of the warmest houses, and be kept quite dry at the root. Calanthes thus treated will start anew in the spring season with increased vigour.

Seedlings raised from sowings made last year may now be potted off, placing them to the number of five or six around the rims of very small pots, which should be hung up near the roof of a warm, moist house, and be afforded the same kind of treatment as that advised for the mature plants. If any Calanthe-plant is bearing seed-capsules, let it stand in a sunny position; and when the seed-capsules begin to take on a brown tint a piece of tissue-paper should be tied loosely around each, in order to prevent the loss of the seeds. By the time that the seed is ripe many of the plants that are now being re-potted will have made a considerable number of roots, and the seed may be sown on the pots that contain the best-rooted plants. Until it germinates, the soil should not be afforded much water, but should be merely kept moist by an occasional sprinkle. Under favourable circumstances the seed will have germinated in about three months, but the seedlings must not be disturbed before the spring following. *W. H. White, Burford, Dorking.*

NURSERY NOTES.

MESSRS. W. BALCHIN & SONS, HASSOCKS' NURSERIES.

The Hassocks' Nurseries always afford interest and instruction to the visitor, especially in the spring months, for the houses contain a very varied collection of plants, many of them hardwooded. If one would see the beautiful blue-flowered Leschenaultia biloba major, he should go to Hassocks at that time of the year. We have seen recently, at the Royal Horticultural Society's meeting, some of the splendid examples of Boronia heterophylla produced there. Plants not seen in any other nursery are grown here with great success. Amongst them, besides those named above, are Tetratheca ericoides, or more properly, T. pilosa, can be seen in good-sized densely flowered specimens, literally wreathed with its festoons of charming mauve-purple blossoms. Time was when this plant was grown into large sizes for exhibition purposes, but is now rarely or never met with at a flower show. The blossoms have the additional attraction of fragrance. There could be seen many small plants of this striking Australian shrub, for it is in demand, and there are plenty of small two-year-old plants of Boronia heterophylla, in company with finer examples of an additional two years' culture. What strikes the visitor about all the specimens, and especially the small ones, is the size and brilliancy of their blossoms.

Two distinct types of Boronia megastigma can be seen here, the one a form that was brought out a few years ago, is of a tall, distinctly erect, stiff growth, like the common Broom; the other the delightful semi-pendent elegant form we sometimes see exhibited from this nursery. It is this type which is so largely propagated, a light coloured, or what, without much stretch of the imagination, might be termed a white form of this fragrant plant is probable, for as many as three small specimens have each produced a shoot bearing blossoms of this colour, and it is intended to propagate them. Small plants of this species, one year from cuttings, were laden with blossoms.

B. serrulata is found there in large examples; also many small ones. This appears to be capable of propagation at Hassocks with as much ease as any soft-wooded plant. Some quarter specimens of Erica Spenceri, the flowers deep rosy-pink, afforded charming patches of colour; and E. perspicua nana, soft pink, a vigorous grower, dwarf and free; a specimen of the pretty E. propendens, which came to the fore at a recent meeting of the Royal Horticultural Society, though by no means new, was also in fine bloom, and no doubt destined to find a congenial home in these nurseries where the greenhouse Heaths do so well.

A fine specimen of Darwinia macrostegia (tulipifera) grandly grown and flowered, affords another illustration of the hard-wooded plants cultivated here, and now there are no large exhibitions in or near London in May and June, the "Tulip-bearing Myrtle" is not seen in such form as it once was. What is cultivated here as Acacia cordata is an erect close-growing subject, carrying in great plenty long vertical spikes of pale yellow flowers; one specimen with almost countless flower-stems was fully 4 feet high and as many as 3 feet through.

A very large stock of the finely variegated hybrid Campanula Balchini, illustrates what a most valuable subject it is for decoration. It was raised from C. isophylla alba × C. fragilis; every leaf is broadly margined with white; it is most valuable for forming an edging to a plant stage. Grown in a gentle warmth at this season of the year, and in full exposure to the light, a brilliant reddish tint pervades the points of the shoots, and adds greatly to its decorative value. Partaking of the character of growth of C. isophylla alba, it will presently become covered with blue flowers, and is thus an excellent companion. As a basket plant, it would be difficult to name one superior to it. Streptosolon Jamesoni was remarked in fine bloom. There must be something in the atmosphere of Hassocks which imparts such a rich reddish-orange colouring to the flowers of this plant.

There is a large batch of seedling forms of Richardia Elliottiana, but so far they do not afford indications of any departure from the type. Some fine forms of Hippeastrum were in bloom, large, and of handsome shape; and a batch of seedling Diplacus glutinosus, from which much is expected, has yet to flower. There is a large batch of Humea elegans, which is always in brisk demand. Other plants in flower were Azaleas, viz., Bernard Andre alba, a very fine white; Cocardeau Orange, rich crimson-salmon; Empress of India, rosy-salmon, a charming variety; Madame K. de Wissen, a very fine white, &c., all profuse of bloom.

Of decorative plants, there were Lilium Harrisii, Freesias, Astilbe, Richardia in variety, Hydrangeas, especially the variety Thomas Hogg, &c. *R. D.*

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

The Chrysanthemum.—The plants earliest struck and now standing in 48's, being sufficiently well-rooted may be shifted into 32's. The strongest plants should be taken first, but if on being turned out of their pots any are found to be insufficiently rooted, such should be returned to their pots for repotting in a week or ten days. The compost for this potting may consist of three parts turfy loam, one part flaky leaf-soil, and one part rotten manure from a spent hot-bed or Mushroom-bed, together with as much coarse sand as will keep it open. The soil should be made moderately firm in potting the plants, and the latter put into cold frames, keeping them rather close for a few days, and then removing the lights in the daytime. The potting-soil being in a properly moist condition, the plants will scarcely require any water for six days. Before the tops of the plants reach the glass, the frame should be raised by placing a brick or two under each corner. Plants struck late should be potted in 48's when nicely rooted, and placed in a cold frame.

Violets.—The propagation of Violets for winter-flowering should now be undertaken. For this purpose, the strong side-growths or short-stemmed runners that are found upon plants which have been grown in frames should be pulled off and planted in a not too sunny or dry place, at a distance of about a foot apart. If there is a doubt about the soil being sufficiently good, some short rotten manure should be forked in before setting out the runners. A mulch should be afforded the plants in dry weather, and water when necessary. What runners appear should be removed early. A sprinkling over-head in the evenings with a water-pot or the syringe will be beneficial in dry weather in keeping the plants healthy, and checking the attacks of red-spider. The syringe with an elbow-nozzle is the best implement, as by it the water can be directed under the foliage, where spider most do congregate.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury Gloucester.

The Alpine Garden.—If a garden, or part of a garden, for the display of alpines is properly formed and suitably planted, it usually forms an interesting and charming spot. It is best when it is partially or wholly masked from view, the small rocks usually employed in making it being better adapted to the cultural needs of the plants than to produce effect. So small and dwarf in growth are some of these plants, and many of them gems, that it is advisable to grow them as single plants than to plant in masses. In forming an alpine garden, a position fully exposed to sunlight, and as much raised above the surrounding level as possible, should be chosen. It is also important that no trees or big shrubs should be near it, as the roots of these would impoverish the soil. The form of the rockery may take the form of high ridges intercepted with paths, and these ridges may be planted on either side, varying aspects being chosen to suit the various species of plants. Thorough drainage is essential, and a soil varying in depth from 2 to 3 feet. In this body of soil they root deeply, and once established no drought has any effect on them. Any kind of stone, excepting shale or ironstone, about 2 to 3 inches in thickness, and that is capable of withstanding frost, may be used to form the pockets, as the receptacles for holding plants are called. These stones should be buried edgeways to part of their depth. It is necessary to successful culture that the soil afforded each plant should be suited to its needs, some need lime in some form, some sand, fine gravel, broken slate, and some thrive with the least modicum of soil, and seem to subsist on the moisture present on the surface of fissures in rocks, as in the case of Phyteuma. Some of the species will thrive in any porous loam mixed with decayed Oak-leaves, sand and sharp grit. Many of the tender plants withstand hard frost if kept dry, which can be done by placing a sheet of glass on the edges of the rock, thus covering the plant, whilst admitting light and air. All succulent plants, especially the Sempervivums, of which there are a number of beautiful and distinct varieties, should have the soil made very porous by mixing limestone or soft red brick, broken small, with it. Many of the mossy Saxifrages form lovely cushions of greenery, and those which form rosettes throw up lovely pyramidal panicles of flowers. The alpine varieties of Phlox amœna, P. procumbens, and P. setacea, Aubrietias, Veronicas, and Androsaces, which trail and hang over the stones of a rockery, make showy masses when in flower. The species of Sedum, Hepatica, Lithospermum, Dryas, Erodium, Globularia, Iberis, Gentiana, Erinus, Drabas, Dianthus, Papaver, Soldanella, Ajuga, Lychnis, Linaria, Iris, Funkia, Campanulas, Anemones, Acænas, make excellent plants for an English alpine garden. Species of Crocus, Cyclamen, and other small-blooming bulbous and tuberous plants give an interesting display of forms and flowers during a greater portion of the year. Many of the coarser alpines are more suitable for, and thrive better in the borders of herbaceous plants. Most alpines may be removed and divided or planted at the present season. Those which cannot be divided must be increased by means of seed or cuttings.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore Maidenhead.

Hoeing Fruit Quarters.—When the surface is sufficiently dry it is well to hoe the ground in order to check the growth of small weeds, which are germinating fast after the recent rains. Where the ground about the trees and bushes is not mulched, this hoeing will act in a two-fold manner by keeping moisture in the soil as well as by killing weeds. A small quantity of freshly-slaked lime scattered about under the fruit-bushes at this season is beneficial, and will to some extent assist in keeping the attacks of insect pests in check.

Mulching Raspberry-beds.—The roots of the Raspberry coming to the surface of the soil in considerable numbers, are apt to suffer in medium and light soils in times of drought, at least that is the case in the warmer parts of the country, unless mulched with decayed manure while the ground is still moist. Liquid manure from stable-tanks, &c., may also be poured on the land with advantage at this season. Red and Black Currant-bushes may be similarly treated.

Birds and the Fruit-buds.—The harm done to the fruit-crops by tom-tits and bulfinches is becoming worse every year, the recent mild winters having doubtless increased the numbers of birds. The Preservation Act passed by Parliament has likewise helped in this direction. In the Taplow district the buds of Pear, Cherry, and Gooseberry have already suffered badly; some trees of the first-named were quite denuded of their flower-buds when these were in a somewhat advanced stage. I have noticed that this spring the sparrows have been more than usually destructive to Pears and Gooseberries especially, while the small tits and bulfinches have been as great depredators as ever. Applications of Quassia-liquid, petroleum-emulsions, or of lime-wash have had only a partial effect, and after a few days they seemed to lose their deterrent power.

Terminal blossom-buds.—Owing probably to the hot weather experienced last summer and autumn, fruit-buds developed in a more than usual degree on the young wood of the same season's growth, in many instances Pears and Apples being freely studded with fruit-buds where wood-buds are usually formed. This applies chiefly to Pears on wall-trees and bushes, and to Apples. The extension of the growth is thus likely to be checked if the flower-buds at the ends of the principal shoots are allowed to remain. It will be advisable, therefore, to examine the shoots forthwith, and remove these flower-buds. This is more than usually necessary in the case of young trees of the Pear on walls.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

"Mossing" the Plants of Phalænopsis.—The species of Phalænopsis which flower in the winter having begun to make roots, the stale sphagnum-moss may be replaced with new, any delay in doing this being injurious; indeed, it is advisable to perform this operation on the whole of the species. Baskets which are in sound condition will need nothing further than to have the sphagnum-moss picked out, dead roots removed, and to receive a new coating of living sphagnum-moss; whereas, decayed baskets should be treated in the following manner: first, remove the whole of the sphagnum-moss and crocks, then immerse the basket in water for the space of two hours, then proceed to remove the bars by first taking out the corner pins, and with a thin-bladed knife liberate the roots, an operation made easy by the immersion. In order to place the plant in a new basket, the better method is to remove one or two of the bottom bars, and draw the leaves upward through the basket to the required height, and replace the bars; then insert a sufficient number of crocks, to do away

with the need of a large body of sphagnum-moss. Of late years, I have made use of the pot-shaped baskets, and find that owing probably to the increased rooting-space these afford, the plants have outstripped others placed in the ordinary square baskets. In order to plant a Phalænopsis in one of the pot-shaped receptacles, it is necessary to undo the encircling wires, so that the roots be not injured by introducing them between the bars. It facilitates the removal of the stale materials about the roots if water be withheld for a few days previously; and that which cannot be picked out with a sharp-pointed stick, may be dislodged with water and the syringe. For a considerable period of time the disturbed plants should be sparingly afforded water by means of a fine rose-can, dipping being unsuitable before the roots have permeated the moss. The temperature of the house should now be increased to 75° by day and 68° as a minimum by night, and all available spaces damped once a day, the atmosphere being kept sweet by judicious ventilation. When sunlight is bright, some amount of shading is necessary. When the weather seems likely to be clear, the baskets and the undersides of the leaves should be gently sprayed with tepid rain water, which will obviate the necessity of affording frequent application of water. Phalænopsis Esmeralda should have the lightest, and P. speciosa, Luddemanniana violacea, and other kindred species, the most shaded portion of the house.

Dendrobium Wardianum and D. crassinode were grown last year in these gardens in the Cattleya-house, and the plants did better than when in former years they had been grown in the East Indian-house. The plants are now in a forward state with roots only just about to appear, that is, at that stage when it is the safest to replace the old material with the new. The most suitable compost consists of good fibrous Orchid-peat and sphagnum-moss. When the job is finished afford a copious application of water, and hang them where the syringe may be used amongst them in hot weather, and the shade is not very dense.

Dendrobium Victoria Regina.—The blue-flowered Dendrobium and the pretty hybrid D. × Cassiope are most at home in the Cattleya-house, hung up on the shady side. Neither requires a long rest-period, and less water should be afforded during the winter.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

Tomatos.—The forwardest batch of plants raised from an autumn sowing, are ripening their fruits, and will with fair treatment continue the supply until the fruits are fit for use on the new-year sown plants. Water must be afforded with care, particularly in bright sunny weather, for if the soil be allowed to get unduly dry, and is then afforded water freely, many of the forwarder fruits may crack, and be spoiled. It is far safer to maintain the soil in an uniformly moist state than to alternate from wet to very dry. Fruits that are fit should be gathered on alternate days and placed in the fruit-room till sent to the kitchen. All useable fruit should be plucked before it has become dead ripe. If the white Tomato-fly attack them, paint the hotwater-pipes with flowers-of-sulphur in lime-wash, which is a first-rate remedy, if they are heated sufficiently to give off an appreciable amount of sulphurous vapour. If Cucumbers occupy a portion of the house, however, I would not advise the use of sulphur, as it affects foliage badly sometimes. If the Tomato crop is heavy, apply manure, and top-dress with fresh soil in small quantities. Suppress all superfluous and lateral growth so as to divert the sap to the fruits. Spring-sown plants, if growing and fruiting freely, will need plenty of moisture at the root, and to be neatly tied to stakes or to the trellis. From four to five trusses per plant will be sufficient for a crop on single-stemmed plants, the leader being stopped as soon as the latest truss of flowers is visible. A stimulus either in the liquid state or as a powder may be applied, following the rule of little and often rather than in strong doses. Over-vigorous plants must be afforded only clear water, but this fails sometimes on account of a large border, or excess of manure or leaf-mould in the soil. The best kind of soil is a turfy loam, with only a small proportion of charred soil. This will usually grow Tomatos successfully under any condition, manure being applied only when the roots have occupied the whole of the soil. As a rule, the Tomato in private gardens does not obtain so much attention as other fruits, nor are the conveniences for growing the plants all that they should be, and seldom is a house set apart for growing and fruiting them. They do best when planted in a border, or if grown in pots these should be stood on coal-ashes or other material into which the roots may penetrate. For supplying a late crop, a sowing may now be made, if a suitable position can be set apart for them in the autumn. During the summer months plants may be fruited in the open air, grouping them in 12-inch flower-pots, and placing these on planks in the front of a south wall. No plant put out of doors in pots should be allowed to root into the soil, as when removing to the glasshouses a great check is inflicted. If the seeds are sown in boxes, and they are thinly scattered, the plants may be potted singly, with good bulbs of soil attached to each. Such plants grow more sturdily, fruit earlier, and give much less trouble than those which stand thickly in the seed-pan, and require careful handling and shading for some days after their roots have been so disturbed. The Mustard-and-Cress fashion of sowing Tomato-seed cannot be too severely condemned, resulting as it does in great loss of time, much labour, and poor results. The practice of starving Tomato-plants with a view of bringing them into early bearing is a mistake. At this season it is a waste of time to shift Tomato-plants periodically, and once well established in 60's, they may be shifted directly into their fruiting-pots, making the soil very firm. Growth will then be sturdy, and the crop a good one. Do not crowd the plants, as it tends to late fruiting.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Spent Crops.—No time should be lost in clearing the land of the stumps of Brussel Sprouts, Broccoli, and of all exhausted crops, as to leave them would impoverish the soil needlessly. As a rule Celery may follow these, and early Potatos. If the latter, dig the land of a good depth, breaking up the soil as finely as possible so as to prevent the tubers being ill-shapen, and dig in plenty of well-decayed manure if the land is in need of enrichment. The trenches for Celery should be dug out not too deeply, and the top spit put at the bottom, and covered with a layer of rotten manure. The distance between the Celery-trenches should be from 5 to 7 feet, 5 for early crops and single lines, and wider for double lines and later crops. The ridges may be cropped with French Beans, Lettuces, Spinach, and Turnips, or any vegetable or salad plant that matures rapidly. Any Celery still in the trenches should be dug up and laid-in on a north border, the ridges levelled, and the land made firm, in readiness for being sown with Peas or Runner Beans, &c.

Carrots.—In the colder parts of the country and on heavy, adhesive soils, the main crop of Carrots should be sown without further delay, or as soon as it is in a suitable condition for sowing. Before anything else is done, the drills should be sprinkled with fresh soot and wood-ashes, useful in warding off attacks of the maggot. Carrot-seed sown early on a warm border having now germinated, the Dutch-hoe should be passed between the rows, and if weeds are appearing these should be drawn out by hand and taken away.

Broccoli. — Make sowings of the main crop varieties, and in a fortnight a second sowing, Knight's Protecting, the Ledsham (one of the latest), Goshen (also late), Model, and Methven June are very trustworthy varieties. Let the seed be put into shallow drills drawn at 9 to 10 inches apart, and if convenient let the seed be well in the open, so that the plants may grow sturdily and short legged, a very important matter. The soil of the seed-bed should be made firm, and the seed well coated with red-lead, first damping it with a little milk or linseed oil. Keep a sharp watch on the bed, and should the slugs make havoc with the plants, dust the soil daily with soot and wood-ashes. A good kitchen gardener is always on the alert, and will require no instructions in regard to this matter by the head gardener.

Early Cauliflowers.—The plants from the spring sowings should by this time be large enough to lift with a ball, and plant on a warm border. They should be taken up and planted with a trowel with as little root disturbance as possible, loosening the surrounding soil, and fastening the root mass firmly. Cauliflowers differ from Broccoli, and require a fairly light rich soil. The plants wintered under handlights should now have almost complete exposure, the tops being put on the glasses when frost is expected. It will soon be prudent to remove them altogether.

THE APIARY.

By Expert.

Methods of Dealing with Brood.—In early localities something may be done during the present month towards equalising the deposits of brood in the various combs of the brood-nest. My ideal of a stock when ready for supers is that it be filled with brood or eggs from side to side, and top to bottom, excepting at most a few days' supply of food in case of a serious reverse of weather. Bee-keepers should work up to this ideal all along, and whether the hive contains four frames or fourteen, each frame should conform to its requirements. Whatever operations are necessary during the month, care should be taken to keep the brood-nest warm, and even moist. Winter packings must not be removed till the bees require more room. Water-troughs, fitted with moss or tea-leaves, may be placed in sheltered sunny spots about the apiary, and kept regularly supplied with water, if there are not convenient drinking places close by. If, however, running watercourses are near at hand, it is a waste of labour to provide troughs, and bees will pay no attention to them.

Feeding.—Good stocks will soon be well "under weigh." Brood-rearing will be making rapid progress, and when natural pollen can be gathered, the stimulus already acquired will be continued, even without any care on the part of the bee-keeper. Honey from natural sources will, however, be scarcely obtainable in sufficient quantity for the needs of stocks for weeks to come, and attention must be given even by those who wish to do as little as possible, that the prosperous condition of breeding stocks may be continued without a check until the honey harvest opens. Artificial supplies by means of a feeder must be given in all cases where want is threatened. Those who wish to stimulate all they can, and do not grudge the trouble, will keep on uncapping a few inches of sealed stores daily in each hive, or maintain a constant though slow supply of very thin syrup through the feeder. Care must be taken that no more syrup is given than the bees require for present use, and should they be found to have got too much, the supply should at once cease, and the knife be applied frequently to the sealed combs. In using the knife do not remove the comb from the hive, nor even cut the caps from the cells. It is quite easy to force all the bees down by smoking, so as to leave the sealed portion of the comb visible, when the flat of the knife may be drawn firmly over the cells, or the surface of the capping scratched, the lids being only bruised. This avoids trouble from daubing honey about, and leaving portions of loose cappings to be used by the bees to form connections between their combs.

BOOK NOTICE.

A Text-Book of Agricultural Zoology.—By F. V. Theobald, M.A. (Blackwood & Sons).

This is a little book treating of "the life histories, the habits, the peculiarities, of all the animals which affect for good or for evil, our stock and crops, whether on the farm or in the garden, and the structure and development of domestic animals." It is clearly impossible in a little volume of 500 pages to explain the peculiarities of all the animals with which the gardener or the farmer is concerned, but it is remarkable what a large amount of information the author has been enabled to compress in his limited space. The illustrations are, generally speaking, excellent and relevant. An appendix on the prevention and destruction of insect-pests, is a valuable feature of the book, which is one which should find a place on the shelves of every agricultural student.

EDITORIAL NOTICES.

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, April 22—Royal Botanic, Meeting.

SUNDAY, April 30 { International Horticultural Exhibition at Mont St. Amand, Ghent, Belgium, continued to May 9.

SALES.

TUESDAY, April 25 { Imported and Established Orchids, at Protheroe & Morris' Rooms.

WEDNESDAY, April 26 { Clearance Sale of Orchids and Stove Plants, at The Gardens, Bisterne, Hants, by order of the Rev. Cecil Mills, by Protheroe & Morris. Japanese Lilies, Palm Seeds, Roses, Greenhouse Plants, &c., at Protheroe & Morris' Rooms.

FRIDAY, April 28 { Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period April 9 to April 15, 1899. Height above sea-level 24 feet.

Remarks.—A dull and almost sunless week, with cold winds and much rain.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—49 6°.

Actual Temperatures:—

London.—*April* 19 (12 p.m.): Max. 61°; Min. 39°.

Provinces.—*April* 19 (6 p.m.): Max. 57°, Norwich; Min. 41°, off St. Andrews.

Royal Horticultural Society.

Out of the ten or more meetings of various kinds held on Tuesday last, at and in connection with the Royal Horticultural Society, none was of more significance for the future than that presided over by Mr. Elwes. Those who are familiar with the history of horticulture in general, and of that of the Royal Horticultural Society in particular, will call to mind the services which were rendered in olden times by the collectors sent out at the cost of the Society. Specially brilliant were the services of Douglas, hardly less so those of Fortune. After a time the practice was discontinued, mainly on account of financial difficulties, but partly because the great nurserymen undertook the work for themselves. Then arose the passion for Orchids. Collectors were, and still are, sent out in numbers. So numerous and so industrious are they that it is no idle fancy to dread the extinction of some of the more valued species. But this remark applies particularly to Orchids. With few exceptions our importing nurserymen confine themselves chiefly to Orchids.

What are spoken of as "new plants" are now comparatively rarely shown. Hybrids and cross-breeds, even among Orchids, now take the most prominent part in our exhibitions, so far as novelties are concerned. The nurserymen doubtless know their own business best, and they tell us that "new plants" do not pay, and that the profit to be obtained from hardy shrubs or herbaceous plants is not sufficient to make it worth while to send out collectors.

Having some inkling of the treasures yet to come from Western China and other districts, we venture to think this reticence shows a want of enterprise. We have repeatedly called attention to the dried plants collected by Dr. Henry, the Abbé David, and others, some of which have been figured in various readily accessible botanical periodicals. But whatever be the outlook commercially, there is happily a band of cultivators who love plants for their own sakes, rather than for the money they may be worth, a band who are not swayed by fashion, but solely by the interest or beauty that a plant possesses. These gentlemen not unnaturally think that the time has come when the Royal Horticultural Society might take steps to promote the collection and distribution of interesting plants at present untouched by commercial collectors. There is no fear whatever that the sources are exhausted. The great continent of North America we may well leave to our cousins, they are not likely to overlook anything that is good; Russia will doubtless monopolise Central Asia and Manchuria; but there are, omitting purposely strictly tropical and semi-tropical districts, vast areas in China, Nepal, Tibet, Upper Burmah, Assam, parts of Asia Minor, Greece, Macedonia, and even in the Danubian provinces of Europe, from which supplies might certainly be obtained.

The Altai Mountains have been explored by Ledebour and other Russian botanists, but note what Mr. Elwes says in the *Journal of the Linnean Society* about the flora of this region, and its capability of supplying the requirements of the horticulturist, as observed in a recent visit. We take a few extracts from this paper almost at random:—

"To give an idea of the alpine flora of the South-eastern Altai, I may mention a few of the plants which were most conspicuous for their beauty near our camp on the Darkoti, or Tachety river, as Tchikatcheff spells it, thirty miles south-west of Kuch Agatch, at about 7000 feet. I have never, either in the Alps of Europe, in the Sikkim Himalaya, in Colorado, California, or anywhere else, seen such a perfect natural garden of beautiful alpine flowers as I saw here in the middle of July. Among the most conspicuous were the lovely Primula nivalis, Pall., which strongly resembles P. Parryi of Colorado; Dracocephalum grandiflorum, which grew in sheets of cœrulean blue; Polemonium pulchellum; Gentiana altaica; Pedicularis verticillata, P. foliosa, P. comosa; Allium sibiricum, or senescens, the most ornamental of its genus; Linum cœruleum; Iris Tigridia, Bunge; Pyrethrum pulchellum; a lovely blue Corydalis, growing in wet places, which Mr. Baker cannot name, and which may be new; a beautiful Aquilegia, named A. glandulosa at Kew, but much finer than that plant as we know it in our gardens; several pretty species of Astragalus, Lloydia serotina; and many well-known Arctic and high Alpine plants, such as Papaver alpinum, Draba ochroleuca, and Saxifraga oppositifolia, which were found as high up as 8500 feet, where the flora and scenery reminded one strongly of the high fjeld of Norway, and Dryas octopetala, which covered the curious dry gravelly ridges on the hill-sides in many places.

The only vegetables which we had during our stay at these altitudes were Rhubarb (R. Rhaponticum) and wild Onions; but the Tartars were also fond of the young stem of a species of Heracleum, which was too strong for my taste.

The Larch, Larix sibirica, ascended here to a little over 7000 feet. I saw young trees at this elevation about 1½ feet diameter and 7 feet high, which showed twenty-five years' growth; and a very remarkable stunted old Larch, 3 feet in diameter, and not more than 20 feet high, which must have been many hundreds of years old. Away from these there was no fuel but Willows and dry horse-dung, the common fuel of Mongolia and Tibet.

This valley is remarkable for its magnificent forests of Pine, Pinus sylvestris, which exceed anything I have ever seen before. In some places I counted as many as twenty or thirty trees to the acre, of an average girth near the ground of from 6 to 10 feet, and carrying their girth higher up than I have ever previously seen, so that at a height of 80 or 100 feet the tree would still be over a foot in diameter. The Russians, however, who, as described by a well-known German forester, are "everywhere and at all times true wasters and destroyers of forests," are making rapid inroads upon this magnificent timber, which is felled and floated down the Bija and Obb for supplying the towns and villages in the Steppe country northwards. Fire also is rapidly wasting many of the hill-sides, and when the Pine has been burnt off, its place is usually taken by Poplar and Birch."

At the meeting to which we have referred, there was an interesting discussion by Messrs. Elwes, Lynch, Dewar, Burbidge, G. Paul, Selfe Leonard, and others. The greatest difficulty seemed to be to obtain a zealous collector, competent to do the work thoroughly, and who would not flood us with rubbish—one who would work more from the love of travel and of plants than from monetary considerations only.

As to finances, the feeling of the meeting was so hopeful that no serious difficulty was apprehended on this score.

The result of the discussion at the meeting was the adoption of a resolution asking the sympathy and co-operation of the Council.

We cannot doubt that this will be given, and so we look forward with confidence to the despatch of a collector to one or other of the regions named either at once or early in the next year.

The Restio Family.

This is a group of Sedge-like perennial plants, with tall, dry, Rush-like stems, almost destitute of true leaves, and with flowers in spikelets, sometimes few in number, at other times very abundant. They are, like the Cape Heaths, almost exclusively confined to the extreme point of south-west Africa, and about an equal number is found in the corresponding part of Australia. Nevertheless, there is no species common to both countries, and there is plenty of matter for speculation as to how it has come about that these two regions, and practically none other, should be tenanted by these plants. Latterly, indeed, one species has been found in Natal, and one in the mountains of British East Africa, so that we look for further developments as the flora of these regions becomes better known. One outlier, and a very singular one, is a species which was discovered in Cochin-China by M. Godefroy Lebeuf; and another exists in Chile. With these exceptions

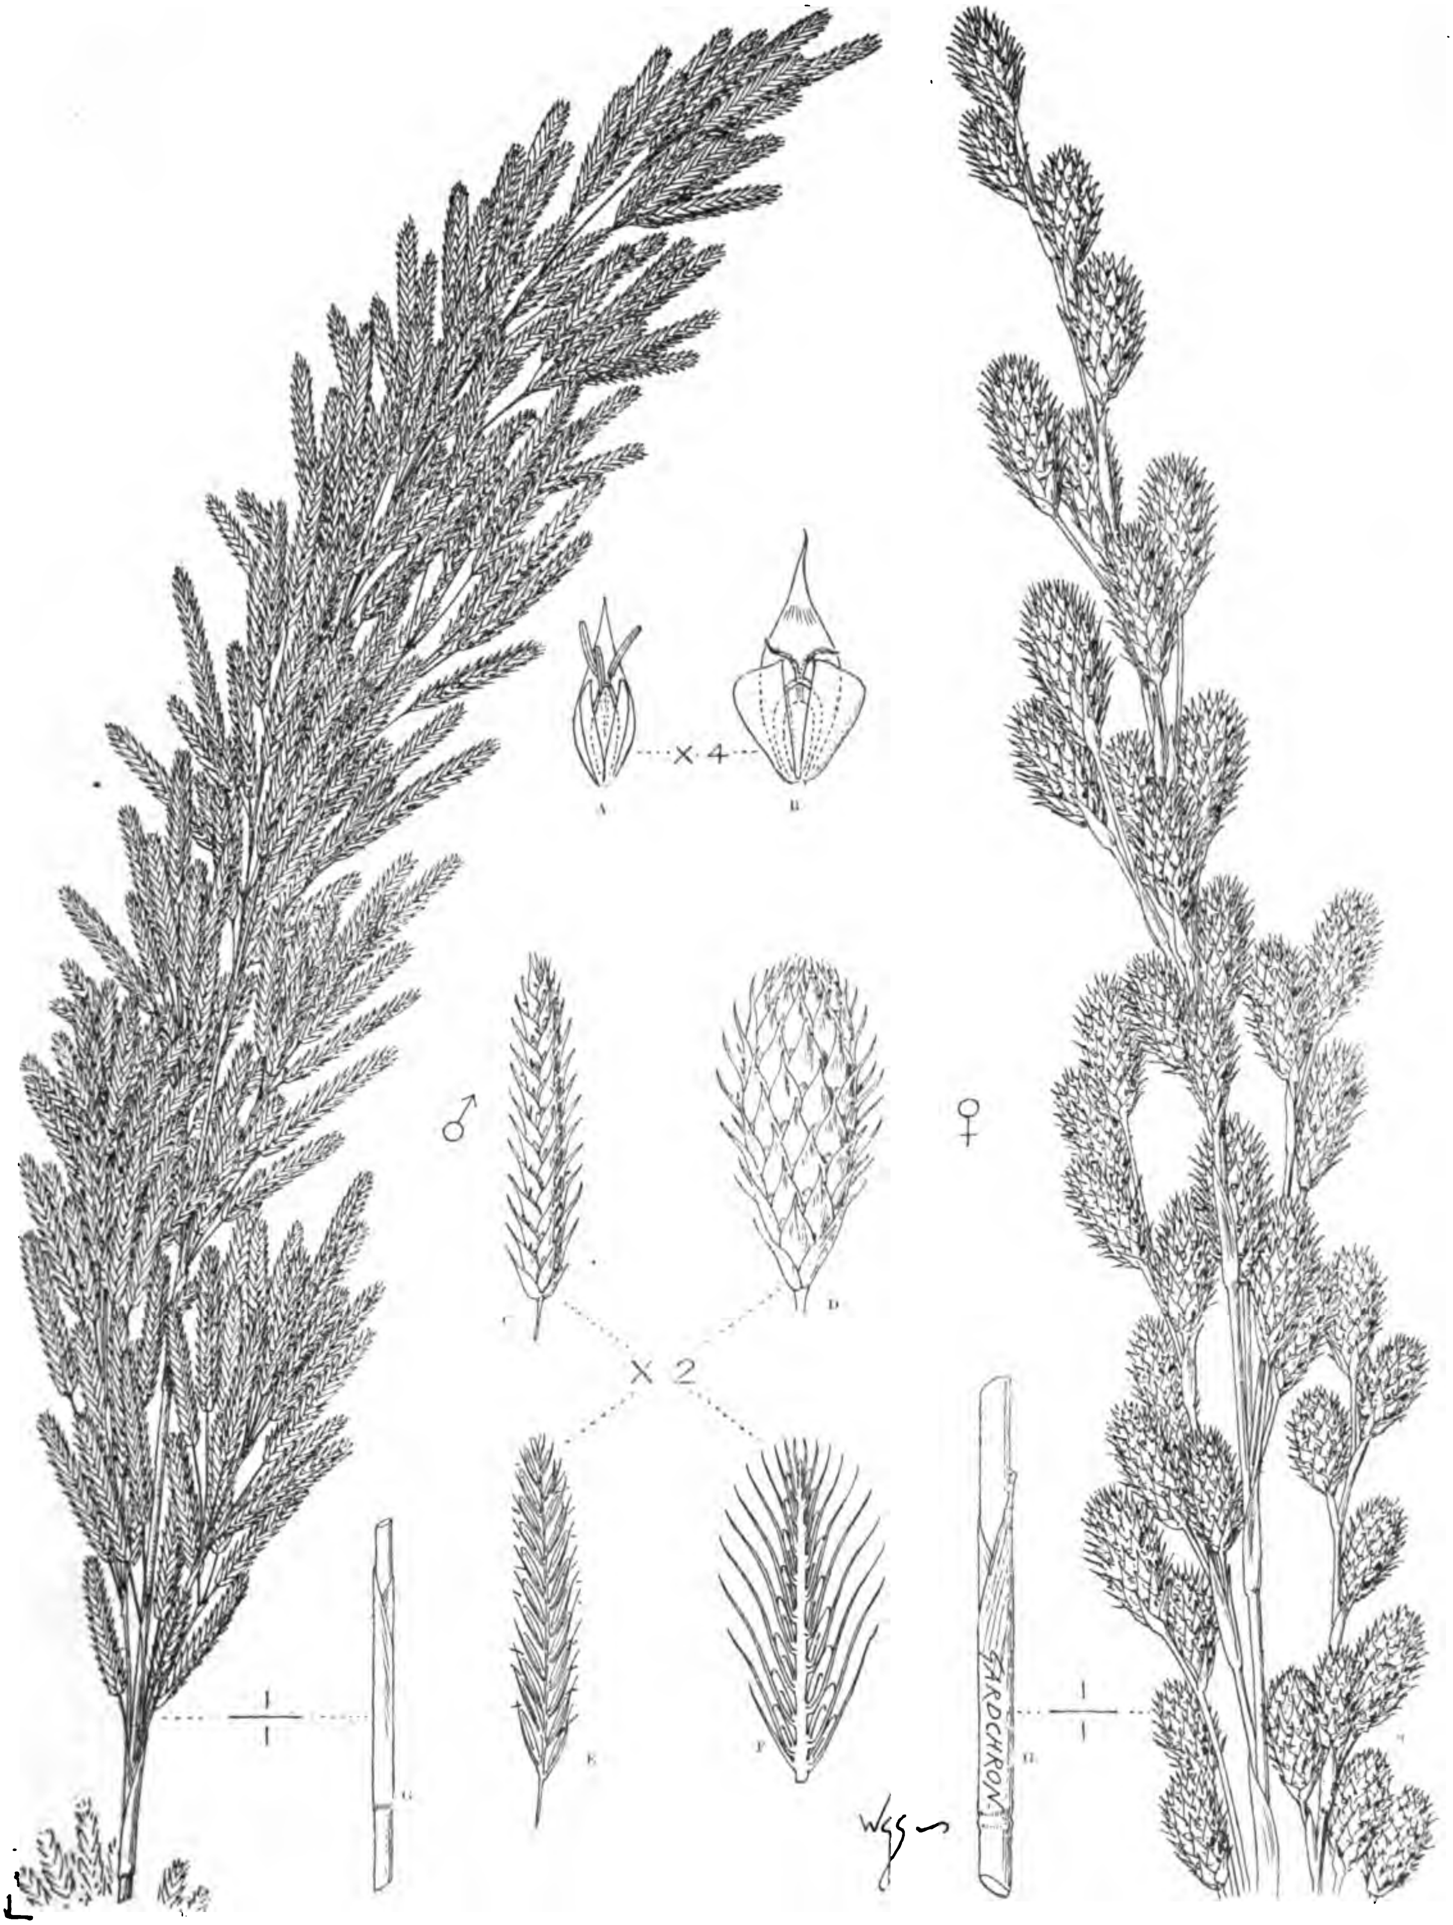

FIG. 92.—THAMNOCHORTUS SPICIGERUS: COLOUR OF THE FLOWERS CHESTNUT-BROWN. (SEE P. 250.)

A, Male flower from within; B, Female flower from within; C, Male spikelet; D, Female spikelet; E and F, Vertical sections through the spikelets; G, Sheaths and stem.

the geographical distribution is limited as above stated.

Very few of them are in cultivation. Most of them are so uninviting that even our botanic gardens contain few of the species. Till lately, indeed, we knew of but one—the plant named erroneously Willdenovia teres, but which is more correctly called Restio subverticillatus. We have known the male plant of this for many years in the botanic gardens of Oxford, Edinburgh, and Kew. Its graceful habit and pendent plumes of fine needle-like foliage render it, unlike most of its fellows, very ornamental. Whilst most of these plants are unattractive, there are some that are more ornamental even than the species just named; such are Leptocarpus paniculatus, the very numerous male spikelets of which are arranged in elegant panicles; Restio giganteus, and various species of Thamnochortus. Some of these have of late been introduced from the Cape for the purposes of house or church decoration, for which they are especially suitable. The flowers of some of these have been sown in the vain hope that they would grow—we say vain hope, for the sower has not always recognised the fact that what he has sown are the male flowers! These plants are, in fact, diœcious, the male flowers are on one plant, the female on another.

To make matters worse for the unfortunate botanist, it so happens that the male plants are sometimes very different in appearance from the female plants, and it is by no means unlikely that those responsible for the naming of these plants have occasionally mismatched them, and considered as mates plants that really do not stand in that relation to each other. And this leads us to remark that although the species are diœcious, and, as it appears, the pollen from the male must be wafted by the wind to the stigmas of the female, for there is nothing to attract insects to the flowers, yet, there is little or no evidence of hybridisation among them.

The species are sometimes very difficult of recognition, yet when once the observer gets a grasp of them he will find comparatively little evidence of variation in them, and none of hybridisation. This is, of course, a general statement, not of universal application, for some of the species show a considerable amount of variation.

It is curious to see how well these plants are adapted to the conditions in which they grow, and how every effort seems to be made to economise energy, and avoid superfluous growth, and consequent exhaustion. Their tufted or creeping habit is adapted to the sandy soil in which they grow, whilst the almost entire absence, or great reduction of the foliage, obviates excess of transpiration which in such a climate, and in such a dry soil, would speedily exhaust the plant. Male flowers are produced in abundance, but female flowers are, not always, but, usually, relatively scarce. Very often there is but one female flower to each spikelet, and it is rare for more than one seed to be perfected, so that the strain on the resources of the plant is reduced to a minimum; at the same time, the chances of the perpetuation of the species are correspondingly diminished.

The seed-vessel or fruit is capsular and dehiscent, or nut-like and indehiscent. In the former case, the solitary seed is hard and bony, but in the nut-like fruits it is the fruit that is hard and bony; whilst the covering of the seed is thin and membranous.

These facts indicate that the plants are exposed to unpropitious climatal conditions, and that their structure and conformation are correspondingly adapted to enable them to maintain themselves in the struggle.

Circumstances seem to point to the conclusion that the Restiaceæ are an old family, once more widely spread than they are now, when they seem to be doomed to extinction at, geologically speaking, a no very remote period.

Among the more ornamental species, some of which were shown at a recent meeting of the Royal Horticultural Society by Messrs. F. MILLER & Co., of Fulham Road, and which are amply worth introducing, and which could be cultivated in any ordinary greenhouse, are, in addition to those formerly named, Restio egregius, R. purpurascens, R. Rhodocoma, Dovea mucronata, a robust species growing in wet or damp places; two species of Lamprocaulos, one with shining golden-brown stems, the other with stems of a brilliant metallic-green colour; Thamnochortus spicigerus, T. argenteus, Cannomois cephalotes, and the species of Ceratocaryum. Most of these might be procured from the Cape with little difficulty; but if in the form of seed, there would be some uncertainty as to whether the seedlings might prove to be male or female, a circumstance that might lead to temporary disappointment. The two species, of which we give figures are Thamnochortus spicigerus (fig. 92, p. 249); and Thamnochortus insignis, Mast., a hitherto undescribed species of striking appearance, and a stature of 3 or 4 feet (see fig. 93, p. 251). The illustrations give a sufficient idea of their general appearance.

A NEW HALL FOR THE ROYAL HORTICULTURAL SOCIETY is becoming more and more urgent. The space the Drill Hall is capable of affording is by no means equal to the requirements of such an exhibition as that held there this week, when much confusion was inevitable. The number of separate committee meetings of various kinds more or less connected with the Society, held on the same day, is also very embarrassing.

ARABIS ALPINA.—The new double-flowered variety of this plant was exhibited at the Drill Hall show on Tuesday last.

ROSE FORTUNE'S YELLOW, is so finely exhibited at the Drill Hall each spring from the gardens of Lord WANTAGE, that we wonder a greater number of gardeners do not cultivate this variety successfully. The peculiar tint of the blooms, and their pleasing fragrance are always greatly admired. It is certainly worth planting in any garden that boasts a covered rosary, or even a greenhouse or conservatory where there are pillars to furnish.

A POISONOUS BOUQUET.—It is reported in the daily press that a lady in Omaha (Nebraska) was on the 13th ult. sent a handsome bouquet of flowers, together with a box of bon-bons. After smelling these flowers and partaking of some of the sweets, she became unconscious, and was reported to be dying. A subsequent examination showed that the presents had been impregnated with prussic acid. Seldom, we hope, have flowers been used for so diabolical a purpose; but the developments in this "poison by post" business are appalling.

THE DEVELOPMENT OF CYPRUS. — Colonel FYLER has published, through PERCY LUND, HUMPHRIES & Co., a little work dealing with the history and physical features of Cyprus. The island is so full of interest to the archæologist and naturalist that we scarcely think full justice has been done to it; the numerous illustrations with which the book is provided only whet our curiosity and make us wish for more. At present, we are told, there are no good hotels, else, Cyprus would be an excellent winter resort.

APPLE BEN DAVIS.—A writer in *American Gardening*, who draws attention to an instance in Nebraska where the public refused to buy this well-known American Apple, whilst other varieties were to be obtained, advises the orchardists to "Ship Ben to Europe." If "Ben" should arrive here in greater quantities than usual, we suppose the reason will be that the Americans have lost their conceit in this variety.

NEW YORK BOTANIC GARDENS.—Dr. D. T. MACDOUGAL has been appointed Director of the Laboratory of this establishment.

KEW.—In 1842 it was said of Kew that it was "a retired Hamlet," hamlet with a capital (see *Botanical Magazine*, t. 3922). It hardly answers to that designation now. At that time it was estimated that there were more Cedars in Britain than on Mount Lebanon itself, and more Cacteæ "than fall to the lot of any single empire or republic in all the Western World." At that time Woburn Abbey, Hendon, and Boyton House, Wilts, were the homes of great collections of these plants. LAMBERT presented his collection to Kew, just prior to his death. This took place at Kew, whither he had been removed to be near that Botanic Garden, in the prosperity of which he had always taken such a lively interest.

APPLES FROM THE ANTIPODES.—The officials of the Orient line of steamers advise us that the *Omrah* sailed from Adelaide on the 6th inst. with 28,000 cases of Apples; and was followed by the *India* from Adelaide on the 13th, with 17,000 cases of Apples.

FRITILLARY.—Mr. ELWES obligingly sends us numerous flowers of species of Fritillary, to show how little injured they were by 18° of frost during three successive nights. A flower of F. imperialis maxima measures 3 inches in depth, and is of a rich reddish-orange colour. The inodora variety differs from the others, not only in the absence of odour, but also in the more rounded perianth segments. It is of a very deep orange colour, strongly flushed with purple towards the base. Flowers of Lilium Thomsonianum, Erythronium, and Muscari accompanied the Fritillarias.

TO ENCOURAGE IN CHILDREN A LOVE FOR GARDENING. — In connection with the Hanley (Staffs.) Horticultural Fête, to be held July 5 & 6, there will be a children's section. The committee is now appealing for gifts of surplus plants or seeds for distribution amongst the children attending the elementary schools in the town. The plants will have to be grown by the exhibitors for a period of eight weeks previous to the exhibition. Such work has been practised with gratifying success in connection with the People's Palace in the East of London.

THE ROYAL GARDENERS' ORPHAN FUND.—We have much pleasure in making the announcement that Sir REGINALD HANSON, Bart., M.P., has consented to preside at the Annual Dinner of this charity, which will take place at the Hôtel Métropole, on Tuesday, July 18.

A CURIOUS PARASITE.—It may interest your botanical readers to know that Cynomorium coccineum, L. (Balanophoreæ), is now flowering in my garden; it is growing on the root of Atriplex portulacoides, L., and has sent up four heads. This extraordinary plant is a native of Sicily, Lampedusa, and Southern Spain; an excellent figure of it is to be seen in KERNER & OLIVER'S *Natural History of Plants*, vol. i., p. 197. *T. Hanbury, La Mortola, April* 15.

VANDALISM.—We had been gradually coming round to the belief that injuring flower-beds and the uprooting of shrubs, &c., had ceased to be apprehended. Of this idea we have been disabused. A short time since it was announced that Mr. CONINGSBY DISRAELI had been forced to close the gates of Hughenden because of the wanton damage

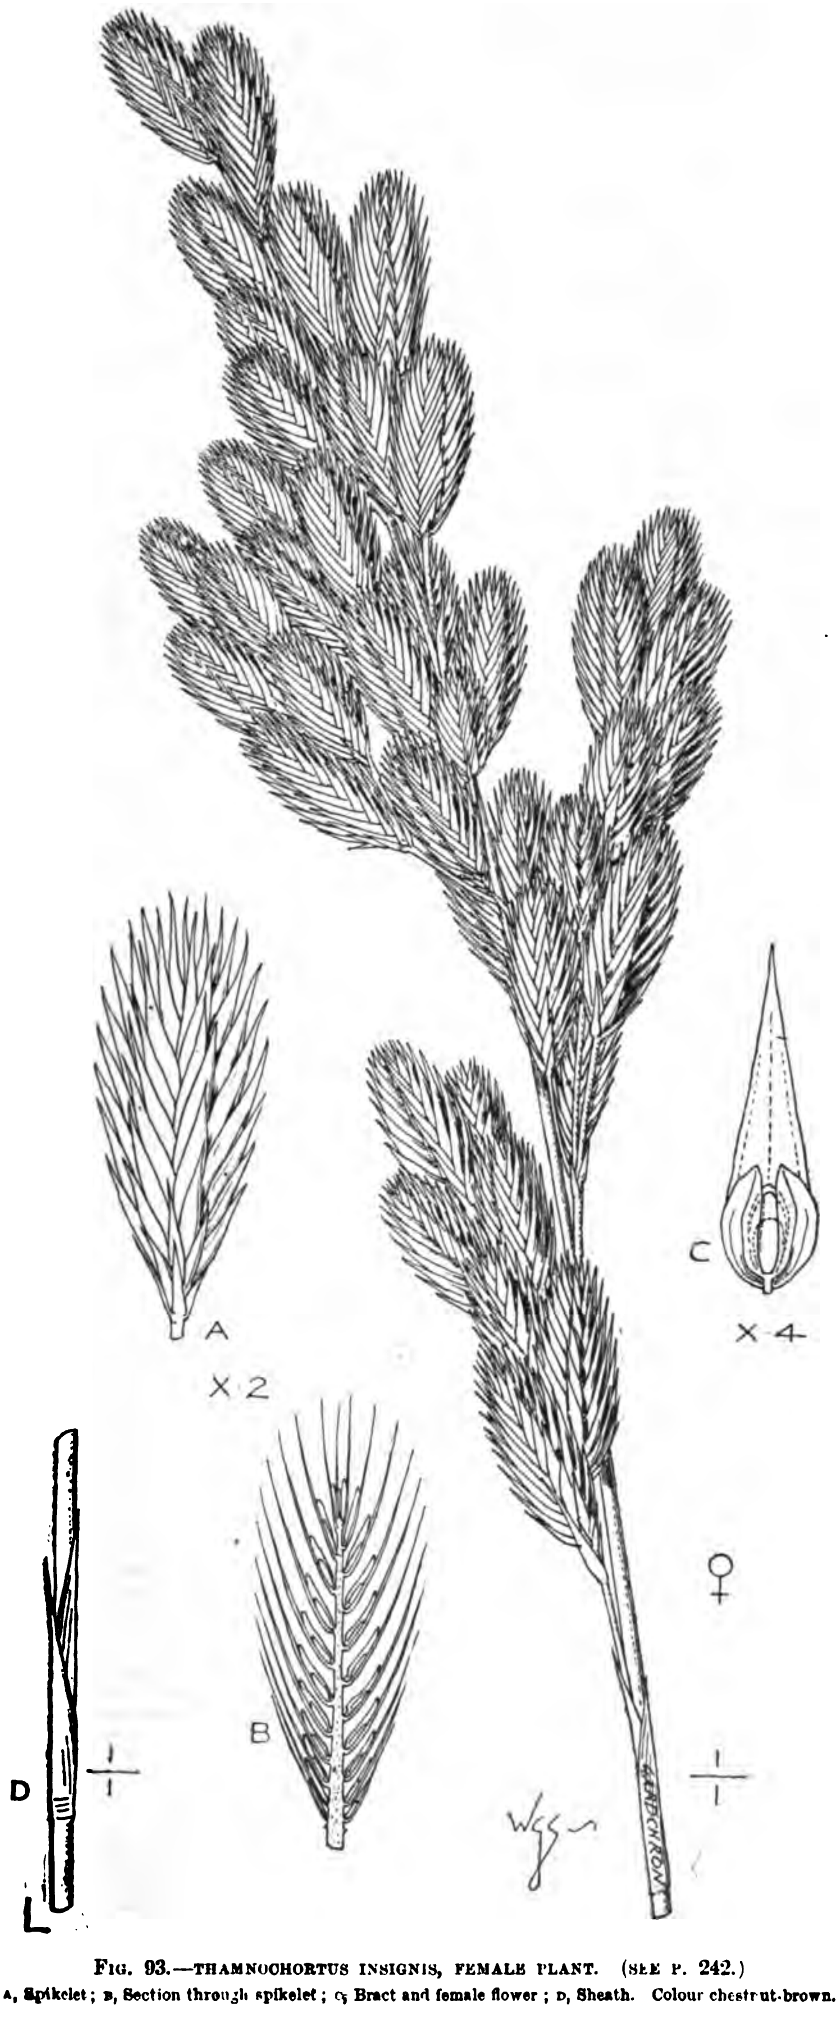

Fig. 93.—THAMNOCHORTUS INSIGNIS, FEMALE PLANT. (SEE P. 242.)

A, Spikelet; B, Section through spikelet; C, Bract and female flower; D, Sheath. Colour chestnut-brown.

done by visitors. To-day we are told that Lady Henry Somerset is, for the same reason, about to exclude the public from her beautiful park close to Reigate. Vandalism has been prominent during some years, many trees in the park suffering in one way or another. Very recently a large clump of Scots Firs planted near the gates has been most wilfully destroyed, saplings being pulled up by the roots; in one night there were thirty victims to this most wanton outrage.

A Floral Sword for Culloden.—A monster floral claymore was laid on Culloden Moor on April 16 by Mr. Theodore Napier, of Edinburgh. The handle of the "weapon" was composed of Myrtle, and the blade was formed of sphagnum-moss, with the words "What they fought for we will work for," picked out in bold red letters, formed of Gnaphaliums. A white satin ribbon is attached to the handle with the following inscription: "In honour of the brave men who fought on Drummore Moor in support of the rightful Sovereign of these realms—King James VIII.—April 16, 1746, from the Scottish members of the Legitimist Jacobite League of Great Britain and Ireland."

The "Hurst & Son" Musical Society.—The members of this Society, which was established at the beginning of the present year, in connection with the well-known firm of Messrs. Hurst & Son, gave their first concert at St. Botolph's Schools, Bishopsgate, on Thursday evening, 13th inst., before a crowded audience, when a capital programme of vocal and instrumental music was gone through. In the course of the evening, during an interval in which light refreshments were served, the President (Mr. N. Sherwood) briefly referred to the formation of the Society, its objects and aims, and expressed his pleasure in seeing such a large company. Judging from the success of this first public effort, it is safe to predict a prosperous future for the Society.

Chrysanthemums after Easter are scarcely likely to obtain the popular appreciation that is so liberally accorded to the flower during its natural season. Nevertheless, a correspondent has sent us yellow blooms, and a photograph of a plant of the variety Wilfred Marshall. It appears that the plant flowered early in January, and those now produced are a second crop—a by no means scanty one.

Flower and Fruit Farming.—Mr. Bear continues his essay on the production of flowers and fruits for market purposes in the *Journal of the Royal Agricultural Society*. Mr. Bear goes over much the same ground, but with fuller detail, than that which has been traversed by writers in our own pages, and in those of our contemporaries, but it is very serviceable to have the material collected in a form handy for reference. Perhaps Mr. Bear will reprint his essays in a separate form, which will be even more convenient.

Report of Observations on Injurious Insects.—The publication of a general index to the series of twenty-two annual reports prepared by Miss Ormerod, is announced. The index is prepared by Mr. Robert Newstead, and will be very convenient for purposes of reference.

Floral Devices.—An American gardener has represented in plants and flowers the battleship *Maine*. The model is one-sixth the actual size, and has a length of 53 feet, and a breadth of 10. More than 117,000 plants were used in its construction. We do not know whether to be more surprised at the labour this must have entailed or at the violation of good taste manifested—but then, tastes differ. The "battleship done in plants" is represented in the *Florists' Exchange*. Another device is thus described: Palmer & Son, of Buffalo, bedecked their window in a manner that turned out to be a good advertisement. A 5-feet diameter globe, skeleton framed of wire, covered with bronze Galax leaves, raised about a foot above the floor of their window, served as a foundation; effective in character. Directly on top of the globe a "buffalo" made of Violets, the details and proportions of which were carefully worked out, was posed. The outlines of the western continent were carefully planned and adjusted on a ground of Daffodils; pendent from the Pacific-ocean side of the globe, hung the now here traditional American pan, formed of Violets and ribbon bowed.

Dr. A. Zahlbruckner has been appointed to the provisional direction of the botanical section of the Natural History Museum in Vienna.

"The Gallovidian."—This is a new comer into the world of journalism, and as such deserves a welcome, more especially as its contents are bright and varied, and its "get-up" good. *The Gallovidian* is addressed principally to the dwellers in "Galfresia," a province that will not be found in the maps, but which has been devised to include the three southern counties of Dumfries, Wigton, and Kirkcudbright. The journal is markedly provincial, by which we mean patriotic. There is a good portrait of Sir Herbert Maxwell, together with a sketch of his career. The poets of the province are appropriately represented by the Rev. David R. Williamson, the writer of the articles in our columns entitled, "Notes from a Scottish Manse," with a view of the Manse of Kirkmaiden, and its well-stocked garden The poet and the man of science are at one in the feeling that—

"Glory everywhere
Is breathing from woodland flowers."

Aucubas.—To some of us it seems but the other day that Fortune introduced the male plant. In consequence of which our shrubs are now covered with berries, and in place of one variety we have them by scores. It may be suggested to raisers that they should endeavour to raise a variety which will throw its fruit well up above the foliage. At present it is often nearly concealed by the foliage; the Aucuba is one of the few plants that ripen their fruit in spring.

Our Benefactors.—We see in the current number of the *Journal of the National Horticultural Society of France*, a suggestion similar to what we have often advocated in these columns, viz., the desirability of commemorating in some form or another the names and achievements of our forefathers. We have just mentioned the Aucuba. Very few, we are convinced, know by whose agency this very valuable shrub was introduced, and the generation which witnessed the importations of Fortune is fast passing away; as has already that which was astonished by the profusion and interest of Douglas' discoveries. Addressing the members of the Paris Society, M. Ed. Roze advocates the commemoration of the name of Charles de l'Escluse (Clusius), of Arras, through whom the Potato was first introduced into France. To him also is due the introduction of the Laurel-Cherry, Prunus Lauro-cerasus.

Wakefield Paxton Society.—The weekly meeting of the members of this society was held at the Strafford Arms Hotel, on April 15, Alderman Milnes, J.P., presiding. The subject dealt with on this occasion was the "Daffodil: its History (briefly), Cultivation, Seed, and Seedlings," by Mr. W. H Garside, of Wakefield Park.

FOREIGN CORRESPONDENCE.

GARDENERS' WAGES IN GERMANY.

In your issue of April 1, there is an article on p. 194 referring to gardeners' wages in Germany. This article was written by an English youth whom I, on the recommendation of an old business friend in London, allowed to work in my establishment. After a very short experience, Mr. Cook thought himself already wise enough to write this letter; and as it is likely to throw discredit on the way workmen are paid here, I think it ought not to be left without a reply on my part. The wages which Mr. Cook states are perfectly correct. He only omits to mention that 10*s.* are the wages of lads of 16 to 18, and 15*s.* are the wages of grown men after they have been here a few years. Those who show special ability get up to 18*s.* or 20*s.*, and unusually gifted men much higher. One of my best foremen, a peasant's son, came here as a boy at 3*s.* or 4*s.* a week, and gets now a salary of £150 a year; two others get £135, and one £175. These wages are about the same, only somewhat better, than those paid in Belgium. In that country the boys of 14 years of age begin with 2*s.* a week. Here they begin with 4*s.* 6*d.* a week, and they get not one advance, as Mr. Cook says, but two yearly of 9*d.* a week. All the workmen are, of course, in the sick fund, and the firm pays half of their weekly contributions. There is, besides, a private fund at their disposal in special cases of emergency, and they receive besides a small Christmas present annually. The scale of remuneration is higher than it was ten years ago, but living has got dearer all round. It is lower than the wages of artisans (masons, joiners, locksmiths, &c.), who in this city get between 20*s.* and 28*s.*; but these have all gone through a term of apprenticeship, and have to provide their own tools, and are, especially the masons, dismissed when there is no work for them in winter. They live also in the town, whereas nine-tenths of my workmen live in the villages round Erfurt, where food, lodgings, taxes, &c., are considerably lower. I have a staff of about 200 people perfectly satisfied with their condition. Those who are not so, and leave, are easily replaced. The improvers, of whom Mr. Cook speaks, get indeed 45*s.* monthly to begin with. They generally stay in the Erfurt nurseries, like Mr. Cook himself, six to twelve months, in order to get an idea of the method of seed-culture, and then they mostly leave. They are only too glad to get situations here, where they have so much opportunity to learn and gain experience.

What Mr. Cook further says about England not being able to compete with Germany in seed-growing is such nonsense, that it needs no reply. England, on the contrary, is in many articles our chief competitor, and of a good many seeds we get our supplies from that country exclusively. *Ernst Benary, Erfurt.*

HOME CORRESPONDENCE.

Winter Salads (see p. 236).—I have read with interest Mr. Wythes' note concerning winter salads. Everyone knows with what ease Chicory and Dandelion may be grown and blanched, but an unbroken supply of tender Lettuces throughout the winter months is quite another matter, and it requires a great deal of skill to obtain even a fairly good supply. Much may be done by sowing seed at intervals throughout August and September, planting the seedlings well in the open, lifting when about to form hearts, and then transplanting them to cold frames or Peach-houses, doing the work when the leaves are dry. A good stock preserved in this way will afford salads for several weeks, the plants on all favoured occasions having abundant ventilation. A goodly number of the same-sized plants may be taken up, and placed in 8 and 10-inch pots, potting from four to seven plants in each, and close to the sides of the pots, with the lower leaves resting on the rims. In this way the leaves are not so liable to rot as when planted on the level. I have also tried them in heated pits, but no matter how careful I was with regard to forcing, airing, &c., I always failed in obtaining hearts of the Cos varieties. The early hearting Cabbage varieties, as All-the-year-round, and Hardy Hammersmith, are the best for this kind of over-wintering. I have had fairly good Lettuces very early in the season of the Black-seeded (Brown Cos) when planted close to the brickwork of a forcing-house on the south side. The heat from the house warming the earth and forcing the plants to grow, and from these plantings I was always able to cut Lettuces several weeks before those growing in the open border. It is, however, not practicable in this country to obtain good hearted Lettuces in the months of February and March with our present varieties. We want a Lettuce which may be forced without spoiling it, and which is not liable to go off with damp or lack of sunlight. Would not electric light, and heated large houses, help us? [Certainly the Americans are in advance of us in this particular. Ed.] *H. Markham.*

—— The August and September sowings would keep us going with "hearty" Cos and Cabbage Lettuces till the end of January, then the pinch would be felt. But as we English are not ravenous in regard to "green meat" in the dead of winter, and can manage to exist on ordinary meat-foods and seasonable vegetables not a few, for the period of February to April, should not the gardener be relieved of the useless attempt to grow Lettuces at that season? He has enough, as it is, piled upon his broad shoulders, but there is always someone proposing an increase to his burdens. Those who know only the needs of an ordinary establishment forty years ago, would be astonished at the increase of the gardener's duties, and at the same time the very noticeable reduction of garden labour at the present day. Even Lettuces could not be cultivated without expense in labour and fuel. Are they worth it?—that is the question. The gardeners of the south of France are willing to do all this for us, even as they now grow our early vegetables of all kinds, and the produce beats anything we can show at that season. I say, therefore, let them furnish the supply of Lettuce, for it is but a bagatelle; moreover, every increase of trade, in whatsoever direction, is a guaranty of peace between us and them. *Cui bono.*

Apple Barnack Beauty.—I have read in your issue of the 15th inst. of an Award of Merit being given to the above Apple by the Royal Horticultural Society. As I have grown large quantities of it for the last fifteen years, a few particulars respecting the variety may be of interest to many of your readers. The tree is very hardy and free from canker, growth upright, and great cropper. The fruit-spurs in young trees extend from the base for the whole length of the branches (excepting of course the one-year wood), and if grown on the Paradise stock the fruit is of high colour, and much larger than those from the Crab. When Apples are scarce in April and May, this variety is not to be despised as a dessert fruit, for it is very handsome, and does not shrink if well harvested. This excellent Apple was brought into commerce twenty years ago by Messrs. W. & J. Brown, nurserymen, at Stamford and Peterborough, who grow and sell a large number of the trees every year. The parent tree, a seedling, is still in a healthy condition in the garden of Mr. Charles, who resides in the village of Barnack, four miles from Stamford. Apparently it is from fifty to sixty years old. A few days ago Mr. Charles showed me the tree, and amongst other interesting information he told me that when late Apples were scarce one season, the Marquis of Exeter's late head gardener, Mr. Gilbert, bought 17 stone, the produce of this tree, for which he paid 7*s.* 6*d.* per stone. *A. Hagger, 3, Scotgate, Stamford, Lincolnshire.*

Primula sinensis causing irritation.—As your correspondent, E. Bonavia, M.D., seems to doubt the case mentioned by me in the *Gardeners' Chronicle* for April 1, I can assure him without a doubt that P. sinensis was responsible for the case in question. Four years ago my friend grew P. obconica, and on the leaves coming in contact with his hands he felt a sharp irritation, and a rash came out which went up his arms beyond the wrist. This kept on for several days; he tried ointments and other things, but to no avail. So last year he discarded P. obconica, and tried P. sinensis, and yet this species affected him in the same way; or, as he puts it, as badly as ever, if not worse, the irritation and rash extending to the elbow. Every time he touched the plant, the same thing occurred; and as further proof, one day a leaf accidentally touched his neck, and the irritation and rash appeared there. He also says that neither weather nor winds, no matter how severe they may be, ever affect his skin in any way. In *Amateur Gardening* for November 20, 1897, p. 327, you will find a writer there gives his experience of the two species of Primulas. He says that he has found several times during the last ten years that P. sinensis does cause irritation on the back of the hands and fingers when the plants are handled, and that the irritation is very great for two or three days; but, he adds, it is alleviated by using the following lotion, and then gives the recipe for same. Knowing my friend personally for many years as an amateur gardener, I have every confidence that what he states is a fact. The recipe I mention is made up of the following: R. Pulv. zinci oxidi ℨ ix., acid carbolic, gr. xxv., glycerine ℨ iv., aquam rosæ q. s. To be used frequently. This is a palliative. *J. R. Wilson, The Gardens, Haselbeck Hall, Northants.*

—— Mr. J. Mayne, in *Gardeners' Chronicle*, at p. 236, adds one more to the diverse opinions expressed from time to time of the effects produced by the leaves of Primula obconica on the skin. In my own case I dare not remove a leaf without wearing gloves, but all of the men in the gardens here are able to handle the plant without ill-effects following. My remedy for the irritation is to dip the hand or arm in water as hot as it is possible to bear, withdrawing it and repeating the dipping till the irritation is allayed. It would be a pity for the lack of a remedy to see this pretty plant discarded by the gardener. *T. Low, Hutton Hall Gardens, York.*

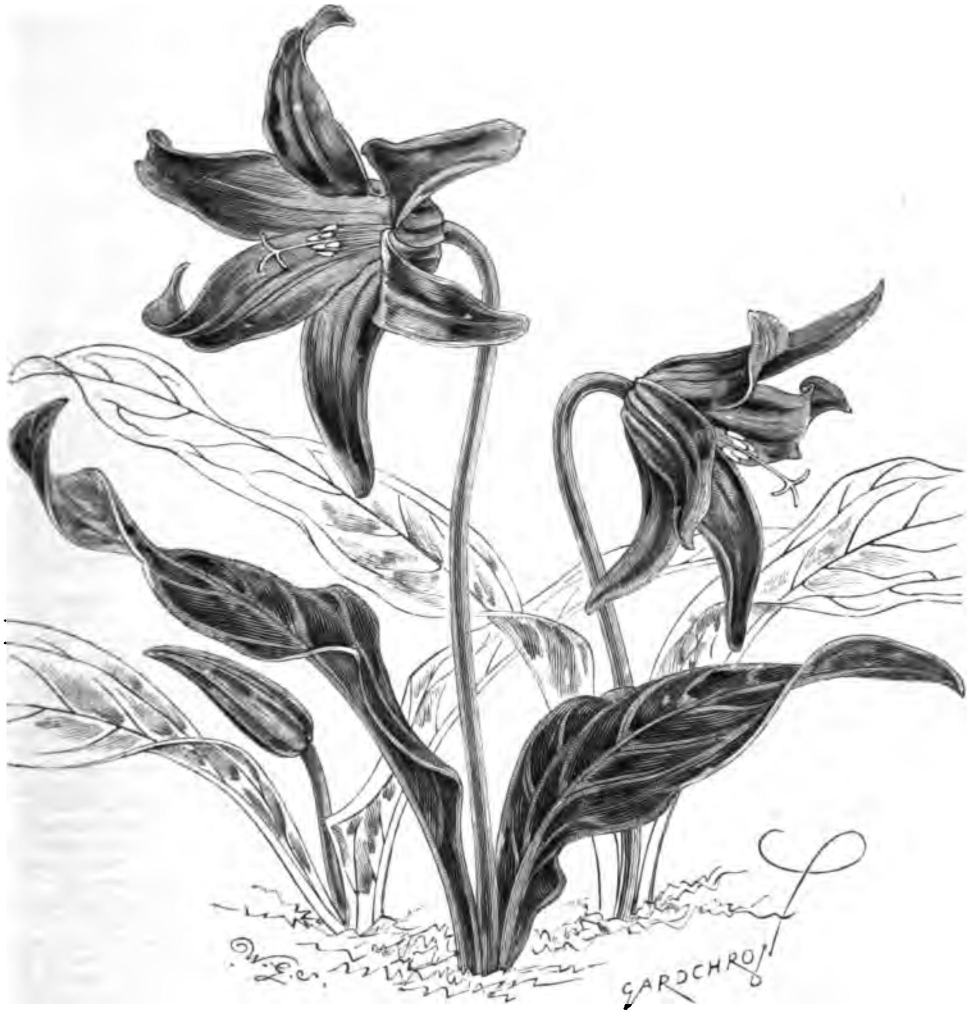

Fig. 94.—Erythronium Johnsoni: colour of flowers lilac rose.
(Awarded a First-Class Certificate at the Royal Horticultural Society's Meeting on Tuesday last.

THE NEWER FRENCH CLIMBING BEANS.—Under this heading may be classed some half dozen varieties that are earlier than the ordinary Runners, but which produce equally large crops of good pods. Such varieties are extremely valuable because they require such little space in the garden, compared with that needed by Runners. The first of this new type has been fully tested in many gardens, and I do not hesitate to say it will be largely grown in future, and whether known as Veitch's Climbing or Sutton's Tender-and-True, it is an excellent vegetable, and superior in dry seasons to the Runner. Since the advent of Tender-and-True, Messrs. Sutton have obtained some distinct varieties. Though some of these are stronger in their climbing habit than is Tender-and-True, the pods do not resemble in the least those of the Runner Bean, and they crop enormously. These climbing French Beans do well in most soils, their chief requirement being plenty of moisture. So good were these last season (which was anything but a propitious one), that I think it useless to continue to cultivate the older Runners. The pods of the former are most shapely, and when gathered in a young state are of the finest quality, and are more readily prepared for use. Now, as to the little space they require. Most of the varieties succeed if given half the space between the rows usually afforded the Runner Beans. I have grown them at 4 feet apart, but if room can be allowed 6 feet is better. We stopped the plants when they had reached a height of 4 feet, and I have never seen such excellent results. The plants set pods quite close to the soil, and continued to do so from new breaks higher up the bine till cut down by frost. Many growers dislike dwarf Beans in the late summer months, on account of the pods getting old and stringy so quickly, but the newer type yield more fleshy pods, and combine the vigour of the Runner with the shapely pod of the French type. Such dwarfness with equal weight of produce is a step in the right direction. It was not always an easy matter to obtain an ample supply of Bean-rods, but this type of Bean can be grown with ordinary Pea-sticks from 4 to 6 feet in height; or if desired, they may be stopped at even less than the height given, if such kinds as Tender-and-True, Sutton's Earliest-of-All, or Epicure, be grown. The first-named variety, and the variety that found so many admirers at the Royal Horticultural Society's Gardens at Chiswick a few years ago, is still one of the best, and has been found to be synonymous with Veitch's Climbing, which was sent to the Society's Gardens by Mr. H. W. Ward. Earliest-of-All is a distinct variety of later introduction, and bears remarkably early. It belongs to the white-seeded section, and I have found the white-seeded varieties of the Runner to be rather earlier than the others. It has a very fleshy pod, and is almost free from the stringyness so characteristic of the Runner Bean. Earliest-of-All crops equal to any of the varieties, and if gathered in a young state and cooked whole it is delicious. Epicure is late, but it is of great value for summer cropping; it bears in large clusters light green pods of splendid table quality, far superior, in my opinion, to the best Runner. Excelsior is a larger grower, and the strongest of the new Runner varieties, and specially good for late summer and early autumn supplies. This variety will grow 10 feet in height, but we stop at 6 feet, and grown thus it will fruit into November in a mild season. *G. Wythes.*

A BLACKBIRD'S NEST IN A PONY'S BOOT.—The nests of birds, as we know, are often constructed of strange materials and in strange places, and one that I found this morning shows it: on going into the shed in which the mowing machines and pony's boots are kept it was discovered that a blackbird had built her nest in one of the latter, which hang on the wall. Having to use the boots, I put the nest in a small box and hung it on the same peg, and the blackbird has laid another egg in it, and is sitting quite contentedly to-night. *A. E. Matthews, Court Colman, Bridgend.*

HARDY FLOWERING SHRUBS.—At Sion House, and also at Gunnersbury House, the Chinese Yulan, or Water Lily-tree (Magnolia conspicua), is just now very effective, having, owing to the lateness of the season, escaped spring frosts and the recent rude winds. At Kew just at this moment M. stellata and other kinds are beautiful; but the one hardy shrub that now lights up the Royal gardens like gleams of "sunshine in a shady place," is the Chinese Forsythia suspensa, for which we have to thank the Royal Horticultural Society, and the late Robert Fortune. It is one of the shrubs that is good in all ways, as a bush, as a group, on a wall, or on trees or rocks, and should more often find a place on Ivied walls than is at present the rule. Even as a pot-plant for the cool greenhouse, it is most useful, grown as Wistarias are at Kew, and the Laburnum as at Highbury. Daphne Mezereum, both purple and white, and single and double-flowered Peaches, are also now flowering at Kew. The Amaryllis, or Hippeastrums, and Japan Tree Pæonies are now very showy at Kew in the No. 4 greenhouse, where there are also one or two very large and well-grown groups of Cineraria cruenta varieties, as free in habit and as graceful as are the best of the autumnal Michaelmas Daisies or Asters. In the conservatory at Highbury, Birmingham, the other day I saw a very well-grown and handsome group of double German Wallflowers in pots, and varieties of Schizanthus pinnatus were also very effective there. Coming by rail through Berkshire and Herts the other day, the Plum-orchards were white with snowy-petalled flowers; and the same is true of the orchards and market-gardens that lie between the church spire at Turnham Green and the classical water-tower of Brentford. Now that our little "Black Thorn Winter" is over, I hope we may have a flowery and a fertile spring. *F. W. Burbidge.*

SOCIETIES.

ROYAL HORTICULTURAL.

April 18.—Those who frequent the meetings of the Royal Horticultural Society at the Drill Hall, Westminster, have come to regard as a red-letter day the particular date each year when the National Auricula Society hold their exhibition in conjunction with the ordinary fortnightly meeting. But even after allowing for this, the meeting on Tuesday last was a record one. Never do we remember to have seen the Hall so inconveniently crowded with exhibits and visitors. There was quite insufficient space to stage the exhibits properly (though a word of praise is due to Mr. Wright for having done this to the best degree possible), and the pathways were so thronged that visitors themselves had great difficult in inspecting the plants. As to the representatives of the

Press, their efforts were made under difficulties that they would regret to see become permanent. But there was noticeable that enthusiasm that seems peculiar to large gatherings, and notwithstanding the inconvenience, and the fact that the afternoon lecture had to be postponed on account of the crush, the day was, no doubt, a very enjoyable and interesting one to most of the exhibitors. The Auricula Exhibition, which was better than had been expected, is fully reported below.

The Orchid Committee recommended two First class Certificates and three Awards of Merit, three of the distinguished plants being Odontoglossums, the others a Masdevallia and a Dendrobium. Two First-class Certificates were awarded by the Floral Committee to a beautiful hybrid Anthurium from Sir Trevor Lawrence, and to a pure white variety of Anemone blanda from the Duke of Rutland's garden. The only Award of Merit made was to Erythronium Johnsoni, a species figured in these columns so long ago as 1896, from Messrs. Wallace & Co. Among the new plants before this committee also may be mentioned the double-flowered variety of Arabis alpina.

The Narcissus Committee had considerable work to discharge, the exhibits of Daffodils being numerous and extensive. The hybrids from the garden of the Rev. Geo. Engleheart were much admired.

The awards recommended by the Fruit Committee were to Pea Carter's Early Morn, Onion Ne Plus Ultra, and Tomato Winter Beauty.

Floral Committee.

Present: W. Marshall, Esq., in the chair; and Messrs. John Fraser, Chas. T. Druery, Owen Thomas, H. B. May, R. Dean, J. H. Fitt, Geo. Nicholson, W. Howe, John Jennings, R. B. Lowe, Thomas Peed, R. Wilson Ker, Geo. Paul, W. Bain, J. D. Pawle, C. R. Fielder, Herbert J. Cutbush, J. W. Barr, E. T. Cook, E. Beckett, T. W. Sanders, D. B. Crane, E. H. Jenkins, C. Blick, H. Selfe Leonard, H. J. Jones, Harry Turner, and Ed. Mawley.

CINERARIAS.

Messrs. J. Carter & Co., High Holborn, London, showed Cinerarias in a group upon the floor. As a collection of the ordinary florists' type, it represented a strain of very considerable merit, producing large and brilliantly-coloured flowers of great variety of tint. Another group from the same firm was composed of double-flowered Cinerarias, and the plants, in this case, showed excellent cultivation, being of good habit, and bearing a goodly number, each of fine flowers in distinct colours (Silver Banksian Medal).

Messrs. Sutton & Sons, Reading, showed a group of plants of the hybrid Cinerarias, now named "Stellata" strain, or "Star Cineraria." This collection represented considerable advance since last season, when the firm made a similar display. They have obtained a more even type. Individually the little flowers are perfect, and in their way the plants have as good habit as those of the florist's varieties. A greater variety in colour is evident; indeed, in this respect they appear to be equal to their more showy relatives. From the florist's point of view, however, they are and must remain "weeds," although the decorator will not fail to appreciate such weeds. The flowers are exceedingly numerous, uncrowded, and perfectly erect, and when cut they therefore display themselves to the best possible advantage. It is probably more due to cultivation than anything else, that the plants shown were only from 14 inches to 2½ feet in height. If the same plants had been given more root room, and fed liberally, they would probably have trebled their stature, but the exhibit showed that it is quite possible to obtain them as dwarf as needful (Silver Flora Medal).

ROSES.

Messrs. Paul & Son, The Old Nurseries, Cheshunt, showed some Roses in pots, including Perle d'Or, a pretty little Polyantha variety; Muriel Grahame, a new Tea, that has already won much favour; also Souvenir de S. A. Prince, a white Tea; Crimson Rambler, and several garden varieties of Rosa.

A variegated form of R. Wichuriana was shown with long growths; the Dawson Rose, a climbing Polyantha variety, with rose-coloured semi-single flowers; various other well-known sorts, and standards of same. A few hardy plants in flower were also from Messrs. Paul & Son.

Mr. W. Rumsey, Joynings Nurseries, Waltham Cross, Herts, made a commendable exhibit of Roses in pots, and these were faced by something like fourteen dozen cut blooms of popular varieties. Among the pot-plants were Magna Charta, Beauty of Waltham, Mrs. Rumsey, Miss Hassard, Madame Hoste, Crimson Rambler, and Heinrich Schultheiss.

From Lord Wantage's garden at Wantage, Mr. W. Fyfe again made a glorious display of blooms of the Rose Fortune's Yellow. The stems are rather weak, and were wired, there being from eight to a dozen blooms arranged in each glass. The peculiar tint of this Rose invariably attracts great appreciation.

A very prettily tinted Tea Rose, named Sunrise, was shown by Mr. G. W. Piper, Uckfield, who had a nice lot of flowers and buds. The colour reminds one of Empress of Russia, but is more intense.

HIPPEASTRUMS.

Some Hippeastrums from Mr. David Kemp, gr. to Wilberforce Bryant, Esq., Stoke Park Gardens, Slough, showed what extraordinary vigour is sometimes attained by seedlings. The plants were from seeds sown in 1893 and the following year, and they have never been plunged or given bottom-heat. These Chelsea hybrids were indeed monsters. In one 10-in. pot were bulbs that bore fifty flowers. The spikes commonly bore five or six large blooms, but occasionally there were seven and eight to an umbel. Some of the spikes were about 3 feet in length, and of wonderful strength (Silver Banksian Medal).

TULIPS.

A large number of Tulips in pots were shown by Messrs. W. Paul & Son, nurserymen, Waltham Cross. There were three to four bulbs in each pot, and the display that they made was good of its kind, and indicated what uses pot Tulips could be put to when grouped in masses of one colour, and contrasted with other plants as dwarf or dwarfer than themselves. Of varieties with which amateurs are unfamiliar, may be mentioned Van Berghem, a fine rosy-crimson bloom; Leonardo da Vinci, an orange red; La Matelas, a fancy pink, with white margin to the petals; Spandouck, a rose bizarre; La Matador, a double-crimson self; Grenadier, a red bizarre; Colour Cardinal, a self of rich crimson; Molière, an unbroken flower; Princess Helène, a pure white self, single, cerise; Gris de Lin, a bizarre; Thos. Moore, a striking orange-scarlet self; Epaminondas, deep crimson, single; Golden Lion, a yellow self; and Rosa Mundi, golden, a new bizarre. The display of Tulips was separated from other exhibits by a row of Cytisus, in variety, and forced, double-pink flowered Thorns.

MISCELLANEOUS PLANTS.

Mr. H. B. May's group from Dyson's Road Nursery, Upper Edmonton, was a display of spring-flowering plants, intermixed with Ferns. Crimson Rambler Roses in 6 and 7-inch pots were full of flower, and Hydrangea Hortensia var. Thomas Hogg, Spiræa astilboides floribunda, and a new mauve or purple-flowered Clematis named Nellie Moser, were good. Vitis heterophylla, a cold greenhouse species, with delicately ornamental foliage, was conspicuous amongst the foliage plants and choice Ferns employed to relieve this very beautiful exhibit (Silver-gilt Flora Medal).

Camellias grown in the open air near Windsor were shown in the shape of cut blooms by Sir Francis T. Barry, Bart., M.P., St. Leonard's Hill, Windsor (gr., Mr. R. Brown). There were upwards of 100 fine blooms, in several varieties (Bronze Banksian Medal).

A group of miscellaneous plants was contributed by Messrs. B. S. Williams & Son, Upper Holloway, London, N. In this exhibit there were remarked many pretty Ericas, Boronias; and of Cliveias, Van Houttei and Ambrose Verschaffelt; Erica perspicua erecta, and E. p. nana, are very pretty distinct-flowered Heaths. Acacia Drummondi and Acers, in several varieties, were attractive.

Messrs. W. Cutbush & Son, Highgate, London, N., demonstrated the decorative qualities of Acacia cordata, Ericas erecta and Cavendishi, the pure white Heath, E. candidissima, E. ventricosa, and the large, red-flowered E. hybrida; also Boronias heterophylla and megastigma. Some plants of the Otaheite Orange were exceptionally well fruited. Altogether, the group was an exhibition of fine culture applied to these free-flowering greenhouse plants, that have not merited the neglect to which they are now treated (Silver Banksian Medal).

Mr. John Russell, Richmond Nurseries, Surrey, showed a pretty group of the hardy Azaleas, and standard plants of Wistaria sinensis, forced Lilacs, &c.

Messrs. R. & G. Cuthbert, Southgate, Middlesex, showed a beautiful collection of Indian Azaleas, in nice dwarf plants, freely flowered, and many of them new. Roi de Hollande, Lima, Madame Chas. Van Elkhaute, Konigin Cleopatra, Superba, Oswald de Kerchove, and Memoire de Louis Houtte are all capital coloured varieties; and of pure white ones, such as Madame J. E. Planchon, Niobe, Deutsche Perle, and Raphael, were commendable.

Messrs. Wallace & Co., Kilnfield Gardens, Colchester, showed a number of varieties of Erythroniums and Fritillarias.

Messrs. John Laing & Sons, Forest Hill Nurseries, London, S.E., were awarded a Silver-Gilt Flora Medal for a magnificent group of miscellaneous plants. In this collection were splendid Boronias, Ericas, Azaleas, Anthuriums, the yellow-flowered Richardia Pentlandi, Acacia cordata, Codiæums, Cordylines, and choice Ferns. It was a tasteful arrangement of very choice plants.

Messrs. J. Peed & Sons, Roupell Park Nurseries, Norwood Road, S.E., staged a group of miscellaneous plants, in which were tuberous-rooted Begonias just commencing to flower, Caladiums, well-fruited Orange trees, Lilium candidum, and other species of decorative plants.

Myosotidium nobile, the gigantic Forget-me-not-like Boraginaceous plant from the Chatham Islands, and figured in the *Botanical Magazine*, 5137, and in the *Gardeners' Chronicle*, May 1, 1897, p. 293, was shown by Mrs. E. Powys Rogers, Burncoose, Perranwell, R.S.O., Cornwall. The flowers are white, with blue centres, about half an inch across, produced in large racemes.

Lotus Bertholeti in flower came from Major Thurlow's garden at Buckham Hill House, Uckfield (gr., Mr. Davis).

A much variegated variety of the hardy Deutzia, D. crenata, came from Mr. E. Beckett, gr. to Lord Aldenham, Elstree.

Mr. W. Camm showed, from the gardens of the Duchess of Cleveland, Battle Abbey, a pale-coloured variety of Bougainvillea speciosa.

H. J. Elwes, Esq., Colesbourne, contributed some pretty varieties of the Fritillary, Crown Imperial, including the maxima variety Muscari, &c.

Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea, showed plants of the new double-flowered Arabis alpina, a variety that will be much prized. Also blooms of a tinted variety of Magnolia stellata named rosea; and a variety of Philadelphus Lemoinei, known as Manteau de Hervæne.

Messrs. F. Sander & Co., St. Albans, exhibited a plant in flower of Dianthera illustris, an Acanthaceous plant, superficially resembling a Jacobinia, the bracts of the plant shown being dull red, and the flowers purple.

AWARDS.

Anthurium × *Perfection.*—Another of the beautiful hybrid Anthuriums raised by Sir Trevor Lawrence, Bart., Burford, Dorking (gr., Mr. Bain). Perfection is of the type of A. Andreanum, and has a coral-scarlet spathe, about 7 inches by 5 inches. The white spadix is about 4 inches long (First-class Certificate). Sir T. Lawrence exhibited other very handsome hybrids.

Anemone blanda var. cypriana.—A pure white variety of the type, the petals bearing blue only on the outer side (First-class Certificate), from Mr. W. H. Divers, gr. to the Duke of Rutland, Belvoir Castle, Grantham.

Erythronium Johnsoni.—A lilac-rose-coloured species, with yellow ring at the interior base, from the Coast Ranges of Southern Oregon. The flowers, which are borne upon scapes occasionally 10 inches in length, are about 2 inches across, and the segments widely expanded. The plant has two leaves, 5 to 6 inches long by 1½ inch wide, and much mottled. A fine illustration of this beautiful Erythronium was given in these columns, May 2, 1896, p. 549, (which is here reproduced), together with the original description published by Dr. Bolander in *Erythea*, vol. iii., August, 1895, p. 127.

Narcissus Committee.

Present: Messrs. J. T. Bennett-Poë, Chairman; C. R. Scrase-Dickins, Secretary; A. Kingsmill, J. Walker, W. Goldring, J. Pope, J. H. de Graaff, P. R. Barr, Hon. John Boscawen, R. Sydenham, J. Titheradge, Rev. G. H. Engleheart, Rev. S. E. Bourne, T. Marsh, and Miss Willmott.

Both Daffodils and those specially interested in their cultivation, were present on this occasion in unusual force, the flowers, after long hanging fire, have come in with a rush. Several large banks of cut bloom formed a feature of the day's exhibition, and a long session was provided for the committee by the number of new varieties submitted.

A large bicolor trumpet from Messrs. Barr, named Duke of Bedford, received an Award of Merit; though lacking the refined colour and form of Weardale Perfection, it is a strikingly handsome flower. The same award was given to Sunset, from Messrs. Barr, an apparent hybrid between Tazetta and Jonquilla; it has a clustered scape, orange cup, and yellow divisions. Messrs. J. Pope & Sons, King's Norton, gained an Award of Merit for Pope's King, a large and solid Ajax in the way of Golden Spur.

The Rev. G. H. Engleheart received a First-class Certificate for Edmonds' White, a large flower, which must be classed with N. Leedsii. It has a white perianth, and widely-expanded and fringed cup of pale lemon, very beautiful. The following flowers from the same exhibitor obtained Awards of Merit:—Flambeau, an incomparabilis of good size, with yellow segments, and brilliant orange crown, the colour finer than in Gloria Mundi. The plant is said to be exceptionally vigorous and free. Brigadier may be described as a bicolor Sir Watkin, a flower of the largest size, with broad white divisions, and large crown of deep yellow. Cassandra, one of Mr. Engleheart's well-known strain of seedling Poeticus, the flower noticeable for its amplitude of broad white petal and deep crimson eye. Strongbow, a Nelsoni-like form, with broad divisions, very stout, and well imbricated, the crown expanded, deep yellow tint, and of great substance.

A large group of Mr. Engleheart's seedlings seemed to draw a constant throng of visitors throughout the day. Besides the varieties mentioned, it contained many selected forms, representative of the advance he has made in colour, form, and size, beyond the older Narcissi. The depth and vividness of the red in many seedlings, was a remarkable feature; the stand also contained many beautiful pale flowers of the Leedsii class, and several large gatherings of the new Poeticus.

Messrs. Barr had, as usual, a grand collection of all Narcissi in flower at the date, the trumpets Weardale Perfection, Duke of Bedford, and Madame de Graaff, were especially fine. (Silver-gilt Flora).

Messrs. Pearson, of Chilwell, showed a large group, noteworthy not only for the splendid size and finish of the flowers, but also for the taste and skill displayed in their staging, a point in which they always excel.

Messrs. Bath, of Wisbech, exhibited a large bank of Narcissi in almost countless variety, and beautifully fresh.

J. T. Bennett-Poë, Esq., won Messrs. Barr's Silver Cup with a choice collection in exquisite condition.

J. W. Jones, Esq., Invermore, Woking, had a fine display in considerable variety. He was 2nd in the Cup Competition.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. S. Courtauld, J. Colman, E. Ashworth, W. H. White, H. T. Pitt, E. Hill, J. Jaques, F. Sander, T. W. Bond, W. H. Young, A. Outram, H. Little, J. Gabriel, H. J. Chapman, H. Ballantine, De B. Crawshay, J. G. Fowler, T. B. Haywood, and Jas. O'Brien (Hon. Sec.).

The hall was so full of cut flowers and plants, among which the Orchids formed an important feature, that most of the exhibitors who entered items which they desired to go before the committee had to be placed on the committee table.

Odontoglossums formed the main feature. Fashion for some years past has constituted rare varieties and richly-spotted forms amongst the most valuable of Orchids.

Baron Sir H. Schröder, The Dell, Staines (gr., Mr. H. Ballantine), sent fine examples of his grand collection in the still unsurpassed violet-spotted Odontoglossum Pescatorei Schröderianum, and O. P. Veitchianum; the magnificent O. × Wilckeanum Queen Empress; the remarkable brownish-purple blotched O. crispum Princess Christian, distinct both in plant and flower; a noble form of O. triumphans, &c.; also a fine inflorescence of the singular blue-tinted Cattleya Lawrenceana Vinckei (Silver Flora Medal).

Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), also had in his pretty group some very fine Odontoglossums, notably a grand form of O. × Ruckerianum, with a five-branched spike; O. × Andersonianum, Dorman's variety, a splendid cream-white flower, heavily blotched with red-brown; an excellently-cultivated plant of the rare O. coronarium miniatum, with two fine spikes; a fine form of O. gloriosum; remarkable O. crispum, O. Edwardi, two fine spikes; and other fine varieties; and of other species the rare scarlet Epidendrum Schomburgkianum, with two spikes; three plants of the elegant white and violet E. Endresii, additionally remarkable in that they were the same plants bearing the same flowers shown in February; Masdevallia × Shuttryana, Chamberlain's variety; varieties of M. Harryana; Cymbidium Devonianum, with five spikes; Maxillaria præstans, with nine flowers; Lælio-Cattleya × Highburyensis, Cypripedium × Fowlerianum, Cochlioda sanguinea, Dendrobium Falconeri giganteum, Miltonia cuneata, with five spikes (Cultural Commendation), Calanthe veratrifolia, with seven spikes, &c. (Silver Flora Medal).

A. Warburton, Esq., Vine House, Haslingden, showed another triumph in blotched Odontoglossum crispum Luciani, one of the handsomest and most richly purple-blotched forms extant, and which previously received a First-class Certificate, and was illustrated in the *Gardeners' Chronicle*, April 24, 1897, p. 268. The excellent culture accorded the plant by Mr. Warburton's Orchid-grower has still added to its beauties. There were also shown Dendrobium × Clio, Vine-house variety; Cattleya Schröderæ and C. Mendeli.

Elijah Ashworth, Esq., Harefield Hall, Wilmslow (gr., Mr. Holbrook), showed his splendid purplish-rose blotched Odontoglossum crispum Ashworthianum (see list of Awards), the fine Cypripedium Lawrenceanum Hyeanum superbum, and C. callosum Sanderæ Ashworthianum.

Dr B. Crawshay, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), again showed the noble Odontoglossum triumphans Lionel Crawshay, previously certificated and illustrated in the *Gardeners' Chronicle*, April 20, 1895, p. 489; the fine yellow flowers are the largest and have the broadest segments of any form of O. triumphans, the species not having another comparable with this one. The plant bore two fine spikes from one bulb, the one with ten and the other seven flowers, of the typical form. The exhibitor showed likewise O. triumphans princeps, fine in shape, and richly coloured.

Messrs. J. Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, staged the finest group, and were awarded a Silver-gilt Flora Medal. The centre consisted of a number of varieties of Cattleya Schroderæ, with flowers varying from whitish to shades of peach and rose colour, the orange tint in the throat varying considerably. With them were several fine forms of Cattleya Mendeli, C Schilleriana, the bright scarlet Epiphronitis × Veitchi, the white and rose Chysis × Chelsoni, Cymbidium × eburneo-Lowianum, Dendrobium × Alcippe, the new Cowslip-yellow D. × Imogen (signatum ♂, crassinum-leucopterum ♀), D. × Cheltenhamense, D. infundibulum, D. subclausum, and other species and hybrids; Lælia × Latona, L. cinnabarina, Lælio-Cattleya × Pallas, the pretty white Bifrenaria Harrisoniæ candida, a number of good Odontoglossums, Cypripediums, Cattleyas, &c.

Major Joicey, Sunningdale Park, Sunningdale (gr., Mr. F. J. Thorne), was awarded a Silver Banksian Medal for a finely-cultivated group of plants of Epidendrum bicornutum, which Mr. Thorne has succeeded in making thrive for several years past. Some of the plants showed four fine heads of flowers. With them came a plant of Angræcum sesquipedale with nine flowers, one of the spikes bearing four blooms; a vigorous example of the white-flowered Dendrobium Johnsoniæ, also its congener, D. atroviolaceum, was cultivated admirably.

J. Bradshaw, Esq., The Grange, Southgate (gr., Mr. Whiffen), staged a group, the back of which consisted of specimens of Cymbidium Lowianum, and the front of C. × eburneo-Lowianum; and beside these were noted good forms of Odontoglossum crispum, O. Pescatorei, O. × Andersonianum, O. triumphans, O. × Andrianæ, Lælia × Latona, Lycaste Skinneri, Cattleyas, &c. (Silver Flora Medal).

Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), showed the singular Odontoglossum × "Golden Sheen," a clear yellow hybrid, bearing a few reddish spots, and having some resemblance to the rare O. Leeanum; varieties of O. × Adrianæ; the handsomely-blotched O. crispum "Sir Frederick," &c.

Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. Wm. Murray), again showed a fine form of the charming Dendrobium × Cybele Oakwood var. (Findlayanum × nobile Burfordiense), the present form showing remarkably the lip-like colouring of dark purple and yellow on the lower sepals as in D. nobile Burfordiense. The flower segments are tipped with carmine-rose; the colour of the disc of the lip is dark purplish-crimson.

Messrs. Hugh Low & Co., Bush Hill Park, Enfield, secured a Silver Banksian Medal for an effective group in which the varieties of Cattleya Mendeli were well represented, also Odontoglossum crispum, O. triumphans, Dendrobium Falconeri giganteum, D. thyrsiflorum, Cattleya Schroderæ, Ada aurantiaca, &c.

Messrs. B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway, staged a large group, the centre of which consisted of eighteen well-grown and flowered plants of varieties of Vanda tricolor, and suavis including "The Glen variety," insignis and superba—a very unusual exhibit in recent times. Other plants were a selection of hybrid Cypripediums, Odontoglossums, Dendrobiums, Cymbidiums, Devonianum, Phaius × Norman, Trichopilia lepida, &c. (Silver Flora Medal).

W. A. Bilney, Esq., Fir Grange, Weybridge (gr., Mr. Whitlock), was awarded a Silver Banksian Medal for a fine group, principally of grandly-grown Dendrobium nobile, D. Wardianum, &c.

Walter Cobb, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes), showed Cypripedium caudatum Moensii, C. Rothschildianum, Dulcote var., very dark in colour, and other Orchids.

Mr. Jas. Douglas, Edenside, Great Bookham, showed a group, in which were good Cypripedium villosum, C. Rothschildianum, Phaius × Cooksoni, &c.

W. A. Gillett, Esq., Fairoak Lodge, Bishopstoke, sent a small collection of splendid examples of cut spikes of Orchids, all remarkable for the evident vigour of the plants from which they were taken, especially the Odontoglossums which comprised one very fine O. Pescatorei, two good O. crispum; a very handsome O. × Coradinei, with eighteen flowers; O. × Andersonianum, of great beauty; O. triumphans, O. Halli xanthoglossum, two O. Rossii majus; a fine form of Vanda suavis; four good Dendrobium nobile, cut on the pseudo-bulb, one with carmine tips to the segments, specially distinct, and a nearly white form, also good, and a fine example of Dendrobium Wardianum.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr., Mr. J. Davis), showed Cattleya × Cecilia (Lawrenceanum × Trianæi), also known as C. × Louis Chaton; and C. intermedia, "Fowler's var."

J. Sparkes, Esq., Heathside, Ewhurst (gr., Mr. D. Smith), showed a fine Cymbidium canaliculatum with several spikes.

G. O. Sloper, Esq., Highworth, showed a good Vanda tricolor, and Cypripedium × Dauthieri variety.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), again showed his magnificent Odontoglossum × excellens, Rosslyn variety.

Mrs. Parr, The Cedars, Upper Tooting, sent a form of Dendrobium macrophyllum.

F. M. Burton, Esq., Gainsborough, sent Cypripedium × Tautzianum lepidum.

Frau Ida Brandt, Riesbach, Zurich (gr., Mr. Schlecht), sent a finely-coloured Phalænopsis Luddemanniana, Lycaste candida Lawrenciana, Kiefersteinia graminea, &c.

AWARDS.

Masdevallia × Shuttryana, Chamberlain's variety (Shuttleworthi × Harryana var.).—One of the prettiest of hybrid Masdevallias, and quite distinct from the original M. × Shuttryana. The well-grown plant shown had a number of large rosy-mauve flowers with reddish tails. From Sir Trevor Lawrence, Bart. (First-class Certificate).

Odontoglossum crispum Ashworthianum, illustrated in the *Gardeners' Chronicle*, Feb. 16, 1896, p. 197.—A grand variety of the O. c. Baroness Schröder, and O. c. Frantz Masereel section, the greater part of the flower being bright rose-purple, relieved by slight irregular white lines and margin. From Elijah Ashworth, Esq. (gr., Mr. Holbrook). (First-Class Certificate).

Odontoglossum × Adrianæ "Lady Wigan" (O. Hunnewellianum × O. crispum). —A very pretty and distinct form with cream-white flowers, densely spotted orange-brown, and with the pretty crimped lip of O. Hunnewellianum. From Sir Frederick Wigan, Bart. (gr., Mr. W. H. Young). (Award of Merit.)

Dendrobium × Clio, Vine House variety (Wardianum × splendidissimum grandiflorum).—A fine form of this varying hybrid, in which the colouring of the lip approaches that of a good D. Wardianum. The inflorescence bore four flowers. From A. Warburton, Esq., Vine House, Haslingden (Award of Merit).

Odontoglossum Andersonianum obstupefaciens. — Flowers large, cream-white, with irregular curved blotches of red-brown. From C. J. Lucas, Esq., Warnham Court, Horsham (gr., Mr. Duncan), (Award of Merit).

Maxillaria Turneri.—Flowers allied to M. luteo-alba, white at the base of the segments, the blades yellow tinged with red, Honeysuckle-scented. From Walter Cobb, Esq , Tunbridge Wells (gr., Mr. J. Howes), (Botanical Certificate).

Fruit Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. R. Parker, Jas. H. Veitch, J. Cheal, W. Poupart, E. Shaw Blaker, A. H. Pearson, W. Pope, Alex. Dean, S. Mortimer, J. W. Farr, Geo. Woodward, C. Herrin, J. W. Bates, A. F. Barron, F. Q. Lane, W. J. Empson, Geo. Wythes, H. Balderson, W. H. Divers, J. Willard, and Robt. Fife.

Messrs. Geo. Bunyard & Co., Maidstone, contributed a collection of 100 dishes of Apples, in such condition as would be commendable at the end of the year—much more so in April. Very few of the handsome fruits showed the least sign of shrivelling, and such sorts as Blenheim Orange, Cox's Orange Pippin, Braddick's Nonpareil, and even earlier-ripening varieties were included. The New Allington Pippin was conspicuous, the fruits of same being plump and very fresh looking. The exhibit was the more interesting from the fact that Messrs. Bunyard displayed excellent illustrations of the interior and exterior of the famous fruit-room, where, at the Allington Nurseries, Maidstone, fruits are so wonderfully well preserved (Silver-gilt Knightian Medal).

Mr. Geo. Wythes, gr. to the Duke of Northumberland, Syon House, Brentford, showed dishes of ripe Figs, Pingo de Mel and St. John, two excellent varieties for early forcing; also capital bunches of Asparagus from the out-of-door beds. A Cultural Commendation was deservedly awarded to the latter.

Two Apples were shown for Certificates, but failed to obtain them on this occasion.

AWARDS.

Tomato Winter Beauty.—This is described as a seedling from Conqueror, a free-setting variety in winter, and an early fruiter. The fruits are of medium size, deep colour, and very little ribbed, except on the lower surface. A large quantity of fruits was shown by Mr. S. Mortimer, Swiss Nurseries, Farnham Royal (Award of Merit).

Onion Ne Plus Ultra.—A large globular Onion, somewhat resembling Ailsa Craig, and said to be a seedling from that popular variety, and Record. It has proved to be a better keeping Onion than Ailsa Craig, and the specimens shown by Mr. Dunbar, The Nurseries, Hemel Hempstead, were sound to a degree (Award of Merit).

Pea, Carter's Early Morn.—A first-rate early and dwarf-growing Marrow-fat Pea, grown under glass. Mr. W. J. Empson, gr. to Mrs. Wingfield, Ampthill House, Ampthill, showed well-filled pods (Award of Merit).

NATIONAL AURICULA & PRIMULA.

April 18.—Most admirers of the Auricula expected this show to be a poor one, and were agreeably surprised to find so good a display. All that could be done had evidently been resorted to, to have the plants sufficiently advanced by a certain date, for the season is a late one everywhere. Immaturity and a certain lack of finish were noticed in many of the trusses, as is always the case when they have to be hastened unduly. The green edges were on the whole rough, although here and there, there were exceptions; the grey edges also required more time; the white edges and a few of the selfs were in good form, and occasionally a pip nearing perfection could be noted.

The Alpine varieties, which always come more quickly into flower, surpassed in development their more stately relatives, the edged flowers and selfs; still, bright and attractive as the alpines are, they were lacking in numbers and finish. Even the Primrose and Polyanthus, usually such leading features at this show, were not so good as usual; the Primroses especially, for only one dozen plants were staged, and those with rough flowers. Not a plant of a double Primrose put in an appearance in the competitive class, the frost having injured them, and the generally cold weather retarded the appearance of such bloom as the frost had spared; but every grower did his best to make the exhibition successful.

Four collections of twelve varieties of *show Auriculas* competed, the 1st prize going to Mr. J. Douglas, Great Bookham, who had James Hannaford and Firefly, green edges; George Rudd, Dinham, and George Lightbody, grey edges; Venus, Acme, Lady Churchill, and Rachel, white edges; Cleopatra, Teresias, and Mrs. Potts, selfs. The green edges were rough; George Lightbody was in good character: though there was good size of truss, finish was wanting. Mr. C. Phillips, Bracknell, Berks, was 2nd, his trusses of bloom generally smaller than those of the preceding collection, but the quality was rather better. He had of green edges, the Rev. F. D. Horner and Mrs. Henwood, the latter the best green edge in the show, having some well-expanded pips; grey edges, Alderman Wisbey, Richard Headley, and George Rudd; white edges, Rachel, Marmion, and Acme; selfs, Mrs. Potts, Miss Barnett, Mrs. Phillips, and Black Bess. Mr. W. Smith, Bishops Stortford, was 3rd.

The best six varieties came from Mr. Phillips: of green edges he had Mrs. Henwood and the Rev. F. D. Horner; grey edge, Geo. Rudd; white edge, Acme; selfs, Mrs. Phillips and Black Bess. Mr. J. Sargeant, Cobham, was 2nd: he had green edges, Abbe Liszt and the Rev. F. D. Horner; grey edge, Rachel; white edge, Acme; and selfs, Ruby (Simonite), a fine deep red, and Mrs. Potts. Mr. Smith, was 3rd, showing a promising green edge, named Shirley Hibberd.

The best four plants were staged by Mr. J. W. Euston, gr. to Mrs. Whitbourne, Great Gearies, Ilford, who had Mont Blanc, grey edge, a striking flower of good substance and form; white edges, Marmion and Acme; and self, Blackbird. 2nd, Mr. A. R. Brown, Edgbaston, Birmingham, who had grey edge George Rudd; white edge, Heather Bell; and selfs, Heroine and Mrs. Potts. Mr. J. T. Bennett-Poë was 3rd. Mr. A. R. Brown had the best two green edges, The Rev. F. D. Horner; and self, Heroine. Mr. Euston came 2nd, with the Rev. F. D. Horner, and Mrs. Potts.

In the classes for single specimens, the leading awards went as follows:—Green edges: 1st, Mr. P. J. Worsley, Clifton, Bristol, with the Rev. F. D. Horner; 2nd, Mr. J. Sargeant, with Abbe Liszt. Grey edges: 1st, Mr. W. Smith, with Rachael; and 2nd with Geo. Rudd. White edges: 1st, Mr. Brown, with Acme; 2nd, Mr. Sargeant, with Heather Bell. Selfs: 1st, Mr. H. Hemnell, with Heroine; 2nd, Mr. C. Phillips, with Mrs. Phillips.

There were three collections of fifty plants, in not less than twenty varieties. To some outsiders it must appear that this class is a kind of refuge for the destitute, in which anything can be put which is not good enough for the classes. Mr. J. Douglas was placed 1st; of green edges, he had the

Rev. F. D. Horner, Rolt's Green (a variety in which the ground colour is red instead of dark), Lancashire Hero, in its green dress, Dr. Hardy, and seedlings; grey edges, George Lightbody, Frank Simonite, George Rudd, and Colonel Champneys; white edges, Acme, Venus, Rachel, and Snowdon Knight; selfs, Heroine, Mrs. Potts, Phyllis, Black Bess, and Ruby. Mr. C. PHILLIPS was placed 2nd, Alpine varieties largely preponderating, and THE GUILDFORD HARDY PLANTS NURSERY COMPANY was 3rd; the best quality appearing to be in this collection, as compared with Mr. Phillips; but the latter had the largest bulk of bloom.

The Alpines, always bright and effective because of their rich colouring, were fewer in number than usual, and not so well finished either. Mr. C. PHILLIPS, who is now our leading raiser of new varieties, was 1st with his own seedlings, having of gold centres—Myra, very fine; Evelyn Phillips, Mrs. J. T. Strange, Lady C. Walsh, Cassandra, a very novel flower, which may be accepted as forming a new break; Mrs. Martin Smith and Saturn, white-centre Perfection and Mrs. F. C. Barnett, these representing the leading varieties. THE GUILDFORD HARDY PLANT NURSERY were 2nd. Dean Hole, A. Maxwell, J. Gilbert, and Gannymede, were the best.

Mr. C. PHILLIPS also took off the 1st prize for six varieties, having Regina, Nigra, Topsy, Cassandra, Mrs. Gorton, and Perfection. Mr. EUSTON was 2nd: Rosy Morn and Colonel Kitchener were his two best.

Mr. A. R. BROWN was 1st with four varieties, staging John Allen, Dr. Knott, Mrs. Gorton, and Mrs. Bartholomews. Mr. P. PURNELL was 2nd.

The best specimen gold centre was Evelyn Phillips, from Mr. C. PHILLIPS; and he was 2nd with the same. Mr. PHILLIPS was 1st and 2nd with a white-centred variety, having Perfection.

It is difficult to describe a *Fancy Auricula*, but anything good in itself that cannot come into the other classes will stand for one. The best twelve came from the GUILDFORD HARDY PLANT NURSERY Co.; Mr. DOUGLAS was 2nd, and Mr. EUSTON 3rd. They were either named varieties or seedlings.

Fancy Polyanthus and Primroses, usually such an extremely attractive feature, were sparsely represented, and by no means up to the average. The March frosts did the plants much harm, and the birds have everywhere seriously damaged the flowers. Mr. DOUGLAS was the only exhibitor in each class, and was awarded 1st prizes. No double Primroses were forthcoming in the class set apart for them.

The collections of species and varieties of Primula is usually an attractive feature, but they fell short of their former quality; we missed the fine examples Mr. Douglas used to show so finely. Two collections of twelve plants were staged, but a plant having been withdrawn from one of them, only one lot competed. It came from Mr. P. PURNELL, and consisted of P. obconica, P. japonica, P. nivea, P. cashmeriana, P. floribunda, P. viscosa, P. rosea, P. Forbesii, P. verticillata sinensis, P. denticulata alba, and two varieties of P. Sieboldi. There were a few good pans in the unplaced collection. Mr. DOUGLAS was the only exhibitor of six species, having P. verticillata sinensis, P. obconica, P. nivea, P. intermedia (?), P. frondosa, and P. Auricula.

Miss JEKYLL, Munden, Godalming, had the best basket of Polyanthus and Primroses, consisting of fine white and yellow varieties; Mr. J. T. BENNETT-POË, was 2nd. Mr. P PURNELL had the 1st prize for a collection of varieties of Primula or Auricula in a box or basket not to exceed 12 superficial feet. The leading species were P. obconica, P. denticulata, P. floribunda, P. marginata, varieties of P. Sieboldi and P. Auricula, &c. These were tastefully arranged, showing the habit of each; the GUILDFORD HARDY PLANT NURSERY Co. came 2nd, with fancy Auriculas, arranged in an oval basket in a bed of moss.

Some classes were set apart for those growers who had never won a prize, but only one exhibitor put in appearance in one class, and his exhibit left much to be desired in the way of improvement.

The revived classes for *gold-laced Polyanthus* brought two collections of three plants. Mr. J. WESTON, Balham, an old grower, was 1st, with Monarch and Mrs. Brownhill, and a seedling; Mr. DOUGLAS came next with seedlings. Mr. WESTON was 1st with one plant, showing Lancashire Hero; Mr. DOUGLAS was 2nd with a seedling.

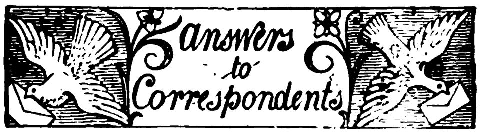
The premier *show Auricula* was Mrs. Henwood, green edge, with seven expanded pips, shown by Mr. C. PHILLIPS; the premier *Alpine*, Myra, a brilliant golden-centred flower, from the same grower; the latter was also awarded a Certificate of Merit. The seedling Alpines were rather poor, compared with previous years; the best varieties are not yet in bloom.

Obituary.

MR. GEO. BOUGHEN, of the Nursery, Sandringham, and forester to H.R.H. The Prince of Wales, died after a short illness, on the 16th inst., from pneumonia, in his 66th year. A man of sterling business habits, courteous and kind to all with whom he came into contact, he was affectionately respected. For over twenty years forester to the Prince, he had seen many changes on the estate, and his opinion was always sought both by the Prince, and his agent Mr. Beck, in regard to the various alterations and improvements that were made. Plain and unassuming in speech and manner, and thoroughly practical in all that appertained to his profession, deceased will be greatly missed by a large circle of friends.

ENQUIRY.

LADY HUME CAMPBELL VIOLET.—Can any reader oblige with information concerning the place of origin and parentage of this Violet?



Answers to Correspondents

BOTANICAL GARDENS: *K.* A list of British and colonial gardens is published in the *Kew Bulletin* each year, and in the *Horticultural Directory* for the current year, published at 12, Mitre Court Chambers, E.C. There are botanical gardens at the capital of most European countries, with the exception of Turkey, Bulgaria, Servia, Roumania, &c.

CORRECTION.—In Flower Garden Calendar, issue of *Gardeners' Chronicle* for April 15, "List of Annuals," read Anagallis for Amaryllis.

CUCUMBER: *C. S. B.* We cannot trace the cause of the malady; the soil seems suitable. Are there any knobs on the roots?

DISHONEST EXHIBITING: *Inexperience.* We should advise a rule being added to the schedule, disqualifying all exhibits not the *boná fide* growth of the person showing. To enable the society to carry out this rule in a satisfactory manner, an inspection of gardens should be made by a small expert committee a few weeks previous to the show. No honest exhibitor would object to this being carried out.

FOUNTAINS: *G. K. P.* It is against our rule to recommend traders. Why not consult our advertisement columns, or those of other journals? With regard to the name of the maker of those at Holland House, a note addressed to Mr. Dixon, the head gardener, might elicit the desired information.

GREEN-FLY ON PLANTS OF MAIDENHAIR FERN: *C. G.* The surest and safest means is the XL-ALL vapour (Richards').

HORTICULTURAL TEACHING: *A. B.* Apply to Mr. Webb. Books alone will not enable you to pass any examination. They must be used only as aids to practical work.

INSECTS: *J. R.* Orthesia insignis; a very troublesome coccid in a few localities in Great Britain. In Ceylon it is a very serious pest, and is known by the name of the "Lantana Bug." Take infested plants from the house, and remove insects with a large dry camel's-hair brush. Repeat this at intervals of eight to ten days for a few weeks, and do not allow the insects to attain their long white tails (ovisacs). A weak soap wash may be found effectual, but the insects are hard to kill. *R. N.*

MILDEW ON ROSES: *W. D.* Roses in some localities seem peculiarly liable to attacks of mildew, and cultivators living in such should take precautions in good time. When the plants are at rest they should be washed with Gishurst Compound soap, at the rate of 3 ounces in a gallon of hot water. During the forcing until flowers appear the plants should be wetted with sulphide of potassium at the rate of half an ounce in 1 gallon of rain-water. If there are no permanent plants in the forcing-house, some flowers-of-sulphur may be sprinkled over a potful of slaking lime before forcing begins in the house.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—J. M.* Festuca ovina, glaucous variety.—*E. C. O. D.* Alchemilla arvensis, a weed, with green flowers.—*F. D.* 1, Forsythia suspensa; 2, Muscari racemosum: 3, Daphne Mezereum.—*A. B.* We cannot undertake to name garden varieties; they are too numerous. 1, a form of N. incomparabilis; 2, one of the Barri section, from incomparabilis; 3, Narcissus bicolor; a form of Pseudo-Narcissus.—*J. E.* Akebia quinata.—*R. C. N.* Iris tuberosa.—*A Reader.* 1, Clianthus puniceus; 2, Gloriosa superba.—*A. B. C.* 1, Bifrenaria Harrisoniæ; 2, Lycaste macrobulbon.—*M.* 1, Dendrobium crassinode Barberianum, a very good variety; 2, D. Pierardi; 3, D. Wardianum, a fine variety; 4, D. devonianum.—*K. P.* 1, Cyrtopodium Andersoni; 2, Bifrenaria Harrisoniæ.—*W. D., Shrewsbury.* 1, Dracæna fragrans; 2, D. amabilis; 3, D. pulcherrima; 4, D. terminalis; 5, D. reginæ; 6, D. marginata.—*R. T.* 1, Richardia Pentlandi; 2, R. Elliottiana; 3, Dendrobium nobile, a very fine large form; 4, D. nobile, good in colour; 5, Croton interruptus.—*W. H. H.* 1 and 2, very pretty forms of Dendrobium nobile.—*G. F. T., Oak.* 4, Euphorbia mellifera.

ODONTOGLOSSUM VUYLSTEKEANUM: *De B. C.* Reichenbach's description is rather vague, but he rendered the matter clear when he wrote (see *Gardeners' Chronicle*, p. 7, vol. xxii., 1884): "As for me, I well know this is no botanic species." Orchidists generally know this fact.

PEACH-LEAVES AND FRUITS INJURED: *J. F.* It is a case of scalding by sun-heat, together with lack of ventilation. This might readily occur in a lean-to house facing due south, in variable April weather. The gardener in charge cannot well be too alert in affording air at this season to forcing-houses; moreover, the leaves being very tender, are more readily injured now than later. There may be defective panes of glass in the roof.

SHELLS IN SOIL: *P. N. F.* The bivalve shells are those of Sphærium corneum, Linné, the commonest one of the so-called "freshwater cockles." I have never heard of fish swallowing the shells, but have no doubt but that the soft parts would prove a most acceptable morsel to the piscine palate. *W. M. W.*

SULPHIDE OF POTASSIUM ON VINES WITH FRUIT SETTING: *Vitis.* It is a ticklish stage at which to employ the sulphide against mildew, and we would advise you to try its effects on a few affected bunches and leaves first, then, if no harm is apparent, proceed further. A suitable strength is ½ oz. to 1 gallon of water. There is no remedy for red spider better than sponging the leaves with warm water.

TOMATOS: *A. R. S.* Your Tomatos are attacked by a fungus. Syringe them with a solution of sulphide of potassium.

VINE-LEAVES DISEASED: *One in Ignorance.* The check in growth is due to the powdery mildew, Oidium Tuckeri. Dry heat and want of ventilation are probably the conditions which have given rise to it. The disease should be checked now, as it will affect the fruit. To check the fungus, use flowers-of-sulphur dusted thinly and evenly over the affected plants, and sprinkle the soil beneath. Or, it may be syringed on, mixed with water. The disease is not difficult to control if the air of the house be looked to and sulphur used. If sulphur is too slow, try a weak sulphide of potassium.

VINES SHANKING, LEAVES THIN AND WARTY: *Vine leaves.* The first is due to unwholesome soil leading to loss of the feeding roots; to the roots being at too great a depth from the surface or to over cropping and wholesale instead of gradual removal of shoots and foliage—which it is in your case we are unable to indicate. Examine the border and the roots, and be especially inquisitive concerning the drainage if the natural soil is retentive. The wartiness and thinness of the leaves are conditions due to lack of ventilation and excess of moisture, the latter being usually the correlative of the former. The obvious remedy is more air, even if a little more fire heat has to be employed and less damping down. We would advise you to employ, in damping down, less chemical manure, soot, and cesspool-stuff, and to rely on clean water. If the vine roots are in a diseased state, the application of manure-water to the border will aggravate matters.

THE
Gardeners' Chronicle
No. 644.—*SATURDAY, APRIL* 29, 1899.

WHEAT AND TULIPS.*

WITH the first of these subjects we need not here concern ourselves; but the second—the Tulip—has great interest for us, and doubtless for many of our readers. The learned professor could scarcely have sought a more interesting exotic plant than the Tulip, nor one the investigation of whose history in Europe was more worthy of his pen. He has evidently spared no pains in acquiring information from ancient writings, MSS., rare books, paintings, and mosaics, and he has arrayed his facts, and marshalled his conclusions in a masterly manner. If hypotheses have to be advanced in order to explain the necessary connection in the lines of advance of the Tulip from East towards the Atlantic, they are extremely modest, and never in any case offend by reason of extravagance.

Commencing with Tulip australis, Link, he combines under it, 1, the smallest-flowered varieties, namely T. Celsiana, D.C., a native of Southern France, the Maritime Alps, and the Tuscan Apennines; T. transtagana, Brotero, of Portugal and Spain; T. fragrans, Munby, from N. Africa; 2, T. alpestris, Jordan, from the Alps of Savoy; 3, T. Grisebachiana, Pantoscek, from the Herzegovina; 4, T. Biebersteiniana, from Southern Russia; 5, T. sylvestris, to which belongs, in consequence of a basal purple patch in the bloom, the strikingly dissimilar Grecian T. Orphanidea, Boissier. Among these forms, T. sylvestris is, he tells us, by far the most widely distributed of all, being found in the whole of Italy, France, Germany, Southern Sweden, and England. According to Levier, it is met with in Attica and Laconia, whilst its allies are, when not transplanted by man, mostly to be found in their native habitats in cultivated land, in vineyards, fields, and parks, and in the vicinity of such places. Only in Greece, Sicily, and the neighbourhood of Montese in the Bolognese Apennines are they now found in the primeval habitats (Levier). Whether they are indigenous to England and North Germany, remarks the author, is doubtful, as De Candolle in 1855, in his *Plantes de Naturalisation à petite distance*, recorded with a mark of interrogation; but as Caruel with certainty showed, in 1879, these Tulips, when found in districts about which there never has been a doubt, as in Tuscany, they form a comparatively recent addition to the flora. Cesalpino (1583) knew of no other habitat for the plant, known then under the name of "Lonchites," than Barga, in the Upper Serchio valley; and de l'Obel (1575) knew of them only in the vicinity of Bologna, and called them Lillionarcissus Bononiensis luteus.

Other writers, Clusius among the number, mention Bologna as the habitat of the Bolognese Tulip, a name that was adopted by all the writers of the seventeenth century. There exists in Florence a manuscript catalogue, most carefully got up by Micheli at the end of the seventeenth century, and from this appears a single habitat of the Bologna Tulip, namely, a spot opposite to the gate of the town; so that it must have been, as it is now, a common plant at Florence and Lucca. Our author thinks that the field Tulip, having become common in Italy at that period, it was an easy matter for the bulbs to find their way to countries north of the Alps, thus throwing doubt on the indigenousness of the plant in Germany, England, and elsewhere. That good grounds exist for such doubts is shown by the fact that in the Upper Rhine Valley the yellow Tulip has a very irregular distribution. In Baden this species grows sparingly in a few places on the flanks of the Black Forest, and at Heidelberg, but it is entirely missing from the flora of Freiburg; whilst in Alsace it is much more abundant, and is detested by the Vine-growers of the Colmar district as an indestructible weed. It is found in the Vine-covered hills of Mülhausen, and in Lower Alsace in many places, as was noted by Kirschleger. In Heidelberg this species was observed in 1782; but in Upper Alsace, however, the first discovery was made in 1794, according to a written notice in the Leipzig University Library, by Mappus, which Hermann says was mentioned by Kirschleger. It is noted there "odorata est. In quibusdam vineis inter Niedermorschwehr et Ingersheim adeo frequens est, ut floris tempore solum flavedine lacteum sit. Ut Hyacinthus botryoides mala herba, Bartholdy und 'Miror Hallerum' dubitare indigenam esse. Miror Mappum qui Alsatiam superiorem frequentius adiisæ videtur non habere. Copiose crescit ad Colmariam, in den Rebstücken auf dem Türckheimer Berge gegen dem Katzenthal, hinter Ingersheim, ubi *Holtz* amicus filii detexit, 1794."

From this passage it would seem that the species was, at that time, unknown in Lower Alsace, whilst to-day it is found in the immediate vicinity of Strasburg, at Kolbshain plentifully, also at Oberehnheim and Mittelbergheim. In Niedermorschwhir it is so abundant in the vineyards that these are yellow with the blossoms. In the neighbouring Switzerland, it was at that period scarcely known, otherwise Haller, 1768, as quoted by Herman, would not have said "non credo veram esse civem et si passim in pratis circa urbem reperitur. Cum tamen Linnæus inter indigenas enumerat non visum est patriæ hoc ornamentum negare. In prato plano et regione urbis, in altem Berg." In Wurtemberg it is not ascertained for certain that the species exists, although Ulm is mentioned by Martens and Kemmler, 1865, as a habitat. *Leopold's Flora*, of this city, 1728, does not include it.

The plant is entirely missing to-day from Bavaria, and in *Franconia*, Volkamerus, 1700, says that "Tulipa boloniensis lutea in hortis." In the vicinity of Leipzig and Halle, the older authors mention it as being only a garden plant. In Saxony and Silesia it is not found in a state of Nature, but only as a garden escape. In Austria the plant rarely occurs; Monte Maggiore, near Fiume, is named by Huss, 1797, and a few other sites.

Linnæus was made by Haller to say that he believed T. sylvestris to be a native plant, but the exact opposite was the case, as he says in the second edition of *Flora Suecica*, 1755, that it was a recent garden escape. Strange to say, Fries perpetuated Haller's new translation in his *Flora Scania*, 1835, p. 170. The old French *Floras* confuse the true Tulipa sylvestris with T. Celsiana, a native of Southern France, and for the purpose of the author they cannot be taken into account. No mention is made of the species by Vaillant, 1723, or by Dalibard, 1749; and Bulliardi, much later, without comment, terms it a wild Tulip.

In England, the species occur on chalk soil in Norfolk and Suffolk; and Hooker, 1870, says it is "possibly wild." Smith also, *Flora Britannica*, 1800-1804, declares it to be indigenous; but Hudson, *Flora Anglica*, 1762, does not mention it. It would therefore appear that Tulipa sylvestris is not indigenous in Germany, France, Sweden, and England, and that its distribution took place in the course of the second half of the 18th century. It is characteristic that the spread of the plant did not occur gradually northward, like Senecio vernalis, or westward like Puccinia Malvacearum, but rather suddenly everywhere.

This sudden appearance was simply due to the fact, that distribution took place from numerous centres, the botanical and private gardens in the countries mentioned, by exchanges and sales long before the plant became wild generally. Even in Italy T. sylvestris was certainly much cultivated in gardens.

If this should seem remarkable to us, for the slight fragrance of the bloom could scarcely have been the inducement to its cultivation, we must remember that the Tulip belonged to the fashionable flowers of those times, and everyone endeavoured to secure the finest and most complete collection of them, from which certainly Bononiensis lutea would scarcely be omitted.

Whilst it is easy to trace the time and mode of distribution of the species from Bologna, it is not so easy to account for its first appearance there, which must have occurred in remote ages. That the species is not indigenous to Bologna appears from the writings of Mattei, in which it is stated that the plant was found in cultivated land, namely in Acacia and Gleditschia woods, and never in virgin land. In this matter he pays no regard to the statements of others, that it is found in the Bologna Apennines by Montese, a certainly primæval habitat, also in the Apuan and higher Apennines where Tulipa Celsiana is commonly found. Mattei believed in the Tulipa Celsiana having descended from the higher mountains to the lower foot-hills, and the result of changes in the climatic conditions originated the Bologna Tulip, its appearance occurring about Bologna in historical times.

This opinion of Mattei finds several supporters and opponents; among the latter Krelage, who carried out experiments in Holland with T. Celsiana, but with negative results, seeing that the plant had been cultivated in that country from the time of Clusius, and remained essentially constant, and never became like T. sylvestris; and the author gives a number of reasons why that should so be.

(To be continued.)

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT GUNNERSBURY HOUSE.

THOSE who were fortunate enough to see the magnificent group of Dendrobium formosum giganteum, staged by Mr. Jas. Hudson, gardener to Messrs. de Rothschild, at the Royal Horticultural Society, on October 11, 1898, greatly admired the specimens, though many doubted if such success could be maintained in the case of such a reputedly bad doer. Several of the plants shown had been in Mr. Hudson's care for seven or eight years, although with these exceptions the plants were imported two years ago. The group consisted of thirty-four plants, bearing together about 700 large pure white flowers with yellow discs to the labellum, the shade of yellow varying in the different specimens.

---

* *Weizen und Tulpe und deren Geschichte*, von H. Grafen zu Solms-Laubach, Professor der Botanik an der Universität, Strasburg. Leipzig: Verlag von Arthur Felix, 1899.

A recent visit to Gunnersbury House has shown that specimens are not only sustaining their vigour, but are increasing in size and in the number of their young growths, which are now pushing strongly in the warm house in which they are suspended. Further evidence that the treatment the plants are given is salutary may be seen in the several young seedlings raised from the seeds brought over on the roots of the importations, and some of which are approaching maturity.

Many cultivators utterly fail to get this fine nigro-hirsute Dendrobium to thrive for any length of time, and some help may be obtained from briefly considering Mr. Hudson's method. Of course, with this, as with many other Orchids, something depends on getting suitable places in which they can grow and rest. That being secured, Mr. Hudson holds that if the warm-growing season and the cooler dry resting season be observed, no difficulty should arise. But as a means of preventing stagnant moisture at all seasons, he attaches much importance to his plan of using good-sized pieces of virgin-cork beneath and areund the plants, which with the cork, are fixed with sphagnum-moss in the baskets in the usual way.

A general collection of Orchids is not attempted at Gunnersbury House, only batches of showy things; but even the most difficult, such as Vanda cœrulea, seem to thrive remarkably well.

The many ranges of fruit-houses are well-cropped, especially the vineries, Strawberry-houses, and Orchard-houses. Some of the stone fruits in pots are thinly cropped, the fogs having destroyed the flowers and newly-set fruits.

The new Bamboo-garden, and the bog-garden beside the lake, with the new coloured Water-Lilies, will soon form fine features in the pleasure-grounds. *J. O'B.*

VANDA TERES AT GUNNERSBURY PARK.

Those who are disposed to think that Vanda teres is a shy-flowering species, should have seen it at Gunnersbury Park at the end of the third week in April. It was then grandly in bloom at the west end of a lean-to stove. This house faces south, and a line of plants in a long box occupies the end of the house close to the glass, which is fully exposed to the sun after 11 o'clock in the day. A passage-way down by the end of the central pit divides the front line of plants from one which has its box resting on the brick side of the pit. The two lines of plants, one behind the other, make up a length of from 9 to 10 feet each, and between them they had about 160 expanded blossoms, and wonderfully fine ones, too. It was a glorious sight, I say was, because three days after the flowers were all cut for sending to Newmarket. The plants are growing in a mixture formed of clean crocks, charcoal, and sphagnum. Mr. Reynolds holds that the position occupied by the plants has a most important bearing on their well-being. At the end of May or the beginning of June, the plants are cut clean through just above the surface, the boxes are re-soiled, and the severed plants, which have ample roots, planted in the fresh soil. Moisture is reduced as the days shorten, but augmented as spring approaches. This glorious species can scarcely be seen under better conditions than at Gunnersbury Park. One or two plants show more distinct and richer markings than those of the type, and will probably be known as the Gunnersbury Park variety. *Four.*

ONCIDIUM WARSCEWICZII.

This pretty Oncidium, discovered by Warscewicz on the Chiriqui Mountain at 10,000 feet altitude, never seems to have been imported in quantity, though, in 1870, Messrs. Veitch & Sons obtained from Costa Rica a few good plants. Since then it has appeared occasionally, but never in sufficient numbers to bring it into prominence. It is characterised by large bracts at the base of the flowers, which are about 1½ inch in width, and of an uniform bright yellow colour, the blade of the lip extended on a long claw or isthmus. The species is also known as O. bifrons. A fine inflorescence has come to hand from the collection of Mrs. Ida Brandt, Riesbach, Zurich.

MAXILLARIA TURNERI.

This pretty and fragrant Orchid appeared many years ago in the then famed collection of Mr. Turner, and for many years the only plants of it in gardens were pieces taken from the original plant, even if the whole of the stock now in cultivation is not so. It affords a proof that Orchids need not degenerate under cultivation. A fine plant is now in flower with Walter Cobb, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes). Each leading growth produces a number of flowers. These have narrow segments, the bases of which are white, the upper portions yellow tinged with reddish-brown, especially on the reverse side, and exhaling a pleasant odour of the Honeysuckle. Some regard it as a variety of M. luteo-alba, but both the plant by its brownish tint, and the plant and flowers, have other characters which render it distinct from that species.

ODONTOGLOSSUM ADRIANÆ "LADY WIGAN."

A few years ago there appeared in an importation made by Messrs. Linden, of Brussels, a series of very pretty Odontoglossums, which had the form of O. Hunnewellianum to a great degree, and the new arrivals were supposed to be the result of a natural cross between O. Hunnewellianum and O. crispum, and forms of them were figured in the *Lindenia* under the name of O. Adrianæ. Later, several forms of it appeared with cultivators in England, one of the prettiest being the variety named above and here illustrated (fig. 95), shown by Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), at the meeting of the Royal Horticultural Society, on April 18, when the Orchid Committee gave it an Award of Merit. The neatly shaped flowers were cream-white spotted with brown, the crest being bright yellow.

DENDROBIUM × CYBELE, OAKWOOD VARIETY.

The original form of this graceful cross between D. nobile and D. Wardianum was raised some years ago by Messrs. J. Veitch & Sons. The present variety (fig. 96, p. 259), was raised by Norman C. Cookson, Esq., Oakwood, Wylam, Northumberland (gr., Mr. William Murray), the form of D. nobile used being D. nobile Burfordiense, which, it will be remembered, gave a case of trilabellia, as in D. n. Cooksoni, except that the labelloid markings in imitation of the lip appears in the lateral sepals instead of in the petals, as in D. n. Cooksoni, and in most other cases of irregular peloria in Orchids. The batch raised by Mr. Cookson displayed great variety, but the plants were tolerably constant in the markings on the lower sepals, although they differed in tint. The flowers of this charming hybrid are white, tinged and tipped with bright rose colour; the disc is purplish-crimson on an orange-coloured ground.

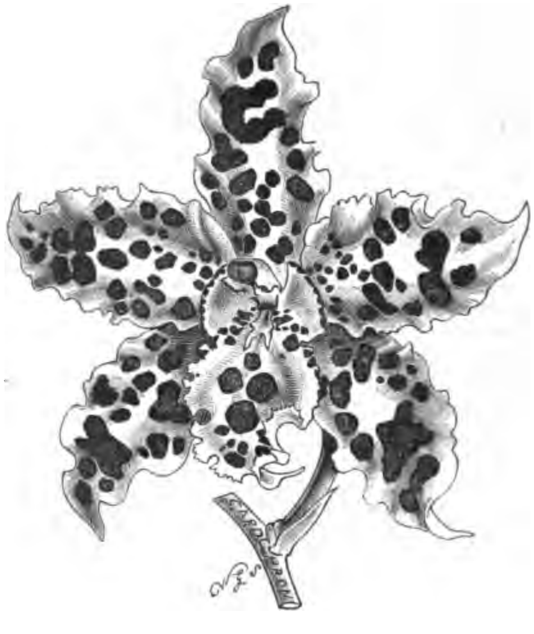

FIG. 95.—ODONTOGLOSSUM ADRIANÆ "LADY WIGAN."

THE BULB GARDEN.

HYMENOCALLIS.

THE species of Hymenocallis proper (excluding Ismene) possess white fragrant flowers, which are sessile, or nearly so, and have green filaments and styles. The species are so much alike that the nomenclature of these plants is in a confused state in many gardens. All require, with perhaps one exception, stove treatment, and copious supplies of water when growing. H. tubiflora and H. littoralis, the latter a warm greenhouse plant, grow best with the pots partially submerged. They must be shaded from strong sunshine when growing, and are benefited by syringing on bright days. Manure-water, preferably from cow-houses, will help them considerably; soot and lime-water sprinkled on the pathways will intensify the rich green of the leaves. They enjoy a fairly ample root-run of sandy loam, mixed with one quarter of its bulk of well-rotted leaf-mould; stronger growing plants, such as H. speciosa, H. littoralis, and H. caribæa, may have an addition in dried cow-manure broken into small nodules. When growth is completed, it is advisable to rest them in a pit or house having a temperature of 55° to 60°, decreasing the amount of water at the same time. As they are not deciduous unless rendered so, they must not be allowed to become quite dry, or the leaves will suffer. Over-dried bulbs take some time starting into growth again, and in this state they are susceptible to the attacks of the bulb-mite.

One of the most distinct is H. tubiflora, with thin ovate lanceolate leaves a foot or more long, 5 inches broad at the middle, with a short petiole. The peduncle is short and slender, and bears an umbel of ten or more erect flowers, with long slender tubes and drooping linear segments 4 inches long, and a small, not toothed, occasionally plicate staminal cup. This species is now becoming common in cultivation, owing to the demand for its long tubular flowers in a cut state.

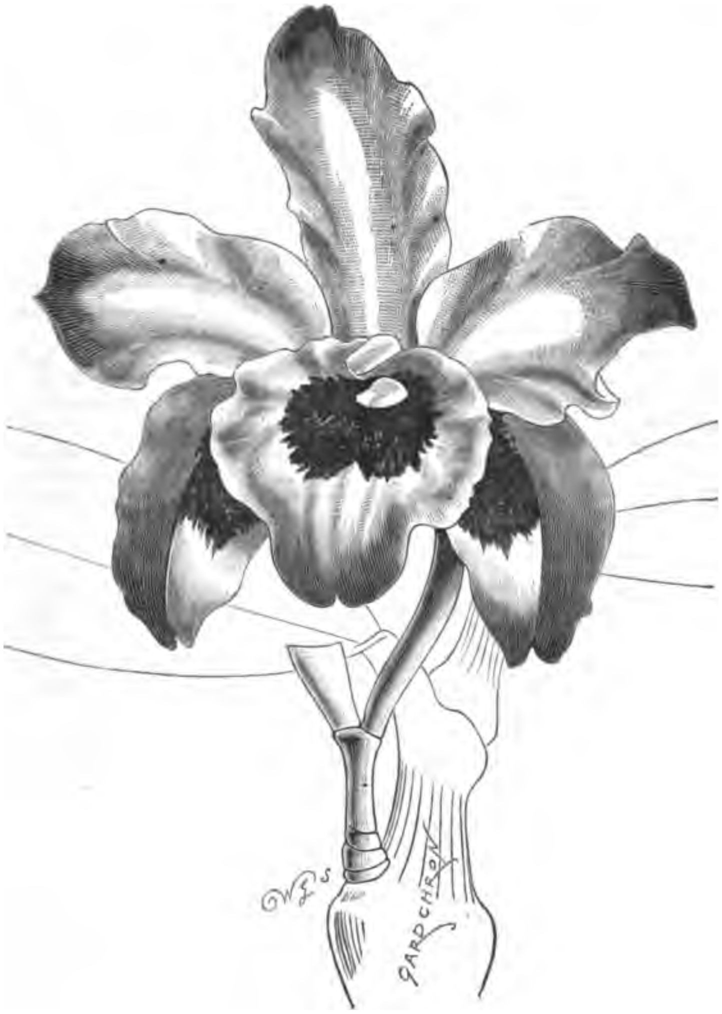

Fig. 96.—Dendrobium Cybele. (See p. 258.)

H. undulata.—This species has leaves similar in shape to those of H. tubiflora, but with a longer and more slender petiole. The peduncle is stout, 1 foot or more high, with an umbel of eight or more flowers, each 6 inches long and wide, with a slightly curved tube, narrow segments, a toothed staminal cup, and red-tinted filaments. This species is largely grown on the Continent under the name of Pancratium undulatum. It is a native of Venezuela.

H. speciosa.—This is a plant which varies a good deal in the shape of the leaves, as in H. caribæa, H. Moritziana, and H. ovata to H. eucharidifolia. The leaves of the type are tough, usually twelve in number, each 1½ to 2 feet long, 6 inches broad, with a short winged petiole. The flowers range in cultivated forms from 6 to 12 inches in diameter and length, and consist of a stout tube, segments up to half-an-inch in width, and a toothed staminal cup 1 to 2 inches across. They usually appear in the autumn.

H. caribæa.—This plant is mostly confused with H. speciosa, which it much resembles. It differs in having leaves upwards of 2 feet long, 3 inches broad, thin in substance, and the flowers more closely arranged on the top of the peduncle, and furnished with shorter tubes. Its variety patens has a long slender peduncle, with longer and thinner flowers.

H. expansa has narrower and longer leaves and flowers than in H. caribæa, otherwise there is no apparent difference.

H. Moritziana produces leaves with the blade 1 foot long, 6 inches wide, with a long stout petiole, much resembling those of Eucharis grandiflora. The flowers, produced in early spring, are thinner and more lax than in H. speciosa, otherwise there is no difference in cultivated specimens.

H. eucharidifolia.—This is a compact plant, with leaves 8 or more inches long and broad, with a very short-winged petiole, the leaves being alternately arranged around a thickened stem composed of the sheathing petioles. The peduncle is a foot in length, bearing a dozen flowers, which do not materially differ from those of H. speciosa, or H. Moritziana. It is a free-flowering plant, taking up but little room; the flowers it produces are quite as good as those of more bulky species. It comes from Venezuela.

H. ovata.—This species resembles H. speciosa under cultivation, differing only in having smaller, almost sessile, ovate leaves a foot long, shorter flowers and peduncle. A plant I have, under the name of H. filamentosa, is either a form of this species or H. speciosa; it is distinct only in the unusual length of the filaments. The flowers of typical H. ovata are very lax and poor, but, under high cultivation, the flowers and leafage greatly improve.

H. littoralis.—This species may be accepted as the type to which H. disticha, H. tenuiflora, and H. senegambica, are allied. It is extremely variable in leaf and flower. The leaves of the type are 2½ feet long, strap-shaped, or narrowly lanceolate, sessile, up to 2 inches wide, glabrous-green in colour, and tough in texture. The flowers average ten to an umbel, and consists of a tube half-a-foot long, ending in recurved, and occasionally twisted segments, 4 inches long, adnate to the base of the staminal cup. This cup is an inch in length and width, toothed, and occasionally plicate when the flower first opens. It may be grown successfully in a warm greenhouse, but should not be over-fed with manure, or the flowers will come with fasciated filaments and distorted perianth-tube. *H. tenuiflora* is a species from New Granada with slimmer flowers, otherwise resembling H. littoralis, or some of its many forms.

H. senegambica.—A species from West Africa, which, though geographically removed from H. littoralis, a New World species, differs only in having a wider staminal cup, which becomes almost rotate as the flower ages. It requires stove-house temperature to do it well.

H. Harrisiana is a plant of small growth, with leaves 1 foot long, a short slender peduncle, bearing three flowers with slender tubes and narrow segments, the staminal cup being small, and curiously plicate. It is a native of Mexico, and a comparatively recent introduction into gardens, though known as far back as 1838.

H. lacera has narrow, sword-shaped leaves, similar to those of H. littoralis; the flowers are much shorter than in that species, with a spreading, almost rotate staminal cup. It is a native of the Southern States, and may be grown successfully in the warm greenhouse. Poor forms of this species are hardly worth cultivating, when so many richer-flowered species are available.

H. macrostephana.—This plant is considered to be a hybrid between H. speciosa and H. (Ismene) calathina. The leaves are 3 feet long, 3 inches broad at the middle, sessile, with a sheathing base. The flowers are produced in an umbel of eight, and consist of a short tube of a greenish-white colour, white segments, 3 inches long, half an inch wide, and a wide funnel-shaped, partially-dilated staminal cup, the free ends of the filaments being incurved—a characteristic of Ismene. It requires the same treatment as given to H. speciosa. *G. B. M.*

SPONTANEOUS HYBRIDS OF HARDY PLANTS.

(*Continued from p. 210.*)

Campanulas.—No spontaneous hybrids of Campanula have ever shown themselves in Edge garden, except in what I call the C. rotundifolia section, including C. rhomboidalis. These seem to cross freely together, and it is easy in my garden to pick out a series in which all the so-called species would seem to be concurrent. C. rotundifolia itself, as a native species, is so remarkably variable in stature, in shape and size of flower, in breadth and form of leaf, and these distinct varieties so often prevail in well marked areas, that botanists are tempted to make several native species; but Godron remarks in his *Flora of France* that the whole section is such a little chaos, that he acquiesces in the conclusions of his predecessors, though hardly any two of them formed the same conclusions! However, all these crosses are unfortunately fertile, though with anything approaching to isolation parents reproduce themselves with constancy, as they do in many other varieties of species amongst hardy plants.

There are five or six well-established hybrids of Campanula known in gardens, C. Van Houttei (including its pale form, C. Burghalti), C. Hendersoni, C. haylodgensis, and two or three forms known as G. F. Wilson. In *Index Kewensis*, the first three are printed as species of unknown habitat, notwithstanding the prevalent opinion that C. Van Houttei and C. Hendersoni are hybrids raised, either artificially or by accident, by the nurserymen whose names they bear. C. Hendersoni is almost certainly C. carpatica × C. pyramidalis; C. haylodgensis and the G. F. Wilson's are known to have been raised by artificial crossing about thirty years ago by the late Mr. Anderson Henry, of Hay Lodge, in Mid Lothian. The former was said to be C. carpatica × C. pusilla, and the others, C. carpatica × C. pulla. Indeed, their pendulous flowers suggest C. pulla, and there has lately been distributed from Mr. Archer Hind's garden in Devonshire, a similar spontaneous hybrid known to be a seedling of C. pulla. Having grown these hybrids for many years, and having, year after year, looked for seed on them in vain, I have come to the conclusion that they are all barren, though more than once in seed catalogues of botanic gardens I have seen seed of C. Van Houttei offered, but I have never been able to get it, and should be glad to know if anyone has ever raised it.

Before leaving Campanula, I mention an obscure and mysterious form, C. planiflora (Lam.) syn. C. nitida (Aiton). It is wrongly referred in the *Index Kewensis* to C. pyramidalis, with which it has nothing in common. As Gray rightly classes it under C. persicifolia, but says it has never been found wild anywhere, much less near Hudson's Bay, as former botanists asserted. Though there is a double form, I have never heard of seed of it; it may possibly be a hybrid, but I believe it to be a persistently stunted form of C. persicifolia. Anyhow, a plant of it has come in my garden amongst seedlings of C. persicifolia.

Poppies.

Hybrids amongst Papaver are rare, and I have found them invariably barren, though they may develop fruit well-developed and sound. The many varieties of P. orientale and P. bracteatum are not properly hybrids, as these two belong to one species; but the most interesting hybrid Poppy I have, came originally from Mr. Carrington Ley's garden, near Maidstone, and is P. rupifragum × P. orientale. The same plant of P. rupifragum growing there by the side of P. orientale has produced several successive crops of hybrid seed. I have twice raised perhaps a hundred plants from seed he sent me gathered from it, and they are perfectly constant, being very good garden plants, flowering abundantly in summer and autumn, ripening fruit, but never a seed. Mr. Carrington Ley's Poppy is not the only instance I have known of the same plant producing only hybrid seed year after year. I have in vain tried to produce the same hybrid artificially in Edge garden. The only other hybrid Poppy I have seen, which came here spontaneously, was P. caucasicum × P. Rhœas, two very distinct species. The intermediate characters were unmistakeable. The few plants which came were, of course, annual. I have recently sent a note to the *Gardeners' Chronicle* concerning P. commutatum (E. Boissier, syn. P. umbrosum, Hort.), which has for many years grown here, and ripened seed, mixed in the same bed with P. Rhœas. The seed of P. umbrosum is blue, and can at once be distinguished from that of P. Rhœas, and so can the seedlings at every stage, and I have never seen an intermediate form, yet the *Kew Index* treats the two as specifically the same. I have seen in seed catalogues "Hybrid Poppies" of particular colour and markings, offered, said to be between P. Rhœas and P. somniferum. If such a hybrid exists, which I doubt, the offspring certainly would not be constant.

Saxifragas.

A short notice should be taken of hybrid Saxifragas. Several of our best winter-flowering forms are known to be hybrids, as S. apiculata, from which I have never got seed, and two very choice Saxifrages, bearing the name of Mr. Boyd, their raiser. One, with pale yellow flowers, is presumably S. Burseriana × S. aretioides; the other, with white flowers, probably S. Burseriana × S Rocheliana. Both are sparingly fertile, and I have raised seedlings from them all reverting towards S. Burseriana, and inferior to their parents. S. Burseriana is a variable species, and it is not always easy to say whether seedlings of it are hybrids or typical. I have at least one hybrid which I refer to it, crossed spontaneously with S. Rocheliana. The flowers are large, pure white, and nearly sessile; the foliage and habit resemble the yellow S. Boydi, but the flowers are produced very sparingly. A hybrid named S. Macnabiana, like a compact and elegant form of S. Cotyledon, comes nearly true from seed, a rare character in hybrids. S. longifolia from home seed shows many signs of being hybridised. In its native home it mixes freely with S. Aizoon, and this is probably the commonest foreign pollen parent, but I find most of the incrusted Saxifragas so uncertain from garden seed that I cannot say anything definite about their hybrids. As far as I have observed, these are mostly more or less fertile. *C. Wolley Dod, Edge Hall, Malpas.*

(To be continued.)

CONIFERS.*

(Concluded from p. 227.)

Grafting.—All Conifers, if not too resinous, may be grafted; but, however successful this operation may be, grafted plants are never so successful as seedlings, because they rarely make perfect "leaders," and symmetry is thus sacrificed; this is most marked in Pines and Firs.

In grafting, the selection of the "stock" becomes an important item, for before we can "graft," we must have something to graft on, and this "something" must be suitable, or the grafts will not "take." The best stock for Thuyas is the American Arbor-vitæ (T. occidentalis); T. orientalis, however, refuses to unite with this. Thuya gigantea is equally good. For Junipers, Juniperus virginiana is best; and for the Cupressus family, use C. sempervirens. Larix europæa is a good stock for Taxodium, and is said to be so for the Dammara Pine, and for the Deodar Cedar. Cedrus atlantica forms a good stock for the Deodar.

The weeping forms of Larch are best increased by inarching in the open ground on the common Larch (Larix europæa). For true Pines, use Pinus sylvestris, P. Strobus, P. excelsa, or Abies pectinata. In all cases seedlings make the best stocks. With Pines, a caution is necessary, for if potted in small pots for the purpose of inside grafting, the roots often become cramped and assume a corkscrew form, which always stunts the trees in their after development. It is advisable to pot only those seedlings as stocks which possess short and fibrous roots, and not to twist any of these roots (the more easily to get them into the pots), and thus initiate the "corkscrew" twist.

This potting-up of the various stocks should be done in autumn, and placed in cold frames. In March, take these stocks, which will have become established by this time, and select scions for them. These scions should consist of "leaders" in the Abietineæ and Araucaria, and strong laterals in Cupressineæ and Taxus. Various methods of grafting may be adopted. Tongue-grafting is a good general practice; but crown, saddle, and splice-grafting may also be practised with success. Terminal grafting is, perhaps, the best method in Pinus, and, in fact, in Abietineæ generally. It is said that terminal grafting of herbaceous shoots may be successfully performed in a close case in spring. Having adapted the scion to the stock in one or other of the above ways, bind with Raffia, and smear the union with "clay-paste." Then place them under the stage in a warm pit for a couple of days; at the end of this time examine the union again, and, if necessary, add more clay, and plunge them in fibre in a close pit (temperature 70° F.). Water very sparingly, and occasionally damp overhead with a fine-rosed can, and shade from sun's rays. At the end of three weeks or a month the union should be complete. Take them out and gradually harden them off, and finally plant them out in the "nursery," where staking, watering, &c., must receive every attention.

Pseudo-larix Kæmpfera is best propagated by grafting scions on moderately thick pieces of its own root, well furnished with fibres. This is a method which deserves more general practice. Ginkgo biloba is diœcious, and grafting serves to unite the two sexes on one tree. Seedlings, or cuttings, of the type (G. biloba) form suitable stocks. Cleft-grafting in March in the open, or veneer-grafting in August under glass, are both equally successful.

Cuttings.

Generally speaking, these should be selected from laterals, when the sap is in full motion (August or early September). They should consist of last year's branchlets, 4 to 6 inches in length, with a "heel." Place them in shallow boxes, or beds of sandy soil, under a north wall, or in a cold frame, and shade. Better still, and always with the more tender species, place them in pots and plunge in bottom-heat of 70° F. In the latter case, with the hardy species, as soon as roots show, harden off and plant out in cold frame. Their after-treatment is the same as that of seedlings. In Retinospora (Cupressus), Araucaria, and Agathis, the main leader must be taken. With the last two the leader may be "ringed" and "mossed" (like Dracæna), and afterwards removed, but I question if this be really advantageous, for I once saw one treated in this way and stood in a temperature of 65° F. for eighteen months, and then it had only "callused." Cutting them off and plunging in brisk heat is, I think, preferable. Of course, the Chili Pine requires cool treatment. I know of one which was rooted in the open (true, it was three years in rooting), but it is now making a nice plant (4 feet high). After the leader has been removed, numerous lateral outgrowths form, and these when large enough make good cuttings. Araucaria Cunninghami has been raised from root-cuttings, and I think this might prove a very remunerative method of propagation. Roots two or three inches long, and half to three-quarters of an inch thick, placed in bottom heat of 65° to 70° F., root in six to eight weeks.

Layering.

This is easily performed by bending, slitting, and pegging down a desired shoot. It answers very well for Taxus and Cupressus. *E. H. Wilson.*

THE FERNERY.

CHOICE ADIANTUMS.

From among the great number of beautiful species, it is difficult to make a limited selection, seeing that all are more or less of merit when well cultivated, and the modern mode of treatment certainly brings out the characteristics of the plants to much advantage. In place of peat as a potting-soil, heavy shading on the houses, and much moisture, nearly all the species will be found to succeed better if potted in a compost consisting largely of good fibrous loam, leaf-mould that has been well cleansed from worms, &c.; some well-dried stable-manure (I like to get it free from straw, &c., and dry it on the hotwater-pipes), some sharp sand, and good drainage. In such a compost there are few Adiantums which will not succeed. I should add, that the compost should be used in a rough state, having a great objection to the use of a sieve, as it takes away the best portion of the compost.

In potting Adiantums, care should be taken that the roots are not crowded up together. Where the roots are much matted together the lower portion may be cut away, for it is from the surface that the new and most vital roots are produced. I do not like to disturb them while the plants are dormant, but after they have started into active growth, at which period they take hold of the new soil quickly. Many of those with spreading rhizomes may be divided according to the number or size of plants required; if only a small portion of the outside rhizomes are taken off with care, young healthy plants may be established which will soon overtake the original, especially in the size of the fronds.

---

* Extracts from a paper read before the Mutual Improvement Society of the Royal Gardens, Kew, by Mr. E. H. Wilson. The Hooker Prize was awarded to this essay.

After re-potting or dividing, they require a little shading and a fairly moist atmosphere, but water should be afforded very sparingly at the roots until they have made a good start. After the plants are well established, and the pots filled with roots, most of the Adiantums will take up a good deal of moisture. While over-watering is one of the greatest evils in Fern culture, the other extreme is also fatal. With attention to watering, most of the Adiantums may be grown fully exposed to the sun, and they will then make fronds of great substance; besides which, in many varieties the young fronds will have a bright rosy tint, which is quite lost under heavy shading. There are some which, under any treatment, will retain the deep green, the varieties of the Capillus-veneris type being examples of this; and I find those which never show any colour in the young fronds like a little more shade than those with the rosy-tinted fronds.

In making a selection, I hardly need say that A. Farleyense should always be included; the variety alcicorne, which has deeply-cut, irregular pinnules, though not an improvement on the type, is an interesting form. I can find no record of its origin, but I believe Messrs. R. Smith & Co., of Worcester, were the first to have it, and this must be upwards of fifteen years ago. A. curvatum is a very distinct and beautiful species, with ample, spreading fronds of a rich deep green, forming a nice contrast to those with the bright tints. It is a native of Central America, and requires stove treatment; it is one of those which require shading from the direct rays of the sun, but will not succeed under the shade of other plants. A. trapeziforme is a more vigorous-growing species, and may be grown into a large specimen; this does not show any colour in the fronds, but will thrive well in a sunny position. A. Lemonianum is a very distinct species, with ample, drooping fronds; the large pinnules have long, slender stipes. A. Seemani somewhat resembles the above, but it does not make such large fronds, and is of a deep green; they both require stove treatment and some care, in order to succeed well with them. A. cardiochlæna (polyphyllum): this is another which makes a fine specimen, the fronds are of a pale soft green, with a greyish shade, and when exposed to the sun the young fronds have a beautiful mauve tint. It is more suited for larger specimens, as it does not develop to its full beauty until it gets into a 6 or 8-inch pot, when it will grow from 2 to 3 feet high. A. macrophyllum: of those with bright-tinted fronds this is the best known, and as it is readily raised from spores it is grown extensively for market from tiny plants in thumb pots to large specimens, it is equally beautiful. It requires stove treatment, and unless well exposed to the light and sun is very tender; under any circumstances it cannot be recommended for winter use, but during the summer it will stand fairly well unless exposed to a dry atmosphere. A. macrophyllum bipinnatum: this has tallish fronds, and the lower portion bipinnate. I have never known this to be raised from spores, though what appear to be fertile fronds are plentiful; it may be increased by divisions. A. fovearum: the young fronds of this species have a bright, almost crimson tint, changing to a pale soft green. This may be raised from spores, but is rather a delicate Fern; it somewhat resembles the beautiful A. tetraphyllum gracile, which I am afraid is now nearly extinct in this country. A. tenerum and A. scutum: two useful Ferns, differ in that the first named has fronds which, when young, are of a crimson tint, while in the latter they are of a pale hue; when much exposed they may have a bronzy-brown tint. A. Lathomi has more drooping fronds, of a soft pale green. A. Mariesii is one of the best varieties of Capillus-veneris, the rich, deep green fronds stand erect on stiff, almost black stipes. A. imbricatum is also worthy of note, having drooping fronds, with large, deeply-cut pinnules. I must leave out the numerous varieties of the cuneatum type; also many others which are equally worthy of culture. I could from memory extend these notes to include upwards of 100 species and varieties, all of which have some merit, but even if space would admit there are not many who could find room for such a large number of one genus. *H. A.*

NEW INVENTION.

CAUSLEY'S FOLDING PROTECTORS.

THIS folding protector, which has just been patented and put on the market by Mr. C. Causley, 25, Downs Park Road, West Hackney, London, seems to be an article of much ingenuity and completeness for the protection of seeds and plants in their early stage of growth. One important feature it possesses is that, when not in use, it can be folded into a space of 7 inches in thickness, and packed away in a small compass, a matter of great advantage for carriage to a distance, or for export. In this frame or protector there are several features, which are shown by accompanying diagram (fig. 97), viz., ventilation, which can be adjusted at will by means of two ventilators in the top of each frame, giving perfect control over the ventilation. The method of affording water is quite novel, and it is effected by simply pouring water from an ordinary watering-pot into a receptacle fitted into the centre of the top of the frame; this receptacle, when full, throws the water in a fine shower to the full extent of the space under the frame, and as it empties gradually affords water to the centre, thus water is applied to the whole space covered by the frame. In fixing the glass no putty is used in any part, the panes of glass slipping into strong zinc frames, so that if broken they can be easily replaced.

Each frame is complete in itself. If the ends are removed a number of frames can be linked together, so as to form a continuous row, an end being inserted at each extremity, thus a long row of plants, such as early Peas, Tomatos, Strawberry-plants, &c., may be protected practically by one protector, affording free ventilation the whole length; or an end can be inserted at any desired part, dividing the row. Wire screens are fitted to each side of the frames to protect the glass, and when the frames get too hot, the panes of glass can be removed from the zinc frames, the wire screens being left to protect the young plants from injury. Growth in these protectors is very rapid, owing to a great degree of warmth generated in the frames, and the moisture arising from the earth.

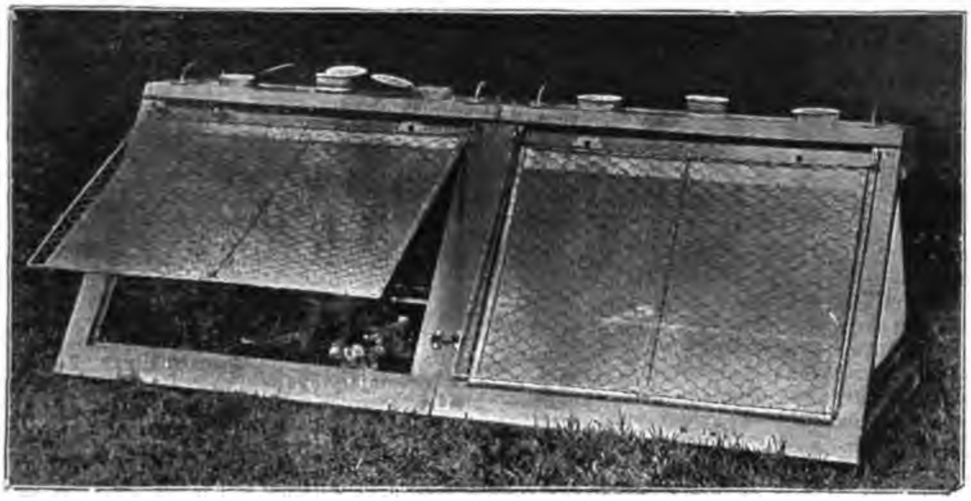

FIG. 97.—CAUSLEY'S FOLDING PROTECTORS FOR SEEDS AND PLANTS.

FLORISTS' FLOWERS.

CHRYSANTHEMUMS.

THE plants are making rapid progress. In some few instances the leaves may show a deficiency of chlorophyll or colouring matter. This is due to one of three causes, the most likely one being an excess of water at the roots, which causes a check to growth. Chrysanthemums are moisture-loving plants, especially during the summer, when the pots are full of roots, and growth is free and vigorous; but in the spring, before these conditions are attained, the plants may be easily injured by an excess of moisture at the roots. Cold draughts, when the plants are first placed in the frames, may also cause the foliage to become pale.

Some varieties are more delicate than others, and continue pale in colour throughout their growth. The ingredients of the soil may have an effect in the same direction, especially if lime be present in excess. In any case there is a remedy. Less water at the roots will be the best corrective for the cause first named. Greater care in ventilating the frames is an obvious remedy for draughts of cold air.

If an addition of charcoal and wood-ashes be made to the compost, it will help to make the compost more suitable in the case of heavy loam. The use of sulphate of iron is a ready means of restoring colour to the leaves. Dissolve half an ounce of the substance in two gallons of water, and give an application once each week.

Continue to repot the plants as they require more root-room. From 3½-inch pots, plants should be removed to pots 5½ inches in diameter. The compost should consist of three parts fibrous-loam, one part of horse-manure in a half decayed condition; and a quantity of wood-ashes, sand, and charcoal, may be added according to the character of the loam employed. To 1 bushel of the prepared compost add 2 lb. of Thomson's vine and plant manure, or other good fertiliser. Drain the pots with care, and pot firmly. Place the plants for the present in a cold frame, facing south. A thick bed of coal-ashes will keep the base of the pots from becoming too damp, and prevent the ingress of worms.

After potting the plants keep the frame rather closer for a few days, until new growth has commenced. Keep a sharp look-out for insect pests, of which green and black-fly are the worst; dustings of tobacco-powder will rid the plants of these. *E. Molyneux.*

SCALE INSECTS.

THE Orthezia is one of, if not the most resistent of all scale-bugs towards insecticides. An insecticide that will kill Orthezia can be almost guaranteed against any scale pest. It is remarkable that the half-grown insects will often survive treatment that has successfully destroyed the younger and older individuals.

In the case of isolated trees attacked by this pest, the gas treatment is really the most effective and complete. This consists in covering the tree with a tent or sheet of some closely-woven material, beneath which hydrocyanic-acid gas is generated. The deadly gas will penetrate to every part of the tree and reach every single insect. I have recently ascertained by experiment that an extra strength of the gas with a shorter exposure (than usually prescribed) is the most certainly fatal to the insects, and the least injurious to the plants. The gas treatment, however, though really very simple, requires considerable care in application, and is subject to certain dangers. It cannot therefore be recommended for general use without previous demonstration by a trained operator.

Spraying is the next best measure. But however thoroughly this work may be done, a certain proportion of the insects is bound to escape, and the process must be repeated at intervals until the pest has finally disappeared. I have found that mixtures, of which soap is the principal component, are more efficacious against Orthezia than any other form of insecticide. Besides killing the insect, the soapy-matter blocks the aperture of the ovisac, and so prevents the emergence of the young larvæ. Kerosine-soap emulsion is a useful and inexpensive mixture, but requires careful preparation. The formula is:—Kerosine, 2 gallons, common soap, ½ lb.; water, 1 gallon.

Dissolve the soap in water heated to boiling. Add the kerosine to the hot mixture, and churn till it forms a thick cream on cooling. The churning is the most important part of the process. If this is not done thoroughly, the oil separates out on cooling, and will not then mix with water. A properly compounded emulsion may be subsequently diluted to any extent. The churning may be effected either by stirring vigorously with a bunch of twigs, or the liquid may be repeatedly drawn up and expelled through a garden syringe. To test the mixture, put a drop on to a piece of glass. If it adheres without separating into oil globules, the process is complete. For application, dilute with nine or ten times the bulk of water. Kerosine emulsion should not be applied during sunshine, or serious injury to the plants may result. *Circular, Royal Botanic Garden, Ceylon.*

CAMELLIAS.

"R. C." (see p. 236) will find that the best time to repot Camellias is immediately the plants have flowered, and before the trees commence to grow. Small trees require to be repotted about once in three years, and the larger specimens only when the soil has become impoverished, or soddened by careless watering. When the latter is the case, the pots should be broken, as the plants drawn from them are apt to be pulled from the roots. Do not give them too large a shift; 1½ inch will be sufficient room between the ball and the pot. Pick with a pointed stick all the old soil without damaging the roots; then place some hollow crocks at the bottom of the pot, covering this with a layer of small broken brick and pieces of turf, which will prevent the soil from being washed into the drainage. In potting, use a compost of three parts fibrous peat, one part loamy soil, and sufficient broken charcoal and silver-sand to keep the whole porous. This should be added gradually round the ball, and made firm with a potting-stick, finishing off by leaving the surface 2 inches below the rim of the pot. Pruning is essential to keep the plants in a good shape, and to obtain strong growths and flowering buds. The shoots should be cut back to about six leaves, or fewer, according to the strength of the plants, and as soon as they have finished flowering. Upright-growing varieties, when young, should have the shoots drawn down with string, fastened to sticks wired across the pot. This will cause the back buds to push, and form growths near the stem. If the surface-soil becomes stagnant, it should be removed, and a top-dressing of peat and silver-sand mixed with either Standen's manure, or bone-meal, will be found beneficial. After potting, and when the plants are commencing to grow, raise the temperature of the house from 65° to 70°, and keep a humid atmosphere by syringing between the pots and overhead with tepid soft-water. When growth is completed, admit gradually more air to the house, and when the plants are sufficiently hardened-off, place them outside on a cool border, where they will be shaded from the sun. Any trees too large for pot-culture may be planted out in a border or bed; but of the many varieties we grow here, I have only found four that were not suitable for this purpose, viz., Reticulata, Bealei rosea, Mrs. Abbey Wilder, and Eximia. These varieties, if planted against a back-wall in the large conservatory and kept tied in, succeed well. Trees that produce imbricated flowers, are most favoured. These are not so stiff and formal, and as a rule the trees are of better habit. When limited to space, the following selection of varieties will be found a good one:—C. fimbriata alba, white; Sacco-i-novæ, pink; Leeana superba, salmon-red; Holfordiana anemone, flowered pink; Reine des Beautés, delicate rose; Chandleri, red; imbricata, red and white; Madame Lebois, bright rose; Leon Lequay, rich crimson; Reine des Fleurs, vermilion-red; Queen of Roses, delicate rose; Lady Hume's blush, flesh-colour; Princess Bacchicocchi, rich velvety-carmine; and Donckelaari, semi-double rich crimson. *A. Chapman, Westonbirt.*

BELGIUM.

L'HORTICULTURE INTERNATIONALE.

IN the houses, the Orchids are now beginning to flower abundantly. I lately noted among them Oncidium sarcodes, with petals and lip very much spotted; Miltonia vexillaria, with two inflorescences from one bulb, one with large handsome flowers of a deep rosy-purple tint, the other with insignificant blossoms. There are many good varieties of Cattleya Mendeli and Cymbidium eburneum; masses of Vanda tricolor and suavis are opening their fragrant flowers, and there is a fine V. gigantea with two splendid floral stems. One house is entirely filled with Cypripedium Lawrenceanum, with fine and well-coloured flowers; another with C. bellatulum coming into bloom; one curious variety bore many pale rose-coloured spots on the blossom. Odontoglossum Wilckeanum and O. luteo-purpureum are very fine; among the former are the varieties O. picturatum, O. chrysanthum, O. flexeolum, and O. pallens; in the latter group are O. nigrum, O. tigrinum, O. formosum exquisitum, O. regale, O. superbum, O. splendens, O. nigrescens, O. spectrum, and O. conspicuum. There is a good plant of O. mulus superbum; one of O. Rossii majus rubescens, bright lilac-rose, and with the petals and lip of elegant form, the edges waved, and fluted, and veined with darker rose; O. cirrosum is coming freely into flower. Some examples of Warscewiczella are remarkable for the deep colour of the segments and lip. *Correspondent.*

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD,
Wrotham Park, Barnet.

Peas Growing in Pots.—Peas standing in pots need careful applications of water, and tolerably free ventilation in mild weather. Many varieties of Peas may be successfully grown in pots, but the plants must not be hard forced, the proper night temperature ranging from 50° to 55°, and that of the day 10° to 15° higher, with the higher figure in bright weather. The plants should stand where the fullest sun reaches them. When the plants are in bloom, do not syringe so freely as at other times, but as soon as the pods are formed, dew the plants over twice daily in bright sunny weather, and let the temperature run up by partly or quite closing the ventilators early in the afternoon, admitting air at a later hour, which need not be excluded if the weather is mild. The soil must not be allowed to get dry, more especially when the plants are in bloom; and to assist the pods to fill, afford soot-water and liquid-manure alternately with tepid clear water. Plants growing in frames should have the lights drawn off in bright weather; this will be better than tilting the lights at the back and front.

Potatos.—The frames should be freely ventilated on favourable occasions by day, and water afforded, not wetting the tops. Let the frames be protected against cold by means of mats laid on at 6 A.M., and uncover at 8 A.M., or earlier if it be warm. Before earthing-up the stems, afford water, if such be needed. Potatos growing in pots should not be kept very moist, and when the tubers are grown of suitable size for use, the pots may be stood in any out-of-the-way place, say under the stages of the house, till required.

Asparagus.—If young plants are not yet planted, no time should be lost in getting the operation finished. The most suitable time to plant Asparagus is when the young growth appears. Let the plants be placed in trenches just deep enough to allow the crown to be covered with an inch of soil, and broad enough to allow the roots to be spread out without crowding. Seed, if not already sown, should be got into the ground. The produce of beds in bearing should be gathered daily, and in order to avert injury by frost, covering materials should be laid handy to put on when needed.

Globe Artichokes.—The suckers may now be dug up, and fresh beds made, by planting clumps of three or five in well-prepared ground. With suitable attention to watering and manuring, these plants will afford good usable heads in the autumn.

Onions for Pickling.—Sow seed broadcast on firm, poor soil; as if sown in the usual manner on good land the bulbs grow too large.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to the Right Hon. W. H. LONG,
Rood Ashton, Trowbridge.

Pine-apples.—Affording water and syringing the plants will demand frequent attention now that they are in active growth, and the sun is getting more powerful daily. Closing-time, however, is when syringing has the most beneficial effect; but in the morning the damping of the walls and floor is sufficient, this being repeated during the day more or less often in accordance with the weather. Ventilation should be afforded early in the day if it be bright, thus preventing an undue rise of the internal warmth, and imparting vigour and sturdiness to the plants.

Fruiting Plants, providing the roots have filled the pots, are much benefited by the application of weak liquid manure. Suckers and recently-potted plants should, however, receive only clear water. If the plunging material in any of the divisions needs removal or additional tan or leaves, choose a dull day at this season for doing the work, placing the plants meanwhile close together in one part of the house or pit, or in an adjacent house or heated pit. Great care must be taken after making these additions, that the heat is not so great as to burn the roots, or cause plants to start to fruit that are not of the proper age. At the first, it is safer not to plunge the pots to their full depth, and should the test sticks or the plunging thermometer show a heat of more than 90° in the fruiting-house or of 80° to 82° in the succession and sucker-pits, loosen the pots in the bed, or lift them and put a couple of handfuls of tan, &c., at the bottom of the hole, returning the plant to it, and finally plunging it when the heat has receded to a safe point. If a bed becomes very hot, besides lifting the pots, bore holes all over with a stout stake, in order to allow the heat to escape. In replacing, do not permit crowding, but let each plant have sufficient space for half a year's growth; keep all plants pretty close to the glass, and be sure that there is a clear run for drip on the rafters, or much harm will be done by the soddening of the soil in the pots. Small zinc troughs 1 inch wide are very useful in dripping houses in carrying off the condensing moisture. Take suckers whenever any good strong ones can be obtained, but do not let more than two develop on any plant. Close the house in the afternoon as early as is safe, syringing freely among the plants on bright days, but omitting this when the weather is cold or cloudy. Avoid the overhead damping of plants in bloom, or those on which fruit has changed colour. If more fruits are ripening than can be consumed, the plants with ripe fruits may be removed to a cool room. The heat in the pipes must be regulated in accordance with the weather, keeping it low during sunshine, and allowing an increase of warmth in time to meet the declining solar warmth before it recedes too much.

Early Vinery.—Where stoning of the berries is passed, progress will be rapid, demanding close attention to the application of water to the inside borders, more especially if these are shallow or narrow, and the loam they consist of is of a light nature. Once a month may suffice for borders made of heavy soil, when others may need water once a week. This is a point of importance, and can only be determined by the gardener. Red-spider, which often puts in an appearance in vineries at this season, can be kept in check by painting the pipes with sublimated sulphur, which is to be preferred to the flowers-of-sulphur because more effectual and safer. Syringing of the Vines, if practised, should be discontinued as soon as colouring commences, and a "chink" of air at night assists materially in giving a perfect finish. If red-spider is already established, sponging of the foliage is the best remedy; but prevention is the better course, and can be obtained by judicious ventilation and watering, and the use of sulphur on the hot-water pipes.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Hardy Ferns.—The majority of these plants revel when planted on a rockery, provided the right position and the proper sort of soil be used. Where suitable stone is not procurable, burrs from the brick-kilns form excellent substitutes, and pockets can be readily formed from them. The best position for a fernery is one with a northern aspect, or in a shady dell, with plenty of subdued light. The Scolopendriums and a few others will grow in the deep shade of trees and rocks. Ferns may be cultivated on level ground and on banks, but the beautiful forms do not show themselves to such perfection as when seen against some rugged rockwork; neither can they be treated separately in such positions as regards the amount of moisture and the kind of soil that suits them.

Soils and other Materials.—Peat, loam, leaf-mould, broken sandstone, and limestone, and soft bricks, are the chief requirements of most Ferns.

Planting and Arrangement.—In arranging the plants in a fernery it is advisable to mix some of the evergreen varieties with the deciduous ones, which will take off the bareness in the winter common to ferneries, when these are planted solely with the latter. Among evergreen species are Asplenium Trichomanes, A. Adiantum nigrum, A. angustifolium, A. fontanum, A. germanicum, A. lanceolatum, A. Ruta muraria (wall-rue or spleen-wort), which all require small nooks in the higher and drier portion of the rock-work. Polypodium vulgare and its distinct varieties, crenatum, cambricum, semilacerum, omnilacerum, pulcherrimum, grandiceps, and cristatum, form fine masses when planted in stiff retentive loam. Blechnum spicant (Hard Fern) is in many districts not easy to establish, but where it succeeds it is a noble Fern; Polystichum aculeatum and P. angulare are by far the easiest and handsomest to cultivate, growing from spores freely, and soon forming graceful specimens. P. angulare grandiceps, proliferum, and Wollastoni, and numerous other varieties of these, are distinct and beautiful. Scolopendrium vulgare, and its many varieties or sports, are refreshing and cool to look upon. They prefer a strong loam, but they will grow well in brashy rock and sandstone *débris* provided moisture is not lacking. Lastræa filix-mas, L. cristata, L. dilatata and varieties, are almost evergreen, and may be planted in the more exposed positions of the rockery. Among the deciduous Ferns, Athyrium filix-fœmina (the Lady Fern) is the most fragile, and should be planted in a shady, sheltered position, and where there is much dampness. The numberless varieties of these are very distinct, both in the form of the fronds and in the dark and light green colour of the stems. Cystopteris fragilis, C. f. Dickiena, C. f. bulbifera, and C. f. montana, when once planted, spread among the crevices of the rockery; Osmunda regalis, O. r. cristata, O. cinnamomea, O. interrupta, O. spectabilis, should be planted at the base of the rockery where the conditions are very moist. The same site suiting Onoclea sensibilis, a fern that delights in the shade must have plenty of room for its rhizomes to spread. Polystichum Lonchitis and P. L. munitum, a Californian species, are perfectly hardy and very distinct; Cyrtomium falcatum and C. f. Fortunei are both hardy in these gardens, planted in the driest position in the rockery, and soon grow into large specimens.

Treatment.—Ferns that have been established some years can be kept in health by annual top-dressings of loam, leaf-mould, and peat afforded before the fronds throw up, and after a heavy rainfall. In very dry places or in soils that part with their moisture quickly, a few flat pieces of stone placed on the surface will prevent a good deal of evaporation of moisture.

The Rock Garden.—Rockeries that have been formed near to the edges of ornamental water, or in deep ravines, are the more effective if planted with shrubs of as bold a type as the rockery will permit, such as flowering Berberis, Spiræas, clumps of green-leaved and variegated Ivies, Cotoneasters, Roses, Daphnes, Ericas, Rubus, &c., also Yuccas, Ferns, giant Grasses, Bamboos, Megaseas, and other plants that have striking outlines. These, in time, will be apt to overgrow the space allotted to them, and should then be carefully cut back during spring; but preserving in them a rugged outline, so as to secure a natural appearance.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

The Strawberry.—The time has arrived when the beds should be afforded a mulch of long stable litter or other not readily decaying materials, for the purpose of keeping the fruits clean. Before the litter is placed round the plants, the ground should be hoed, and weeds removed by hand from among the crowns. If stable-litter be used, it should be the straw only; this must be brought close up around the plants, and spread over the alleys as well. By applying the mulching now, the manurial properties will be washed down to the roots by the rain, and the straw made sweet and clean before the fruits appear. If no rain should fall soon afterwards, water ought to be applied by hand or with a hose, before the sun and air have dissipated the ammonia, &c. Manure-water may also be poured in the alleys so as to strengthen the growth, especially when the beds are two or three years old. If stable litter be not obtainable, dry bracken may be substituted, and for keeping the fruits clean it answers the purpose very well. At Dropmore, bracken only is used, a thin mulch of horse-droppings with a slight mixture of peat-litter as brought from the stables, and turned over and broken up finely, being afforded the beds early in the spring. Owing to the unseasonable weather, but few flower-trusses have pushed up on the earliest varieties, and an early season can scarcely be looked for.

Planting-out forced Strawberry Plants.—The later batches of plants are excellent for planting-out purposes, producing heavy crops the next year, and after this date they require but little hardening off before being planted. For producing a few dishes of fruits in autumn, too, the variety Vicomtesse H. de Thury is often very valuable. When planting, the root-mass should be reduced in size by shaking away some of the outer soil, and the soil in the pots should be in a moderately moist condition. Plant at 2 feet apart each way in ground that has been manured and deeply dug, and make the land firm by trampling around the plants.

General Remarks.—The weather, at the time of writing, is cold and overcast, and not favourable to the blossoming of fruits of any sort, rendering the use of coverings still advisable.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Odontoglossum crispum.—Where many plants are grown, some of them will be in a condition rendering repotting or surfacing necessary before the weather becomes warm, summer warmth having an injurious action to the plants which are not re-established. Plants from which the flower-spikes have recently been removed, should be afforded only as much water as will avert the shrivelling of the pseudo-bulbs, otherwise there will be premature growth.

Anguloas.—These species of tropical Orchids, sometimes called Cradle Orchids from the swinging movement a slight touch imparts to the flower, are not favourites with Orchid-cultivators, though when well grown and arranged with other species of strong growth they are showy plants. The flower-scapes are now appearing at the base of the young growths, and these will shortly be followed by a batch of new roots. In order that these may afford nutriment to the plant, fresh materials should now be applied to the surface after picking out as much as possible of the old. The materials should consist of turfy-peat, loam, and sphagnum-moss in about equal proportions, sprinkling in as the work of filling proceeds some very small crocks. Any plant which has become too large for the pot, &c., should be carefully turned out at this season, a little of the surface-soil removed and placed in a larger pot, providing there are no old back bulbs to remove, for when this is possible, probably the plant will only require a pot of the same diameter as before. Let the space around the ball be filled in with crocks to within 2½ inches of the rim, cover these with rough material, and finish off with the mixed compost. Anguloas should be kept in an intermediate house, and be very sparingly afforded water till the roots grow. Later in the season if the undersides of the leaves are syringed on favourable occasions, red-spider will not increase in number. Lycaste plana Barringtoniæ, L. mesochlæna, L. Cobbiana, L. costata, and the wonderful green-flowered L. Mooreana, thrive under like conditions and treatment.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Salvias.—Of the varieties of these plants which are suitable for pot-culture, S. splendens, S. splendens var. Bruanti, S. coccinea, S. Bethelli, and S. patens, are those commonly grown, and of these again the first and last-named are probably the most useful and effective. S. splendens is extremely floriferous, producing dense spikes of the most vivid scarlet flowers, whilst S. patens rivals the alpine Gentians in possessing flowers of the deepest shade of blue. Salvias are generally propagated from cuttings, and young shoots inserted now in 4½-inch pots filled with sandy soil, and placed in a warm house, or plunged in a hot-bed, will root readily, and may then be potted off singly into small pots, and placed in a pit with an intermediate temperature for a few days to become established, afterwards being gradually hardened off and placed in a cold pit. When well-rooted they should be shifted into 5-inch or 6-inch pots. Salvia splendens is subject to the attacks of red-spider, and should therefore be freely syringed during dry weather. When all danger of frost is passed Salvias may be stood in the open air, on a bed of coal-ashes.

Miscellaneous.—Place a few plants of Euphorbia (Poinsettia) pulcherrima in the stove to provide cuttings for an early batch of plants, but, as later-struck plants are best for the main supply, keep the old plants at rest for two or three weeks longer. Continue to put in cuttings of Begonia Gloire de Sceaux and Gloire de Lorraine for late flowering, also other winter-blooming species and varieties. Choice varieties of tuberous-rooted Begonias may also be increased by cuttings when the young shoots have attained the length of 4 or 5 inches. Begonia socotrana should be kept quite dry at the root while resting, and may be placed in an intermediate temperature. Ipomœas and other climbing annuals should be prevented from becoming entangled by timely attention to staking them, and by staging them wide apart. Small dead seedling Larch form a very suitable support for Ipomœa Quamoclit, or, failing this, a few sprays of Birch about 18 inches in length may be placed in each pot.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR MAY.

TUESDAY,	MAY 2	Royal Horticultural Society's Committees. Scottish Horticultural Society, Meeting.
THURSDAY,	MAY 4	—Linnean Society, Meeting.
FRIDAY,	MAY 5	Royal Botanic Society, Lecture National Auricula Society (Northern Division): Exhibition in Coal Exchange, Manchester.
TUESDAY,	MAY 9	Royal Horticultural Society of Ireland, Meeting.
FRIDAY,	MAY 12	—Royal Botanic Society, Lecture.
SATURDAY,	MAY 13	—Royal Botanic Society, Meeting.
TUESDAY,	MAY 16	Royal Horticultural Society's Committees. National Rose Society's Committee Meeting.
WEDNESDAY,	MAY 17	Imperial Russian Gardeners' Association: International Exhibition at St. Petersburgh (10 days).
FRIDAY,	MAY 19	Manchester Royal Botanical Society's Whitsuntide Exhibition, continuing until May 25. Royal Botanic Society, Lecture.
SATURDAY,	MAY 20	Cheltenham Horticultural Society's Exhibition (2 days).
MONDAY,	MAY 22	—Bank Holiday.
WEDNESDAY,	MAY 24	Linnean Society, Anniversary Meeting. Bath and West and Southern Counties Show at Exeter (5 days). York Florists' Exhibition of Tulips, &c.
FRIDAY,	MAY 26	—Royal Botanic Society, Lecture.
SATURDAY,	MAY 27	—Royal Botanic Society, Meeting.
WEDNESDAY,	MAY 31	Annual Exhibition of the Royal Horticultural Society, in the Gardens of the Inner Temple, London (3 days).

SALES FOR THE ENSUING WEEK.

WEDNESDAY,	MAY 3	Lilies, Greenhouse Plants, Begonias, Gladioli, &c., at Protheroe & Morris' Rooms.
FRIDAY,	MAY 5	Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period April 16 to April 22, 1899. Height above sea-level 24 feet.

Remarks.—The week has been characterised by dull weather, and very cold mornings.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—51 5°.

Actual Temperatures :—

London.—*April* 26 (12 P.M.): Max. 56°; Min. 45°.

Provinces.—*April* 26 (6 P.M.): Max. 54°, Salisbury; Min. 47°, Tynemouth.

Apple-tree Roots and Stocks. Few subjects connected with hardy fruits are of more interest and importance than that of the influence of stocks, and the study of the root-system of the trees. There is much more to be learnt in this matter, and it is well worth a thorough investigation, though many difficulties are in the way of a satisfactory inquiry. In the first place, it is almost impossible to secure a number of trees or stocks in a uniform and comparable condition. Even in dealing with one kind of stock raised either from seed or layers, there are always considerable visible differences in the vigour of stem and root growth, and internal variations may still more often occur which are not evident. It is rare that much time can be devoted in nurseries or gardens to the selection of stocks of equal strength. The weakest, or deformed, may be discarded; but amongst those retained, though healthy, and quite satisfactory for ordinary purposes, differences in the amount of roots or strength of stem equal to 100 per cent. can be commonly found on close examination.

Consequently, with the greatest care that can be adopted, some variations are always observable in the growth and behaviour of trees worked on the same stocks under similar conditions. How far such characters may prove constant, or merely temporary, experience in each case can only determine; for it is impossible, with our present knowledge, to state a rule that is equally applicable to all. Attempts have been frequently made to generalise on the influence of stocks, but as they are necessarily founded on incomplete evidence, they are repeatedly nullified by fresh observations.

About the year 1875 a collection of stocks for Apples was formed at Chiswick; they were obtained from the most reliable sources, were carefully compared, and the eighteen supposed distinct sorts were practically reduced to the following: — French Paradise (Pommier du Paradis), English Paradise, English Nonsuch, English Broad-leaved, Doucin, Pommier Franc (Free Stock, presumably a seedling), Dutch Paradise, and the Crab. The whole eighteen were, however, kept under their respective names, and all were grafted with Blenheim Orange. In the third year from grafting the trees showed flowers; and for four years, namely, from 1878 to 1882, the blossoms were counted, and the numbers recorded. Considerable differences were observed, but the disparity is quite as great between the results from the stocks that were considered identical as from those admitted to be distinct, though attention is not specially called to this point in the record. For instance, the French Paradise, as obtained from an English nursery, and Pommier du Paradis from a French establishment, were found to be identical and true to name, yet the tree on the former produced in the five years one hundred and ninety-two flowers, while that on the latter bore four hundred and sixty flowers. Again, two stocks obtained from old trees in the Chiswick Gardens, regarded as "identical, and probably the English Paradise," bore in the one case two hundred and thirty-five flowers, and in the other none at all in the whole period.

In a third case, two stocks received as Pommier du Paradis and English Paradise from the same source, were determined to be "identical and distinct from either the true French or English Paradise," yet the former only produced forty-six flowers, and the latter had one hundred and ten. The nearest approach to each other in flower results in the case of stocks bracketed as identical were afforded by the Pommier Doucin, and Doucin from different sources; the numbers being for the former five hundred and four, and for the latter three hundred and seven, still a material disparity. Very little fruit was produced during the period named, and the growth also did not afford any uniform indication of the stock effects, except that the strongest were the trees on the Crab and Free stocks. These trees have been examined many times, but no definite conclusions could be drawn from their subsequent behaviour.

At the present time an even more interesting series of facts may be noted at Chiswick in connection with this subject. About fifty varieties of Apples were worked on a dozen presumably distinct stocks, and in the first year it was thought marked differences were being developed; but further experience has brought out some strange results, for, in many instances, the trees are as nearly alike as it is possible for trees to be. Without going into full details, the following varieties are especially noteworthy, the trees being in bush or pyramidal form, and some are now of considerable size. A dozen good trees of Waltham Abbey Seedling on as many stocks show very little difference in growth. Bramley's Seedling, on seven stocks, are all materially alike, except one on the French Paradise, which is dwarfer, and more compact. All the others show the free, open, vigorous habit of the variety. Mère de Ménage on seven stocks are nearly exactly alike, and as far as appearance of the growth is concerned, no one could suppose there was any difference in the roots.

Twelve well-developed trees of Claygate Pearmain, or as many stocks, afford a remarkable instance, for they are as uniform as possible.

The same number of Lane's Prince Albert closely resemble each other, and all show the peculiar loose habit of the variety. Six Cox's Orange Pippin, and seven Yellow Ingestre, are examples of the same kind.

In the course of lifting many of these trees, Mr. S. T. Wright assures us that the differences in the roots were no more marked than in the growth; and the same observation applies to the quantity of the fruit, while the individual fruits are not affected in size, colour, or quality.

If the whole history of these trees were not known, it would be thought that some mistake had been made; but such an idea cannot be entertained here, for the original experiments were commenced under the superintendence of Mr. A. F. Barron, and every care has undoubtedly been taken to ensure accuracy. We know that considerable differences are visible in the various stocks at the beginning of their career, and it is evident that certain varieties can gradually overcome all these peculiarities, asserting their own characteristics, the influence extending to the root system. That some varieties of Apples possess a greater vitality than others a moderate experience in pruning, grafting, and budding will demonstrate if a close observation is kept. There is a greater power of forming fresh tissue, of healing wounds, and of effecting a perfect union with the stocks upon which they are worked. A good example of what is referred to here is afforded by Bramley's Seedling, which forms new tissue very rapidly, and it is for this reason that it has been recommended for grafting on beheaded trees in the process of restoring old orchards. It is surprising how large a surface becomes covered and "healed" by the new cell-growth from healthy scions of this Apple.

Another variety which possesses the same power in almost an equal degree, though a much less vigorous grower, is Potts' Seedling, and this also exerts a powerful influence upon the roots. Lord Grosvenor, Red Astrachan, Cockle's Pippin, Cox's Pomona, and Gascoigne's Scarlet Seedling, may be taken as similar examples, but many more could be named; and the power is not confined to the strongest growers either, for there are several which produce only slender wood but which are yet vitally strong.

Not only do such varieties assert their special characters to a great extent independently of the stock upon which they are growing, provided other conditions are on an equal basis, but they affect the root system of the stock both as regards mode of growth and texture. This applies more particularly to stocks that have been raised from layers. When we are dealing with seedling stocks, whatever they may be, the differences between themselves are very much greater, and the tap-root exerts an influence for a considerable time, even though it be shortened, and its downward tendency checked by artificial means. The root-systems of the two types of stocks are essentially different at starting, but even their characters are lost in time, and when "worked" with vigorous varieties. After handling hundreds of trees of various ages it would have been easy to select some on seedling stocks that might have been taken for layers, and *vice versâ*, so far as could have been judged by the proportion of fibrous roots and the direction of the main divisions. The whole subject, however, is full of interest, and there is ample room for investigation.

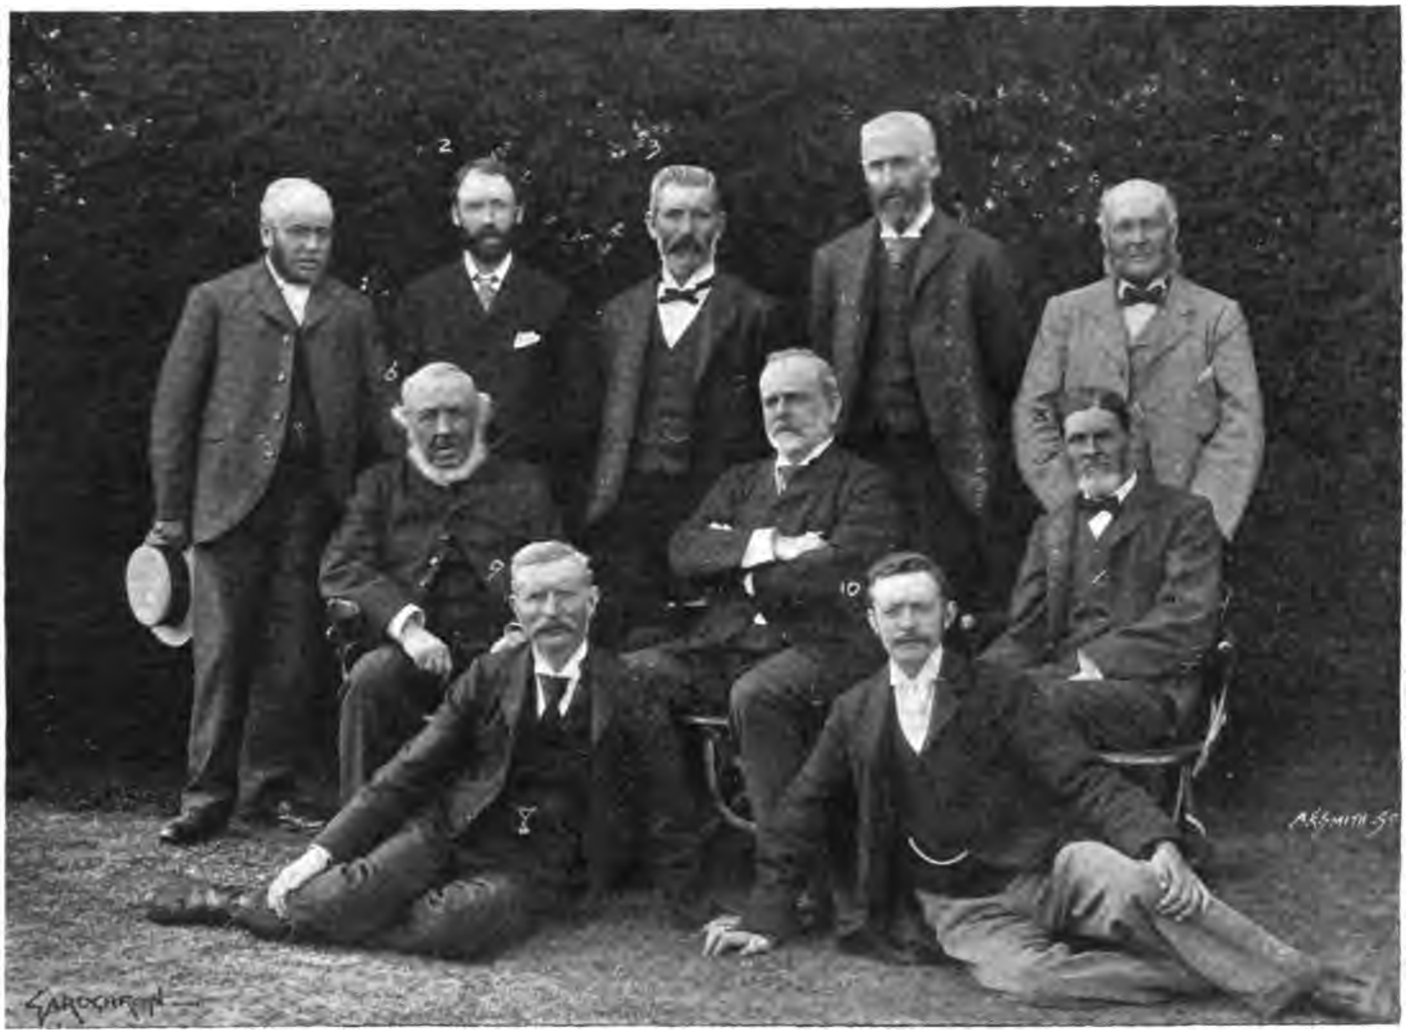

Fig. 98.—THE STAFF IN HER MAJESTY'S GARDENS AT WINDSOR, 1899.

1, W. Barker; 2, J. Brown; 3, T. Edwards; 4, J. Dunn; 5, J. Chinnell; 6, C. Marr; 7, Owen Thomas (*Head Gardener*) 8, G. Hampton; 9, J. Jack; 10, J. Green.

Foremen in the Royal Gardens, Windsor.—The particulars of the services of the foremen at Windsor furnish evidence of long garden service under one employer, which can scarcely be equalled by any other private garden establishment, and helps to demonstrate the comfortable conditions under which the work of Her Majesty's private gardens are conducted. Each foreman is well paid, well housed, and secure of a fair pension, if he lives to become too old for work. The nationalities of the foremen are fairly divided, six being English, three being Scotch, one being Irish, and one Welsh. Marr has held the position of kitchen-garden foreman for the long and uninterrupted period of fifty-two years, and is still in office at eighty years of age! George Hampton, foreman of the walks and plantations, has forty-seven years to his credit. John Chinnell, foreman over the flower-gardens, slopes, and pleasure-grounds, counts forty-two years' service. William Barker, foreman of Frogmore House Garden, entered the garden as a boy thirty-four years ago. Thomas Edwards, plant foreman and book-keeper, entered the service twenty-five years since. John Dunn, foreman of the fruit department under glass, counts sixteen years' service; and so does J. Jack, foreman in charge of the old Vine and private garden at Hampton Court. James Brown, foreman of the hardy fruit department, fifteen years; James Green, foreman of the Royal Lodge Garden, Windsor Great Park, seven years; J. Allen, having charge of the old Vine at Cumberland Lodge, thirty-three years; and J. Carruthers, having charge of the Royal Pavilion Grounds, Aldershot, seventeen years; the length of service of the eleven men counting 304 years, and an average for each of over twenty seven years. God save the Queen!

The Royal Horticultural Society's next meeting will be held on Tuesday, May 2, in the Drill Hall, Westminster, when a lecture on "The British and Swiss Alpine Floras," will be given by Mr. E. A. N. Arber, B.A., at 3 o'clock.

Linnean Society.—At the meeting to be held on Thursday, May 4, 1899, at 8 p.m., the following papers will be read :—1, "The Position of Anomalurus as indicated by its Myology," by Mr. F. G. PARSONS, F.R.C.S., F.L.S., &c. ; 2, "On Notheia anomala, Harv. et. Bail," by Miss ETHEL S. BARTON ; 3, "On Variation in the Desmidieæ," by G. S. WEST, B.A., A.R.C.S , &c.

ROYAL INSTITUTION OF GREAT BRITAIN.—An interesting course of two lectures on "Water-weeds," by Professor L. C. MIALL, F.R.S., will be delivered on Thursday, May 25, and Thursday, June 1.

SMALL WORMS IN POTS.—The Rev. HILDERIC FRIEND, Ocker Hill, Tipton, writes: "I should be glad if you could inform your readers that I shall be happy to receive and report on small worms found in pots, among flowers, plants, fruits, grass, manure, &c., especially if suspected of being the cause of injury. All helpful information should be sent, and specimens of injured material with living specimens of the worms."

SECRET COMMISSIONS.—The Prevention of Corruption Bill introduced in the House of Lords by the Lord Chief Justice, "may be shortly stated as an effort to check, by making them criminal, a large number of inequitable and illegal secret payments, all of which are dishonest, and tend to shake confidence between man and man, and to discourage honest trade and enterprise." The preamble is, in effect, a copy of the finding on the subject of a special committee appointed by the London Chamber of Commerce, on which twenty of the trade sections of the Chamber were represented. Sections 1 and 2 make the gift, offer, receipt, and solicitation of any corrupt payments offences. Corrupt payments are not defined by the Bill, but certain transactions are declared to be corrupt; and the reason why no attempt is made to define corruption is, "that the thing is so Protean, that to define it is almost impossible." Sections 3 to 8 inclusive contain declarations that certain specific transactions are corrupt unless the contrary be shown ; sections 3 and 4 deal with the common case of gifts to the agent by persons having dealings with his principal; and sections 5 and 6 deal with bribes given, not to the agent, but to his wife or child and others. Sections 7 and 8 deal with a different class of "unconscionable transactions," and seek to put an end to the practice of taking commissions for advice.

DR. A. W. CHAPMAN died at Apalachicola, Florida, on the evening of April 6. He was by far the oldest of the American botanists, having passed or being on the point of passing his ninetieth birthday, and, of course, he was the last survivor of the generation of TORREY, GRAY, ENGELMANN, &c. He is best known for his *Flora of the Southern States*, published originally in 1860, with the cooperation of Prof. EATON as regards the Ferns.

"SOWERBY'S ENGLISH BOTANY."—The proprietors of *Nature* are about to issue a special reprint of that well-known work. The third edition of *Sowerby's English Botany*, to be offered on the instalment system, which has recently become so popular. As in the former editions, all the illustrations will be coloured by hand.

BERLIN HORTICULTURAL EXHIBITION. — The Society for the Encouragement of Horticulture in Germany has arranged that a winter flower-show, inaugurated by them, shall be held during seven days in February, 1900, in the Zoological Gardens, Berlin. The programme, now ready (application to be made to 42, Invalidenstrasse), mentions eighteen sections, in all of which awards are offered for the various exhibits.

DOUBLE ARABIS.—The flowers of the Arabis shown by Messrs. VEITCH & SONS, at the last meeting of the Royal Horticultural Society, prove on examination to be more interesting than was apparent at a glance. The sepals were of the ordinary character, but there were no stamens. In their place were twelve petals, thus making the numerical symmetry complete (S. 4 P 4 An. 4 + An. 4). There was no pistil, but in its place another flower-bud (median prolification).

PRESENTATION. — Mr. H. HUMPHREYS, late head-gardener to A. SPICER, Esq., J.P., The Rookery, St. Mary Cray, was on Thursday, April 6, presented with a very handsome marble clock, towards the cost of which some sixty-three persons subscribed. At the base of the clock was a brass plate bearing the inscription, "Presented to Mr. H. HUMPHREYS by a few friends as a token of esteem, April 6, 1899."

—— Mr. W. WRIGHT, on leaving Ryecroft Nursery, Lewisham, where he had been foreman for eight years, was presented with a handsome marble timepiece by the rest of the employés of the firm, as a token of their esteem.

"THE ROMANCE OF WILD FLOWERS" is, we learn, the title of Mr. EDWARD STEP'S forthcoming work, this being the first volume of a proposed new series to be issued by Messrs. FREDERICK WARNE & Co., under the general title of "The Library of Natural History." The book will be very rich in illustrations reproduced from photographs taken by Mr. STEP and his daughter, as during the past twelve months, whenever anything of interest to illustrate the text was obtainable, the author (who had the opportunity of writing his book amid the surroundings of a Cornish seaside village) availed himself of it. In addition to these illustrations, there are to be upwards of a hundred of a minor character dispersed throughout the volume. Lovers of his two little books, *Wayside and Woodland Blossoms*, and they are numerous, will have a treat to look forward to.

ANNE PRATT'S "FLOWERING PLANTS OF GREAT BRITAIN," will be shortly re-issued in 1*s.* weekly parts. This new edition has been most carefully and sympathetically revised by Mr. EDWARD STEP, F.L.S., and will contain two more plates than the former issues, 315 in all. Practically, for lovers of wild flowers, PRATT'S book has been the authority among illustrated works, over 1,500 species being figured in the coloured plates. The text has been re-set in a larger type than the recent edition. The publishers, Messrs. FREDERICK WARNE & Co., inform us that there are to be thirty-six parts. As the book has now been out of print for some years, and was only obtainable in four volumes at a comparatively high price, this will be good news to lovers of botany, among whom this work requires no recommendation.

TEA ROSE LIBERTY.—According to *American Gardening*, never has Nature yielded to the painstaking hybridist and plant-raiser a more beautiful or more satisfying colour than that seen in the new hybrid Tea Rose Liberty. When we have got to the end of the heroics, we learn that the colour is rich liquid ruby. It was raised at Belfast in the nurseries of Messrs. DICKSON, from a grandchild of Mrs. W. J. Grant by Victor Hugo.

CUBA.—The Americans are turning their new possession to account. According to an advertisement in *American Gardening* we see that "absolutely free warranty deeds" are offered to Americans "in one of the choicest, most beautiful, and fertile spots on the most fertile island in the world." It appears that no English need apply; but the Grapes are not ripe enough for English taste.

FRUIT FROM THE CAPE.—The Union Royal Mail Steamship Company's vessel *Scot*, brought on her last trip 720 boxes of Grapes, 179 boxes of Pears: total, 899 boxes. Some of the Grapes arrived in good condition, although packed in cork and peat-dust, and realised good prices. A large number of boxes arrived in exceedingly bad condition, owing, it is stated, to being badly and insufficiently packed in peat-dust. The shippers in the Colony ran short of the usual wood-wool packing, and had to resort to cork and peat-dust. Forty boxes of Pears contained a hard culinary variety, and were carried in the ship's hold as ordinary cargo, and they arrived in very good condition; the other Pears consisted of dessert varieties which also arrived in good condition.

BOTANIC GARDEN ON THE MALOJA PASS.—Dr. HANS SCHINZ hopes to be able to publish the first account of the results obtained by forming an alpine garden on the Maloja Pass in the annual report for next year of the Zurich Botanic Garden. During the current year several hundreds of specimens from the Engadine have been planted and duly labelled. The Director acknowledges, with many thanks, the assistance rendered to him in this work by Herr G. HEGI, of Zurich.

APPLE ALLEN'S EVERLASTING.—In respect of this Apple, which we figured on p. 222, Mr. GEO. BUNYARD writes: "As a garden tree it forms admirable, rather upright pyramidal examples, which soon attain a fruiting size, and they bear freely and repeatedly. It also succeeds as a cordon or espalier, and will probably make a neat orchard standard. Though this variety has been before the public for nearly 30 years, it is only those who cater for private tables that would notice it, because its appearance is not striking; but as a long keeping fruit of the highest quality and flavour it has few equals. In our fruit-room it retains its flavour and keeps well until April. As the fruits take a long time to mature they should be allowed to hang upon the trees quite into November, and if gathered too soon they will shrivel and become worthless. Keep them in a cool moist position in the fruit-store. The fruits being produced in clusters they should be thinned, or they will not attain perfection.

THE VEGETATION OF THE GLOBE.—Under the title of *Die Vegetation der Erde*, Professors ENGLER and DRUDE are editing a series of monographs on geographical botany. One of the most interesting of these is now before us, in the shape of a monograph on the distribution of plants in the Caucasus, by Dr. GUSTAV RADDE. The work comprises chapters on the Steppes of the Caucasus, the Colchian district, the Caucasian forests, the rock-plants, the Alpine flora of the Caucasus, and other matters. The work is illustrated with numerous photographic illustrations and maps.

A PANSY DISEASE.—Mr. RALPH E. SMITH in the March number of the *Botanical Gazette* (Chicago), describes a "leaf-spot" disease which has been found very destructive in the State of Massachusetts The disease is characterised by the appearance upon affected leaves of circular, dead spots with a distinct black margin. The shape afterwards becomes irregular. The petals also become spotted and often distorted, and no seed is produced. The fungus which causes this disease is called Collectotrichum Violæ-tricoloris. A figure and description are given in the periodical above mentioned.

APPLE-CANKER. — The cause of this malady was for long a subject of discussion, and for some it still is. Those who are of the same opinion as ourselves, that it is caused by fungi, and specially by Nectria ditissima, should show the strength of their convictions by spraying their trees at this season with Bordeaux Mixture as a preventative. Perhaps they will not think it worth while to do so. Meanwhile, the Americans think it worth their while to profit by our negligence by sending us tens of thousands of barrels of Apples. Some of these should be superfluous if our orchardists paid more attention to their business. Mr. W. PADDOCK, in the *Proceedings of the Western New York Horticultural Society*, January 25, 26, has a very suggestive paper on the subject.

FLOWERS AT WEDDINGS, ETC.—There may be noticed an increasing tendency to associate particular flowers with persons and with names. Most people know how lavishly Primroses were used in the decorations in connection with an interesting event that recently occurred in the family of Lord **Rosebery**. The names of the bride suggested the employment of the Primroses, and of Marguerites. The ceremony took place on the day succeeding that commemorative of the death of Lord **Beaconsfield**, or the display of Primroses might have been even greater. During the same week, we read there was a wedding in a pretty little Cotswold village, the bride's name being **Broom**, and that of the bridegroom **Woodroffe**. Therefore the bridesmaids' bouquets were composed of Broom and Woodruff (Asperula). In many cases such a practise may have pleasurable results, but it will be interesting to see when Mr. Leek or Miss Onions takes a similar step, if the blooms of the fragrant Allium will be given distinction in the same way. It would be best after all to avail ourselves of the prettiest and most useful flowers obtainable when decorations are needed, regardless altogether of the imagined significance of their appellations.

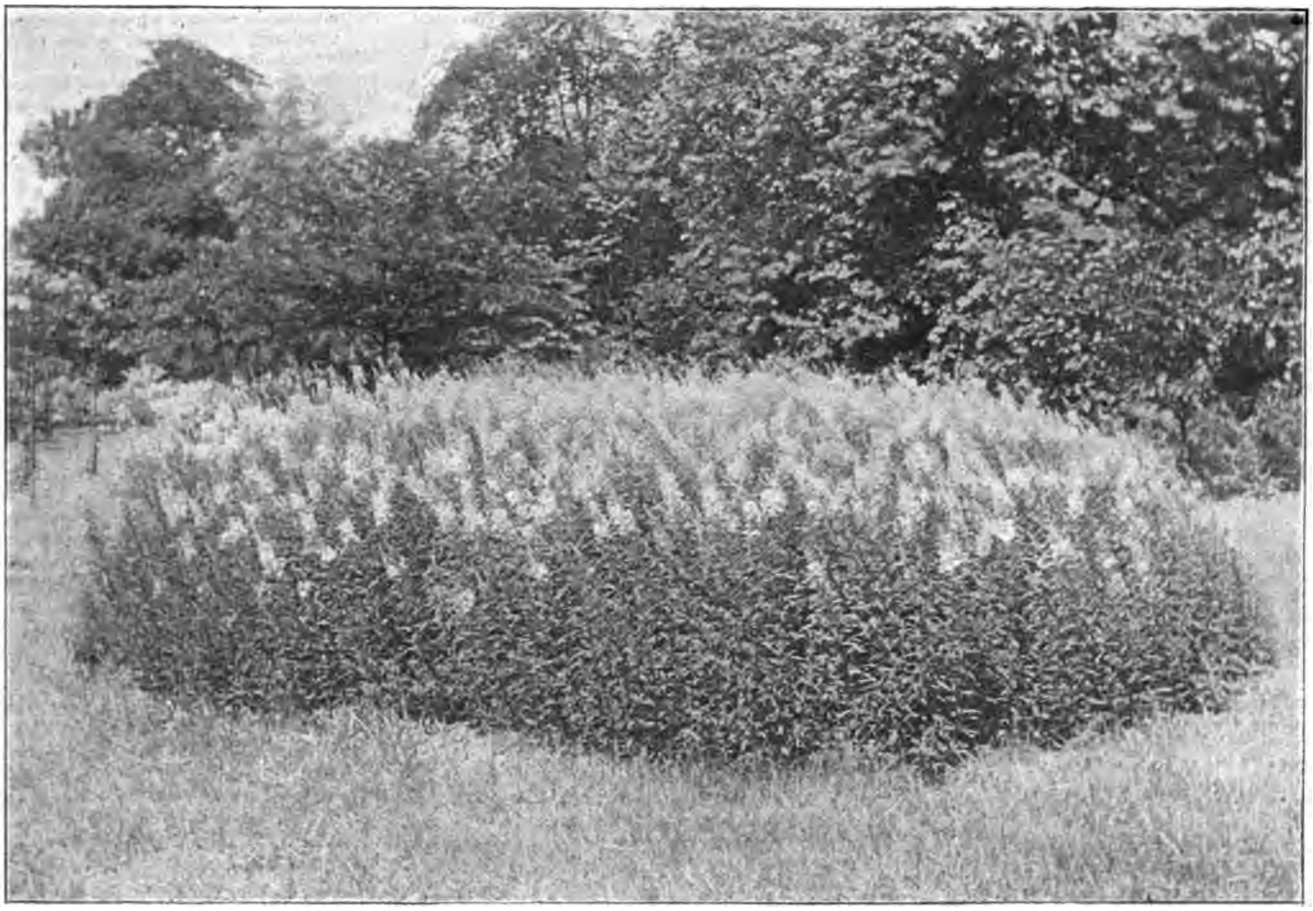

Fig. 99.—A BED OF EPILOBIUM ANGUSTIFOLIUM AT HOLLAND HOUSE. (SEE ANTE, P. 225.)

"**The House-Sparrow.**"—W. B. **Tegetmeier**, F.Z.S. (**Vinton** & Co., 9, New Bridge Street, E.C.).—By everyone save a few sentimentalists, who have nothing to lose by him, the house-sparrow is voted a pest. No careful observer of his habits can spare a good word for him, while traps and snares are devised to defeat even his cunning. The agriculturist bemoans his stolen Wheat, the gardener complains that sparrows pick up numerous seeds, and "devour many seedling plants as fast as they emerge from the ground. In the summer they devour our edible Peas, and where they exist in large numbers they destroy the flower-beds." Mr. **Tegetmeier** treats all said in the defence of these birds with scorn. He thinks little of the theory that the mischievous destruction of hawks, owls, and other carnivorous birds has helped the sparrows to attain their present numbers, and is all in favour of sparrow-clubs and of artful traps, though with some inconsistency he objects to poison as being a "cowardly, painful, and treacherous mode of removing them, which does not commend itself to my consideration, although I confess to drawing a hard and fast line respecting cockroaches and blackbeetles, which can only be exterminated by the continuous use of phosphorus paste." As appendix to the book is included a pamphlet by Miss **Eléanor Ormerod** and W. B. **Tegetmeier**, reprinted from the *Journal of the Royal Horticultural Society*.

Publications Received.—*The Orchid Review*, April, containing notes, papers on "Dendrobium × Ainsworthii as a Wild Plant," Feeding Orchids, Spontaneous hybrids of hardy Orchids, Nomenclature of Hardy Orchids, and similar subjects.—*Bulletin of Miscellaneous Information*, Royal Gardens, Kew, Appendix iii., 1898. List of staffs in botanical departments at home, and in India and the colonies.—*Fruit Growers' Year Book*, 1899 (Hatton House, Great Queen Street, W.C.). This includes an account of Covent Garden, with prices, and description of its management, and fruit notes from various countries. There are also a useful calendar and articles on several fruits.—*Guernsey Growers' Association's Year Book*. Under this somewhat awkward title are included the fourth annual report (satisfactory and progressive, especially as regards exported Narcissus and other flowers); papers on the Arum, Chrysanthemum, and other horticultural topics, and some rules and tables. Bound up in this year-book are the Board of Agriculture's pamphlets on the Barn Owl, Diamond Black Moth, Pear Midge, and Water Wagtail, and also the list of varieties of fruits, issued by the Royal Horticultural Society. These give great value to the publication.—*Guernsey Growers' Gazette*. This is sent every Wednesday to the principal fruit-growers and farmers in the Island, and its contents are appropriate to its destination.—*Queensland Agricultural Journal*, February.—*Agricultural Gazette of New South Wales*, vol. x., part 2, February 1899, with papers on "Native Food Plants and Indigenous Vegetable Drugs," by J. H. Maiden; "The Orange," W. J. Allen; "Hints on Budding," F. J. Ellis; and "Preventatives for Smut," Geo. Valder.—*Agricultural Journal, Cape of Good Hope*, March 16.—*Report of the Natal Botanic Gardens*, for 1898. The Curator, Mr. J. Medley Wood, reports "in all respects a most successful season."—New York Agricultural Experiment Station, Geneva.—*Bulletin* No. 150, 1, Raspberry Saw-fly; 2, Preliminary notes on the Grape-vine flea-beetle; No. 151, Experiments in ringing Grape-vines; No. 152, Two Destructive Orchard Insects; No. 153, Director's Report for 1898; No. 154, Commercial Fertilisers for Potatos.—*Proceedings of the Academy of Natural Science of Philadelphia*, 1898, Part III., September to December.—*Meehans' Monthly*, April, with article and coloured plate of Solidago nemoralis, "Grove Golden-rod."—*Botanical Magazine*, Tokyo, February 20.—*Botanisches Centralblatt*, No. 16.—*Botanische Zeitung*, April 14.—*Handbuch der Botanik* (Breslau).—*Dictionnaire Pratique d'Horticulture*, Livraisons 79, 80, and 81.—*Liste Générale des Membres de la Société Nationale d'Horticulture de France* (Paris), April 1.—*L'Italia Agricola Giornale di Agricoltura*, April 15.—*Westnik* (St. Petersburg).—*The British Moss Flora*, Part XIX., of this periodical bears date February, 1899. We have before remarked upon the excellence of both letterpress and plates prepared by Dr. Braithwaite, which render the volumes of standard interest and value to bryologists.

THE GARDEN AT HOLLAND HOUSE.

(Continued from p. 225.)

The Water Garden. — This high-lying estate is fortunate in having a spring of water at its highest point, the flow from which is allowed to collect in a pool, dug out and hidden in a thicket. The water thus collected is by certain ingenious contrivances led from one part to another on the western side of the north lawn, and supplies, in its course, several square tanks raised above the ground-level, and trickles in narrow channels lined with pebbles from tank to tank, and the overflow from each runs to one at a lower level, and finally reaches a rockery at the boundary of the garden proper.

These overflow runnels afford sites at the sides for numerous dwarf plants, such as Sedges, exotic and native Iris, Cyperus, Thymes, Bamboos, &c., which add greatly to the interest of the garden. The moisture percolates to the right and left of these runnels, and serves to maintain the turf and neighbouring plants in fine condition in the driest years, besides imparting humidity to the air.

The main features of the wild garden, apart from the planting and arrangements found alongside the water-channels, and around the tanks, partake of the formal character of the place, and are therefore quite in harmony with the surroudings; but inside these lines the treatment exhibits considerable freedom. One of the water-tanks previously mentioned is planted with Zizania Indian Rice, and the walls with species of Dianthus. The next tank is planted similarly, but the walls are clothed with dwarf species of Campanula, and Dianthus Napoleon III., a variety raised by Mr. Forbes, of Hawick, N.B., which grows and flowers freely.

The third basin is filled with Marliac's Water Lilies carnea, and others, which flower beautifully; and the wall is planted with Saxifragas. Another tank is filled with Aponogeton distachyon, and the last piece of water that forms a good sized pool is filled with Marliac's Nymphæas, viz., purpurea, rosea, and carnea, and N. odorata, and tuberosa; and around the edge are bunches of Cyperus longus, and various Bamboos, B. Simoni having developed into a mass ten feet through and as much in height. Besides the Bamboos at this part of the grounds a good collection of fine large plants is grown.

On a part of the rockery a trial is being made of species of Opuntia that are likely to prove hardy in this country, but this is only in the experimental stage. Alpine and rock-plants are largely employed along the water courses, and on an extensive rockery, and a considerable degree of success has attended Mr. Dixon's efforts (fig. 100). The remains of an ancient orchard forms a feature in the grounds near the house, the gnarled trunks and limbs and quaint contours of the Apples affording capital contrasts to the stately old Cedars of Lebanon now getting rather bare, the Cupressus, Thuyas, and Planes.

The gardens are full of surprises, and we meet them at every turn. Some portions have not been altered or disturbed for a century or more, and when at distant intervals some alterations and additions have been made, they have followed the formal lines of the old style.

A covered way, built with the southern side open, and furnished with arches resting on square pillars, runs part of the distance from the mansion to the conservatory; Ivy clothes the pillars and hides, or was intended to hide, the rather plain-looking brickwork. This arcade forms a welcome retreat from a sudden storm, and a cool resort on a hot day. The conservatory, originally a coach-house, was many years ago fitted with a glass roof in places, and glazed doors and big windows. It contains a number of aged Camellias, Oranges, Indian Azaleas, Acacias, Oleanders, and others, but it is ill-adapted for the cultivation or preservation of the flowering subjects. The other glass structures are of old date, and not very commodious or useful, according to modern notions.

The oft-repeated statement that plants of other climes, and especially those which come from the pure air of the Alps of Switzerland and other mountanous regions, will not succeed in London, will be taken with a certain amount of incredulity by those who have scanned this article and noted the great variety of tree and shrub, herbaceous, perennial and alpine, which not merely exist but grow with freedom in this garden. *Apropos* of alpines, mention should be made of Campanula Fosteri, which, when sent over to Mr. Dixon by M. H. Correvon, of the Jardin d'Acclimatation, Geneva, was stated by the latter to be very unlikely to succeed at Kensington, as it needed mountain air, together with certain conditions not to be obtained there; yet this purely alpine plant is at this date perfectly healthy, and it is making fair growth.

The kitchen-garden, an apparently productive piece of land, is situated on the western side of the estate. Its vegetable quarters are bounded by healthy espalier Pear and Apple-trees, of remarkable height and breadth.

We may say, then, that the garden pleases by what is reminiscent of other days, as well as by what is of recent creation. And both the old and the new are very different to the ordinary run of private gardens, and on that account delightful to the non-gardening visitor and gardener alike. For ourselves, we look on much of the gardening there as experimental, and shall watch with interest the behaviour of many of the plants growing in the open air. That which will succeed at Kensington ought to do so in most if not all of our parks and public gardens.

HOME CORRESPONDENCE.

DOES PRIMULA SINENSIS CAUSE SKIN IRRITATION?—I have a staff of workmen who are continually engaged in handling this plant during its season of growth; and the foreman tells me that though he has known no case of eczema being caused thereby, yet a painful irritation is felt when, for instance, a workman rubs his eyes with his hands, and the smart will continue for some quarter of an hour. This is especially the case during hot weather, when the face is moist through perspiration. *Ernst Benary, Erfurt, Germany.*

PRIMULA OBCONICA CAUSING IRRITATION.—I am sorry to see so many complaints in the *Gardeners' Chronicle* against what I consider the most useful of all Primulas, whether for the provision of flowers for cutting, or as pot plants. I hear of gardens from which it has been banished, not because it has affected any one, but because the plant has now obtained a bad name. On the contrary, I have discarded all other Primulas in its favour, and intend to grow it in increased quantity. I have 200 plants this year, which are perfect masses of flower and foliage. By selecting and crossing the best colours for some years, I have now many beautiful shades of colour, and the plants are of a dwarf habit. *W. W., N.B.* [A number of blooms and foliage of P. obconica that accompanied the above note were wonderfully fine, the size of blooms and of foliage being uncommonly large. In colour, the flowers vary from what is almost white to very deep rose—deeper than we have previously seen these flowers. Nevertheless, "W. W.," we shall be inclined to exercise care in handling these glorious specimens. Ed.]

CHRYSANTHEMUM L. CANNING.—We are sending a few blooms of this white Chrysanthemum. We commenced to cut blooms (for sale) of this excellent late variety last December, and have had a constant supply from that date until April 15. From 400 plants, in 6-inch pots, we have cut 2200 fine blooms. We take our cuttings of this variety in May, for if late blooms are required the cuttings should not be struck early. *W. & J. Brown, Nurserymen, Stamford and Peterboro.* [The blooms sent with the above note are fresh, and but partially expanded. Ed.].

VIOLET LADY HUME CAMPBELL.—In answer to the enquiry in last week's issue, the above Violet was brought by Lady Hume Campbell from Milan, about 1878, and was exhibited by Mr. Brush at the Royal Horticultural Society, in 1881, and sent out by Mr. Charles Turner the same year. *T.*

—— I remember that this variety originated with, or was first grown by Mr. Brush, who was gardener to Lady Hume Campbell, Eastcote, near Pinner. I think the stock of it passed into the hands of Mr. C. Turner, who distributed it. There is little if any difference between this and the variety De Parme. *C. H.*

—— I cannot give the parentage of this splendid Violet, because, since I took charge of these gardens, I have not met Mr. Brush the gardener, who, it is alleged, was the raiser of the variety. I have no reason to doubt that it originated at this place [?], and was named in honour of his employer, Lady Hume Campbell. *F. Strong, gr., Highgrove, Middlesex.*

PROPAGATING VIOLETS.—I notice in the "Week's Work," on p. 246, that Mr. Fielder recommends a method which I disagree with. It is, I submit, better just before lifting for the winter to take as many cuttings as one requires for another season, and insert them in cold frames or boxes in a compost of light sandy and leafy soil. These cuttings will, if well looked after, make excellent plants for the following spring without disturbing the old clumps in the frames, which must be more or less exhausted with flowering, and cannot compare with the plants raised from cuttings by my method. No one need fear that they will not grow large enough, for they both make larger clumps and produce better blooms, and are not so liable to attacks of red-spider, or to die off, as the others. I have, now, two three-light frames of Lady Hume Campbell, which are a mass of blossoms which it would be a great pity to disturb when one can get such good results in the manner named. *F. Strong, gr., Highgrove, Middlesex.*

BIRDS AND FRUIT TREES.—I agree with most of that which Mr. C. Herrin wrote on p. 246, but from personal observation I do not think tom-tits destroy fruit-buds, as on more than one occasion, when waiting under Apple trees with a gun for bullfinches, I have noticed tom-tits settle over my head, open the buds and examine them for insects, and also in Pear trees, but in no case could I discover that the tom-tits had destroyed the bloom-buds. I know to my cost in some seasons that they are partial to late Peas, and have the mischievous habit of pecking the stalk-ends of Pears, but in the matter of fruit-buds I think they are often blamed for the damage done by the fruit-grower's worst enemy, the bullfinch. We know that insects are the natural food of the tits, and in times of insect scarcity a few pounds of suet suspended in various parts of a garden will keep tom-tits from doing harm to the fruit-blossoms. *R. M., Newbury.*

FERN STEALING.—I enclose you a full report of an important case tried at our County Court, Friday, 21st inst., in which London Fern-collectors were convicted (see p. 271 in present issue). By one report, Love is shown to have been fined £5 and costs; and by another, mulcted in that sum or the alternative of two months imprisonment with hard labour. There has been much grumbling in this county lately at the depredations of these Fern-collectors, and any further cases will, I hear, be dealt with pretty severely. These vagrant collectors know the popular sorts of Ferns, and, passing over the common kinds, take the more marketable and rarer sorts found in our lanes and on our hills. The slopes of the Haldon range were and are still fairly rich in Ferns, and so are some of our woody glens and commons near the valley of the Otter and near Exeter, but this wholesale plundering is much impoverishing them. *Andrew Hope, Exeter.*

MARÉCHAL NIEL ROSE.—While carefully reading the thoughtful and interesting notes of Mr. William Earley and "A. D." (p. 220, *Gardeners' Chronicle*), yesterday I received the following note from Mr. Todd, the art florist of Maitland Street, Edinburgh, who has probably handled as many Maréchal Niels and other Roses as any other living man:—"It occurs to me," writes Mr. Todd, "that you would be interested to know that the finest Niels ever offered for sale in Edinburgh

Market have been there for the past two Saturdays. They are grown by Mr. Turner, who holds the gardens of Dalhousie Gardens as a market-garden. The Niels are on their own roots; and for foliage, substance of bloom, richness of colouring, and strength of stem, would not be easily beaten." This is not merely a plant with an odd bloom or two, but from one large plant and two smaller ones. Mr. Turner has cut during the last ten days some 700, and there are plenty more to come. Mr. Todd also mentions that many years ago, his father grew a large plant of Maréchal Niel that got latterly on its own roots when the stock failed, and produced fine crops year after year. I have also handled good Maréchals on their own roots, and have seen magnificent examples in Herts, Cambridge, Middlesex, and other counties. I have been to see some of the Dalhousie Roses to-day and find them all that Mr. Todd describes in his note before me. Growing the Maréchal Niel Rose on its own roots, does not, however, wholly avert the unwholesome swelling, though it goes a long way towards curing their next most persistent fault, the drooping of the blooms. I can hardly recall a case in which own-rooted Niels did not stand up more strongly in consequence, for the flower-shoots on own-rooted Niels are longer as well as stronger than those of worked plants. Possibly a liberal thinning of the flower-buds might strengthen as well as lengthen the flower-stems, as well as help to cure the swelling. Doubtless very many market-growers of M. Neil, will ask with Mr. Todd, why all this difficulty as to the most suitable stock if this success can be obtained without a stock at all. *D. T. Fish.*

THE TAXATION OF GARDENERS.—Mr. Treeby's case, referred to so fully in the *Gardeners' Chronicle* recently, has, because of the wide publicity given to it, helped to draw attention to the harm done to the gardener's vocation by the excise laws, which regard the gardener as a mere luxury for the wealthy, and not as an ordinary worker seeking a livelihood. Of course, it is answered, that if gardeners can only be kept when a license-duty is paid for them, it cannot affect the worker, because the employer has to pay the tax; but the gardener may well ask why out of the myriads of vocations of an essentially industrious and productive nature, he should be singled out for taxation? Engineers, clerks, foremen, carpenters, bricklayers, and millions of other workers whose wages exceed those of the gardener three, four, or five times in amount, are non-licensed. Is not the gardener as much a producer and a necessity in our midst as is any one otherwise occupied? Is not this license-duty a tax on labour, and if paid by the employer, does it not serve to check employment, because the employer finds or regards licences of this nature as specially onerous and deterring? We are so apt to accept what is, and to lightly regard the evil that it may be doing. Surely we have in the kingdom no occupation that is more useful, more worthy of all encouragement, than is that of the gardener. Yet we have for years submitted to the imposition on the gardener and his labour of a tax that is a direct impost on labour. Ought not gardening to be relieved from this burthen and stigma? It is most oppressive on the best trained element in horticulture, whilst the mere labourer escapes. In reference to Mr. Treeby's case, I could but think what would happen if he tried to get over the Inland Revenue Department by sending one man half a week to Mr. Estcourt's garden, and a second man the other half. [Or he might send a man for five and a half days only.] How would the case stand then? *A. D.*

A NARCISSUS SOCIETY.—It is now the custom to establish a society to promote the culture and exhibition of a particular flower, and so it need cause no surprise that one outcome of the recent Narcissus show at Birmingham may be the establishment of a Daffodil society, with Birmingham for its centre. At that exhibition Narcissus cultivators were present from diverse parts of the country, and at a dinner held at the Midland Hotel on the evening of the first day, an opinion was generally expressed not only that it would be a proper step to form such a society, but also to have in connection with it a journal, monthly or otherwise, in the interest of the Narcissus. Instances were given of the misconceptions regarding the treatment of the Daffodil by persons who make an attempt to grow it, and it was thought that a journal conducted by some competent authority would be of great service. Whether both or either of these propositions are likely to become actualities, remains to be seen. *D.*

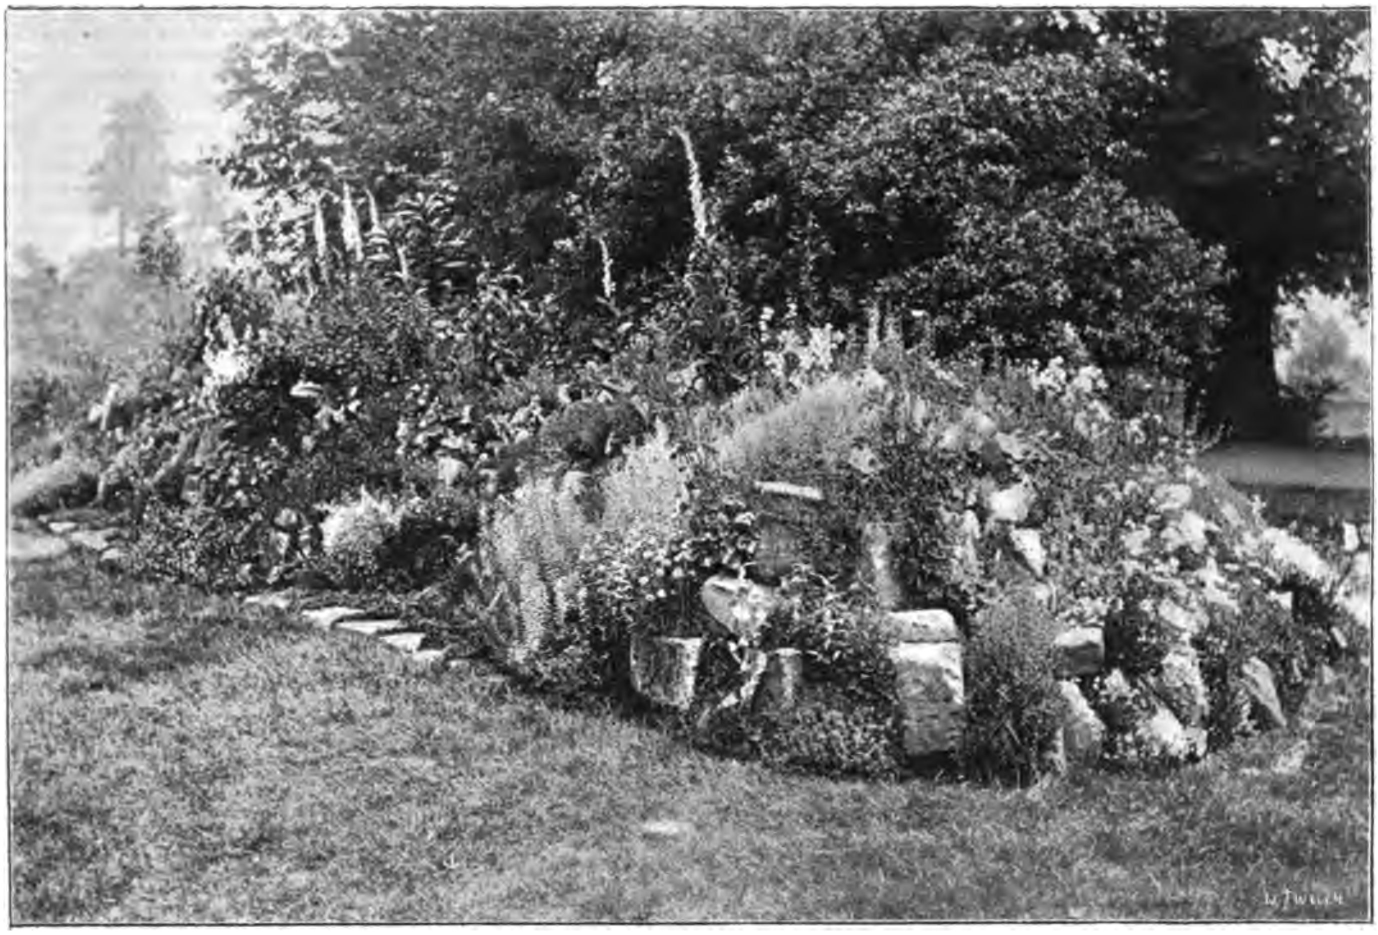

Fig. 100.—The Rock-garden, Holland House. (See p. 268.)

CAMELLIAS (See also p. 262).—In reply to your correspondent, "R. C.," in last week's issue of the *Gardeners' Chronicle*, I may say that it is generally recommended to repot Camellias in the autumn, after the flower-buds have set, affording a small shift, and a soil consisting of fibrous loam, with the addition of a small quantity of peat and sand, and pruning to take place in the spring, cutting away any weak and sappy growth, and stopping any shoots not required for extension, according to the shape of plant it is desired to grow. I believe most varieties succeed equally well, either in pots or on a border. There are gardeners whose methods differ from mine. *E. H. S.*

ROYAL GARDENERS' ORPHAN FUND.—When all is said and done, I imagine no practical amendment of any faults there may be in connection with voting for candidates is likely to be made as long as human nature is what it is. Little or no fault can be found with the rules or the management. What is faulty, is that subscribers, when they vote, forget the benevolent intentions of the fund, and allow interests and influence to hold sway. And has it not always been the same in connection with the Gardeners' Royal Benevolent Society? As I take it, filling up these voting-papers is a most responsible undertaking, and we are in duty bound to weigh well the many calls for help, and to vote on the merits of the candidates only. Is this always done? Do not trade influences, personal friendships, and the like, too frequently influence votes, and the election of candidates? What may be termed the minority clause, or cumulative annual votes, registered in favour of candidates who are not successful, seem to be the only hope of those candidates who have only the merits of their cases to depend upon. My only doubt when I moved and carried on the G. R. B. I. committee the clause that gardeners in receipt of £30 per annum should be eligible was, whether it were not better to maintain the original limit of £20, so that the poorer they were, the more the benefit was needed, and would be appreciated. *William Earley.* [If the committee made the selection of the candidates, and left the members to ratify the selection, or to propose other candidates, much trouble, expense, and needless anxiety would be spared. Ed.]

SPARROWS, SHREW-MICE, AND CARNATIONS.—I can quite confirm that the sparrows are the miscreants that injure the Carnations. I have seen them doing it. A few years ago the leaves were eaten off in a much neater fashion by a shrew-mouse. In that case the leaves were cut off short by the sharp teeth of the animal, but the ends of the leaves injured by sparrows are smashed by their beaks like the end of a cooked Asparagus that has been sucked. I find they do it whenever the temperature is colder. It almost certainly indicates a frost or a cold spell; I presume under these conditions the foliage becomes sweet. Polyanthuses and Primroses, I notice, are chiefly bitten off on the shady side of the garden, or from weak plants. Those in full sun and flourishing are rarely touched. Black thread over the plants is the only protection I find of any use; the birds catch their wings in it, and are apparently afraid of not getting away in time. For the Carnation, soot is certainly useful till washed off, and is good for the health of the plants when that happens. *E. M. H.* [Campanula muralis and Agrostemma Flors Jovis have been terribly mauled by the sparrows this year; perhaps pigeons aided in the destruction. Ed.].

WINTER SALADS.—I am situate only about 5 miles from Sidmouth, where your correspondent, Mr. Milne-Redhead, obtained such poor salads towards the end of February. With a good supply of Hick's Hardy White Cos, and All-the-year-round Cabbage Lettuce, from seeds sown in the third week in July, and again a month later, and which we plant out in an open spot, I can obtain in four seasons out of five good heads of Lettuce well into December. I have raised a good number of the Cabbage variety that had well-formed heads at the end of October, when they were planted in cold, freely-ventilated pits, and placed as near the glass as possible, but the results have not been satisfactory. Such plants soon decay, or, failing this, make elongated stalks, which render them unfit for the salad-bowl. Time back I have made a hot-bed of leaves and stable-dung early in January, and placed 1 foot of soil thereon, and when I found the heat declining have planted a good batch of Cabbage Lettuces, that had been standing at the foot of a south or west wall. They were planted thickly, and were only covered at night or during rain. From such plants I have cut fairly good heads early in March, but this method necessitates much labour, and is seldom adopted. We are never able to cut a moderately good Lettuce from the open until the first week in April, when Lee's Hardy Green or Hammersmith may possibly be had, followed by Hick's Hardy White Cos, a capital Lettuce for use early in May, and for standing through the winter in Devon. *J. Mayne, Bicton.*

—— All of the correspondents who have written of winter salads omit one useful addition to the salad-bowl, viz., Corn Salad, or Lamb's Lettuce. This plant is much appreciated by those who like salads as they are served on the Continent. Seeds should be sown in mid-autumn, and when the ground is not too dry; and two or three s made at intervals will afford a sufficient supply till Lettuces are ready for consumption in the spring. The Cos Lettuces are all of them very unsatisfactory when forced in frames, and in the open I find it is useless to attempt to grow them even in South Devon, some 12 miles distant from Sidmouth, unless planted in a single row, close to the walls of forcing-pits, or any warm-house. Lettuces for winter should be grown in frames, placed on a mild hot-bed of leaves and stable-litter, and from the time of planting until the Lettuces are ready to cut a very small amount of air should be admitted to them. The best variety for this season, and the quickest to turn in, is Veitch's Golden Queen, which is a compact head, of a pale yellow colour. *T. H. Slade, Poltimore Gardens.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

Present: Dr. M. T. Masters (in the Chair); Mr. H. Selfe Leonard, Rev. W. Wilks, Mr. Elwes, and Rev. G. Henslow, Hon. Secretary.

Alpine Auriculas, Mildewed.—A plant was received from Rev. C. Wolley-Dod infected by a fungus. It was forwarded to Dr. W. G. Smith for examination.

Apple-wood, Diseased.—Some specimens received from Mr. Basham were also sent to Dr. Smith.

Germination of Daphne Mezereum.—Mr. Elwes described some curious differences between the germination of some seeds of this shrub, in which the plumule grew up normally above-ground; while in others, from some unaccountable cause, it appeared to be arrested for a long period before appearing, although they sent down roots underground in the usual way.

Hyacinth Stem and Leaves Growing Downwards.—Mr. Henslow showed a plant, the bulb of which had been accidentally inserted upside down. The roots had grown normally downwards; but the shoot, instead of turning upward towards the light, had also grown vertically downwards, the greatest energy of growth being at the base of the leaves. It subsequently elevated the bulb into the air, removing all the roots from the soil, and continued to grow solely at the expense of the nourishment contained in the bulb. The flower-stalk, closely invested by the leaves, was 7 inches in length.

Carnations attacked by Acarus.—Mr. Michael reported upon the specimens sent to the last meeting as follows:—"The Carnation pest is a Tarsonymus. All this genus are destructive and difficult to eradicate, in consequence of their leaf and stalk-mining habits."

Diseased Carnations.—Dr. W. G. Smith, Leeds, reports as follows:—" On the Carnations sent none of the fungi usually present was found, e.g., rust, leaf-spot, fairy ring-spot. The symptoms presented are those of the disease known as 'bacteriosis.' This is the name given by Arthur and Bolley (Purdue Univ. Agric. Exp. Station, *Bulletin* 59, 1896), because they ascribed the disease to the action of a Bacterium (B. dianthi). They were able to infect healthy plants with cultures from diseased specimens. A Belgian investigator, Paul Nypels, published in 1898 (*Notes Pathologiques*), some observations on the disease, which point to some other agent than bacteria as the primary cause. Other workers also hold this view. The disease is well known, and very destructive in the indoor cultivation of Carnations in the United States and in Belgium. The conditions favourable to it are overcrowding, defective ventilation, and the effect of moisture on the foliage, due to overhead watering. Prevention is evident, except for the last item mentioned; but overhead watering must be reduced as much as possible. The structure of the Carnation-leaf indicates a plant suited to a dry open situation, like our native Dianthus, on rocks, old walls, and open pastures. In indoor cultivation means must be adopted to prevent too frequent wetting of the foliage. This has been done by some growers in America, as described by Arthur and Bolley. Pieces of wire-netting bent into a Λ shape are placed between the rows of plants, so as to keep the lower leaves clear of the stages. The water is then applied by means of a hose directed into the Λ, and the water is distributed to the roots by a nozzle, delivering on both sides. Arthur and Bolley give illustrations in paper sent herewith. The method has been successful against this and other diseases of indoor Carnations. Where this disease has already shown itself, it may be checked by spraying the foliage with Bordeaux Mixture."

Vines Malformed.—Mr. G. Wythes, of Syon House, sent branches of Vines with malformed flowering bunches, supposed to be due to fog, but they presented a not uncommon condition of being tendrils bearing abortive buds. As Darwin, and many others before him, point out, Vine tendrils are homologous with flowering shoots, and such transitional states between simple tendrils and bud-bearing ones occur on all Vines, and have nothing to do with external climatic conditions.

Effect of Lightning on an Oak.—A specimen received from Dr. Plowright, of Lynn, showed how Oak-wood is sometimes torn into longitudinal fibres by electricity. "The trunk from which this specimen was taken was that of a tree grown in East Anglia, and purchased for timber by a timber-merchant in King's Lynn, from whose wood-yard it was obtained. The amount of injury was comparatively slight, consisting only of a groove cut from top to bottom of the trunk, about 2 inches wide, and extending only a very short distance into the woody tissues, but tearing them up longitudinally into strips several feet in length."

Witches' Broom on a Scotch Fir.—This was received from Dr. Plowright, who writes:—"The specimen is sent by Hamon L'Estrange, Esq., and was found growing upon one of the Fir-trees in his park at Hunstanton Hall, Norfolk. It consists of a mass of hypertrophied 'dormant buds,' measuring a metre in circumference round its widest part, and weighs 2¼ kilogrammes. It is borne upon a branch which shows eight angular rings, and springs from a lateral shoot. It is interesting to observe that this shoot is itself hypertrophied, as compared with the corresponding one on the opposite side of the branch, but that this hypertrophy only extends as far as the growth, beyond which it is atrophied and dead. The growth itself consists of seven or eight rounded masses, composed of aborted shoots—partially developed buds closely aggregated. The masses are of varying ages, some bearing green leaves, while others are quite dry and dead." The origin is supposed, in some cases, to be due to the attack of a Phytoptus, in others to a fungus, Æcidium.

Malformed Bulbous Plants.—A quantity of decayed and arrested bulbous plants were received, both from St. John's Wood Cemetery, Marylebone, and from Lincoln's Inn Fields. Both cases illustrated the effect of premature growth from the very mild winter, followed by severe check during the week of frost, and subsequently by excessive wet. Mr. Henslow observed that on the high ground and clay soil of Holland Park, bulbs have come up exceedingly well, having been planted in September.

Apple Trees affected by Grubs.—Specimens received from the Chiswick Gardens were referred to Mr. McLachlan, who has reported as follows:—"The larvæ in the Apple-twigs are no doubt those of Laverna vinolentella, which was formerly considered a variety of L. atra (the larva of which feeds on the fruit of Hawthorn), but is now regarded as distinct. I am not aware that it has ever been found sufficiently common to occasion serious damage; but as the egg is, no doubt, laid in or on a bud, and the depredation primarily confined to the bud, it is evident that the question of serious damage is only one of degree.

Odontoglossum crispum.—Dr. Masters exhibited a spray on which every flower had three, and sometimes four, stamens instead of one only. It was received from Mr. Young.

Jatropha podagrica. — This scarlet-flowered species was awarded a Botanical Certificate. It is a well-known plant in botanical gardens.

MIDLAND DAFFODIL.

April 13, 14.—There were exhibitors from all parts of the country; Ireland sent fine contributions. The show-house of the Botanical Gardens, Edgbaston, was taxed to the utmost to provide the necessary space.

But one collection of not fewer than fifty varieties competed for the Silver Daffodil Cup, given by Messrs. Barr & Son, it came from the Rev. J. Jacobs, Whitewell Rectory, Whitchurch, Salop.

There were three competitors in the class for twelve varieties of true Trumpet Daffodils, Mr. W. J. Grant, Bassaleg, Newport, Mon., taking the 1st prize with very good blooms.

There were thirteen stands of six distinct varieties. Mr. J. C. Williams, Caerhays, Stansted, was 1st, having very fine examples of Victoria, Glory of Leyden, Emperor, Weardale Perfection, Horsefieldi, and Madame de Graaff.

With twelve distinct varieties of Medio coronate Daffodils, Miss Currey was placed 1st with finely-developed blooms of Barri conspicuus, Lulworth, pure white perianth, with a bright orange cup; Queen Sophia, Duchess of Westminster, Madame M. de Graaff, and Commander. There were nine competitors, with six varieties, Mr. J. C. Williams taking the 1st prize with Sea Gull, White Lady, Albatross, Dorothy York, and seedlings, all very good.

The Parvi coronate Daffodils were also very good, and comprised varieties from two sections, viz., Burbidgei and Poeticus. Mr. W. J. Grant was 1st with twelve, having excellent examples of Falstaff, Constance, Præcox grandiflorus, Baroness Heath, angustifolius, Princess Louise, &c.

Mr. P. D. Williams was 1st out of nine competitors, with six varieties, having in fine form John Bain, Ornatus Beatrice Hesseltine, and seedlings.

DAFFODILS IN POTS.

By way of giving additional interest to the show, there were classes for Daffodils grown in pots. In that for twelve varieties, Mr. R. Sydenham took the 1st prize for finely-grown and flowered plants of leading varieties; and Mr. R. C. Cartwright for six pots. There were classes also for Polyanthus Narcissi in pots, finely-grown and flowered specimens being staged.

There were two classes for Daffodils as well as Polyanthus Narcissi grown in bowls with cocoa-fibre, all well done, and proving what fine blooms can be obtained in this way.

TULIPS.

A class for six pots of early single Tulips was a very attractive feature. Mr. R. Sydenham was 1st, staging finely-grown and flowered varieties, such as Van Spaendock, Unique, Prince of Austria, Proserpine broken, &c. Tulips were also shown in bunches.

There were classes for Cinerarias, herbaceous Calceolarias, Lily of the Valley, Lilium Harrisii, and Cyclamen.

Of seedling Narcissus, Certificates of Merit were awarded to Parvi coronate, Incognita, white perianth, with large, deep golden cup, edged with red; Edmond's white Medio-coronate, white, with sulphur cup; Firebrand Parvi-coronate, white, with orange-scarlet cup of a brilliant colour, from the Rev. G. H. Engleheart. To Trumpet variety Duchess of Bedford, from Messrs. Barr & Sons, King Street, Covent Garden; and to Messrs. Pope & Son, nurserymen, Birmingham, for Pope's King, a fine deep golden variety, regarded as a distinct improvement upon Golden Spur.

Collections of Daffodils in great variety were staged by R. H. Bath, Ltd., Wisbech; Messrs. Barr & Sons; Messrs. Hogg & Robertson, Dublin, who had in addition a large and interesting collection of Tulips; T. S. Ware, Ltd., Tottenham; and R. Sydenham. Messrs. Hewitt & Co., Solihull, had charming decorations in Daffodils; and Messrs. Sampson & Co., Florists, Birmingham, a collection of cut Daffodils.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

April 18.—At a meeting held on the above date, there were present G. Shorland Ball, Esq. (in the chair), and Messrs. W. Thompson, G. W. Law-Schofield, H. Greenwood, P. Weathers, J. Cypher, W. Holmes, W. Stevens, R. Johnson, and T. Mills (Hon. Sec.).

Thomas Statter, Esq., Whitefield (gr., Mr. Johnson), showed among other plants Cattleya intermedia alba (First-class Certificate), and Cypripedium Godefroyæ Veitchi (Award of Merit).

Saml. Gratrix, Esq., Whalley Range (gr., Mr. McLeod), showed Dendrobium Wardianum Gratrixi (First-class Certificate), Dendrobium Falconeri giganteum (Award of Merit), Lælio-Cattleya Hon. Mrs. Astor (Award of Merit), Cypripedium insigne, Harefield Hall variety (First-class Certificate), and Odontoglossum triumphans (Award of Merit).

John Leemann, Esq., Heaton Mersey (gr., Mr. Edge), showed Cattleya Lawrenceana (Award of Merit), Odontoglossum crispum (Award of Merit), a Cypripedium hybrid from bellatulum, and some other species (First-class Certificate).

Dr. E. J. Sidebotham, Bowdon (gr., Mr. Shiner), was awarded a First-class Certificate for Cypripedium caudatum Wallisii.

Hy. Greenwood, Esq., Haslingden (gr., Mr. Gill), showed Odontoglossum Humeanum, H. Greenwood's variety (Award of Merit), O. nebulosum (Award of Merit), Dendrobium Clytie (Findlayanum × Leechianum) (Award of Merit), D. nobile nivalis; D. n. Highfield variety (Award of Merit).

O. O. Wrigley, Esq., Bury (gr., Mr. Rogers), showed Cypripedium Argus Moensæ (Award of Merit), C. villosum aureum magnificum (Award of Merit), Dendrobium nobile symmetry (Award of Merit), Cypripedium Mastersianum superbum (Award of Merit), and other plants.

Mrs. Briggs, Bury, Accrington (gr., Mr. Wilkinson), obtained an Award of Merit for an Odontoglossum hybrid.

J. Charlton Parr, Esq., Warrington (gr., Mr. Masterton), showed a collection of cut blooms, for which he was awarded a Cultural Certificate.

Edward Holt, Esq., Prestwich (gr., Mr. Murphy), received a Vote of Thanks also for cut blooms.

Captain J. Barlow showed Chysis bractescens (First-class Certificate and Cultural certificate).

Mr. James Cypher, Cheltenham, showed Cypripedium Winifred Hollington (Award of Merit); C. niveum grandiflorum (Award of Merit); Odontoglossum Rossii Amesianum (Award of Merit); Lælio-Cattleya Highburyensis (Award of Merit); and Epidendendrum bicornutum (First-class Certificate).

Messrs. F. Sander & Co., St. Albans, showed Cypripedium × cilholare × niveum (Award of Merit).

DUMFRIES AND GALLOWAY HORTICULTURAL.

April 18.—On the above date a lecture on "Daffodils" was delivered by Mr. S. Arnott, Carsethorn, who briefly sketched the history of the Daffodil, discussed its cultivation, and also gave detailed descriptions of the principal representatives of the different groups.

There was a large collection of Daffodils and other spring flowers, including Orchids, from various growers. Owing to the unfavourable weather, the local growers were not so well represented as they otherwise would have been. Those showing flowers were as follows: — Messrs. Barr & Sons, London; Messrs. Hogg & Robertson, Dublin; Messrs. Smith & Co., Worcester; Messrs. Kerr Bros., Dumfries; Mr. James Service, Maxwelltown; Mr. James Davidson of Summerville, Maxwelltown (gr., Mr. W. Caldow); Mr. John Primrose, Arunel House, Maxwelltown (gr., Mr. Jas. Allan); Mr. Galbraith, Terregles (gr., Mr. J. McKinnon; Mr. W. Boyd, Melrose; and Mr. S. Arnott, Carsethorn. A large consignment from Mr. W. B. Hartland, Cork, arrived too early for use.

NATIONAL AURICULA & PRIMULA.

April 18 (*Continued from p.* 250).

Of Miscellaneous exhibits partaking of the character of the show, Mr. J. H. Arkwright's grand yellow Primrose, Evelyn Arkwright, appeared to be finer than ever. It is evidently cultivated in a manner that brings out in the highest degree the possibilities of this fine variety. Mr. J. C. Arkwright, also hailing from Hampton Court, Leominster, had a collection of Primulas of various types. Species of Auriculas, Polyanthus, Primroses, &c.

The Guildford Hardy Plant Nursery Co., had a basket of pretty, small-growing species of Primulas, bedded in Sempervivum and rockwork. It was a meritorious object-lesson in arrangement.

Messrs. Geo. Jackman & Son, Woking, had in a large collection of plants, a panel of various double Primroses, and also collections of single Primroses and Polyanthus, with varieties of P. Sieboldi.

Messrs. Collins Bros. & Gabriel, florists, Hampton, staged a large and varied collection of Polyanthus in pots, which formed an attractive feature.

If a supplemental Auricula show could be held on May 2, a very fine display would be forthcoming, as the main of the Auriculas will then be at their best. The date was too early this year, the spring being so retarding, but the wisest among us cannot possibly foretell the character of the weather in the changeful month of April.

CHESTERFIELD AND DISTRICT CHRYSANTHEMUM.

April 19.—The fifth annual show of spring flowers in connection with the above Society was held in the grounds of Whittington Hall.

Four tastefully-arranged groups, each about 100 square feet, occupied the centre of the tent, the exhibitors being Mr. Nelson, gr. to A. Barnes, Esq., Ashgate Lodge; Mr. Horsnall, gr. to J. E. Clayton, Esq., Thornfield; Mr. Bloxham, gr. to R. F. Mills, Esq., Tapton Grove; and Mr. Jenkinson, gr. to Mrs. Burkitt, Stubbing Court.

Mr. Nelson had excellent Daffodils in pots, also Staphylea colchica, Cannas, Azaleas, &c.

Owing to the extreme lateness of the season, the display of hardy flowers was disappointing.

Mr. Nelson was successful with Hyacinths, Azaleas, Palms, greenhouse and stove flowers, and exhibited a well-grown and finely-flowered plant of Dendrobium thyrsiflorum, which was greatly admired.

Messrs. Proctor & Sons, Chesterfield, made an attractive display of Boronias Ericas, Cytisus, pot-Roses, and Hydrangea Hortensia. Mrs. Shentall showed a fine collection of Narcissus

LAW NOTES.

PROSECUTION OF FERN COLLECTORS.

Proceedings at Exeter.

At the Castle of Exeter, April 21, before Mr. E. F. Studd (in the chair) and Sir Robert Newman, Jack Sanders, *alias* Smith, of no fixed abode, was charged with having, on March 29, done wilful damage to certain real property at Kenn, to the extent of 1*s.* 6*d.*, the property of Mr. J. H. Ley. George Adams and Jack Sanders were jointly charged with wilfully damaging certain property at Haldon on the 30th of last month, the property of Mr. Short. Thomas Love, general dealer, of Covent Garden, was summoned for aiding and abetting the two former defendants to commit the said damage within the last six months. Adams and Sanders appeared in the custody of two warders, they being undergoing a term of imprisonment for a like offence in Dorset. Mr. Baker (Messrs. Dunn & Baker) appeared for Love, who pleaded not guilty.

Henry Palmer, bailiff, said that on the day in question he was in a wood at Kenn, near Round Hole. He there saw the two men digging Ferns. They had a mattock and trowel with them. There was a horse and cart there which bore the name of T. Love, but he could not say what the address was.

P.-C. Ridler said on Thursday, March 30, he was on duty at Haldon, where he saw Adams and Smith, who gave the names of T. Love and Jack Sanders. The men were then on Mr. Ley's estate. Witness saw Adams pulling up the Ferns, and Smith was putting them in a bag. Witness followed them up the road, and saw they had a pony and cart there, which bore the name of T. Love. There were about seventy or eighty roots in the bag.

Thomas Love, general dealer was then put in the witness-box, and stated that he lived at Battersea, and carried on business in Covent Garden. He bought Ferns when they were brought to him. He had Ferns from a lot of people, but never gave instructions with reference to them, nor did he know how the men obtained them. He had not received a communication from Adams to say the Ferns were coming.

The Bench, after a short deliberation, addressing George Adams, stated that he had been to prison several times and fined for similar offences, and he was now undergoing a term of imprisonment for a like offence. He would be sentenced to one month's imprisonment for each offence, the sentence to run concurrently. With regard to Jack Sanders, they thought he was not so much to blame as Adams. They thought he had been led away by him, and as he was undergoing a term of one month's imprisonment, he was sentenced to one week for each offence. As to the case against Thomas Love, they had not the slightest doubt from the evidence that he was guilty. A fine of £5 and costs (£11 18*s.*) was imposed upon him.

Obituary.

Mr. J. W. Chard.—The death of Mr. J. W. Chard, at Clapham Common, on the 23rd ult., at the age of seventy-five years, recalls to memory one who was a central figure at horticultural exhibitions a generation ago, and who was a worthy member of the craft, able, manly, upright, and courteous. Born in London in 1824, he began his gardening career by being apprenticed to Mr. Woodin, gardener to Sir George Robinson, Bart., Cranford Hall, Kettering, and after his term of service there he went to the Pine-apple Place Nursery of Messrs. Arthur Henderson & Co., St. John's Wood, who sent him as foreman to Mr. Dedman, gardener to Sir Samuel Scott, Bart., Sundridge Park, Kent, and from there he went at twenty-one years of age as gardener to Sir Frederick Bathurst, Bart., Clarendon Park, Salisbury, where he greatly distinguished himself as a cultivator and exhibitor of specimen plants, Roses, and table decorations. In regard to the latter he displayed a considerable amount of originality of design and good taste, making his mark at the exhibitions of the Royal Horticultural and the Royal Botanic Societies, also at the Crystal Palace, the Agricultural Hall, and the Alexandra Palace. He also went further afield with his exhibits, and scored successes at Birmingham, Brighton, Bath, Exeter, Weston-super-Mare, Taunton, Trowbridge, Liverpool, &c. Of silver cups, gold and silver medals, he won many, generally choosing plate in preference to medals. His powers of endurance must have been great, for there was scarcely a horticultural exhibition of note but he was there competing. For the space of twenty-six years he was at Clarendon Park, leaving there for the suburbs of London, where he commenced the profession of a landscape gardener, and was most successful in his undertakings. Energetic to the last, he may be said to have died at his post, for he was out among his men the day before his death.

Always regarded as an honourable and painstaking judge, his services were in considerable request in that capacity. He leaves a widow; and his son, Mr. J. R. Chard, is widely known as a floral decorator at Stoke Newington. This worthy gardener was laid to rest on the 27th ult.

ENQUIRIES.

Mr. Henry Reid enquires, "What would be the result, if any, to stove and greenhouse plants, Vines, &c., growing in a structure lighted by electricity, supposing all the iron rods for opening ventilators, &c., connected with the said structure, were carrying the current." Will some correspondent kindly afford an answer to his enquiry.

Odd volumes or separate plates of the *Botanical Magazine* or *Botanical Register* are required. Will any reader who has such plates kindly communicate with "Librarian," care of the editor of the *Gardeners' Chronicle.*

ANSWERS TO CORRESPONDENTS

Basic-slag and Kainit as Manures for Tomatos: *E. F. C.* Such a slowly decaying phosphatic manure as basic-slag is scarcely to be recommended for a plant so short-lived as the Tomato, and as the manure is insoluble in water before it decays, it is a wasteful practice to use it. Bone-meal or bone-black are better fertilisers, and good Peruvian guano best of all. Kainit contains potash in the form of sulphate, the average being 12·5 per cent. of actual potash, 23 per cent. of the sulphate, and 33 per cent. of ordinary salt. If its use is intended to benefit the immediate crop, it should be applied several weeks before the crop is planted. Potash is a very suitable manure for the Tomato-plant, especially the late fruiters, which grow to a large size. One application, together with farmyard dung, may reach 2 oz. per square yard.

Books: *E. J.* Manuals on Tomato and Cucumber culture are to be purchased of Mr. Upcott Gill, 170, Strand, W.C. *Select Ferns and Lycopods*, by B. S. Williams, to be had at the Victoria Nurseries, Upper Holloway. *Mushrooms for the Million*, by J. Wright, published at the office of the *Journal of Horticulture*, 12, Mitre Court Chambers, Fleet Street, E.C.

Broad Beans: *H. W.* The seeds had been inhabited by the grubs of the Bean-weevil (Bruchus granarius), which feeding on the substance of the seeds had caused the malformation of the cotyledons. The browning or rust noted, is, we think, due to frost, and it affects only one side of a plant, that was doubtless more fully exposed to the air-currents during the continuance of the frost. You should examine your seed-Beans, picking out all weevil-infested seeds, and burning them forthwith. You will know them by a small round hole observable in every Bean containing a weevil-grub. The perfect beetle is not found inside of the bean. The plants, or the majority of them, will recover, and afford a crop of pods. Let the rows be moulded up, and, as the garden is a very draughty one, put up some wind-breaks here and there between the rows of Beans, &c, such as sheep-hurdles, evergreen-branches, rows of closely set pea-sticks, &c.

Buyers of Lily of the Valley and Roses: *W. G. B.* We are unable to name any. You might enquire of the chief florists in Covent Garden; or, what is better, advertise them to be sent for cash to private customers, making use of the parcel-post and railway facilities.

Heating Houses: *Economist.* A horticultural builder or the boiler-maker might be able to inform you of the probable quantity of coke required for a year; but we are unable to do so, knowing nothing of the consumption of a Boulton & Paul boiler; moreover, the quantity of fuel burned would in a great measure depend on the character of the winter and spring weather, much less being necessary in mild ones than in severe, and on the stoking.

Horticultural Press: *Alpha.* Appointments of this kind are not numerous, and vacancies do not often occur. You could qualify yourself by writing on matters you personally know something about, or by describing honestly and faithfully what you see, and narrating truthfully what you hear, that is of horticultural interest. If you send matter of this kind to an editor, it is pretty sure to be accepted. Editors are deluged with "copy," but much of it is, from one cause or another, declined. Your letter shows that you write a good handwriting, that you spell well, and express yourself clearly—all points of great importance; but you introduce irrelevant matter, which, supposing it were intended for publication, would be deleted by the editor. We congratulate you on the results of your examination, but no one would suppose, as you seem to imply they would do, that, by reason of your success in the examination-room, you were competent to incur the responsibility of undertaking the cultivation of the plants you wrote about. For that, experience is needed, and you cannot get that by passing an examination. You ought, nevertheless, to gain your experience more thoroughly, speedily, and easily, by having previously been trained and taught what to see, and to what subjects your attention should be directed. We cannot answer your question as to your chances in America, but we believe you might, as you say, enter some of the classes at Cornell or other Universities. Write and ask at headquarters. We cannot answer your question about county councils, but again advise you to apply at headquarters. In the meantime, secure a reputation for diligence and character, and make yourself as useful as you can to your superiors. You will then benefit by the "influence" they very properly exert. Scan the advertising columns, and generally keep a good watch for what may turn up. We have answered you at some length, because the information you seek is often wanted by others, to whom we cannot reply individually.

Lilac: *J. P.* The variety brought from Paris is Syringa japonica, a comparatively recent introduction. Its flowers are white, and need not therefore be forced in darkness to blanch them. The other Lilacs enquired about are Charles X. and the Marly varieties. Last year was unfavourable to Lilacs on the continent, the excessive drought rendering the growth very slow and short, and many cultivators, noting this, afforded the plants water too late, and for too long a time, in late summer and autumn, with the result that a second growth was made, which in many instances failed to ripen, hence the fewness and small size of the blooms this year. Lilacs can be grown in this country to flower as well as those grown abroad if the right kind of attention be afforded. Supposing the plants bought in have been purposely grown for flowering in pots, either forced or otherwise, they should be planted out in May in a very warm spot—a south border in the kitchen-garden is the best in this country, the distance from plant to plant being from 2 to 3 feet, according to size, no manure being employed if the land is in good heart. The balls should be somewhat reduced in size, and some small amount of root-pruning performed, and the remaining roots outside the ball laid in the soil carefully, the latter being firmly packed round about the sides of the ball. The top of the ball need not be put deeper than 1 inch below the surface, and if a slight basin be formed round each it will be all the better in case water has to be applied. All weak wood must be pruned off, and only strong wood allowed to remain then, and during the summer, the object being the production of six to eight good strong flowering shoots of medium length. There must be no stopping of the shoots intended to carry bloom, and all stem-shoots and those coming from the root must be suppressed. No inter-cropping ought to be allowed, and also no mulching, but the surface must be often hoed, so as to permit sun-heat to enter the soil. Ordinarily, water is not wanted after the first month, nor later than the second week in August, but no rule can be laid down in this matter, soils and seasons differing so much. The ordinary Lilac-bush, as grown in nurseries for out-of-door planting, will not do as a pot-plant, as it has, as a rule, received no special treatment, and usually consists of a number of shoots springing from the root, whereas a prepared Lilac-plant has a short clean stem, surmounted by a crown of shoots. For early flowering, the plants should be taken up with root-mass intact as soon as the foliage is ripe, and there is still enough warmth in the air to induce the formation of roots. The pots should be just large enough to take the mass, together with a little fresh soil, the potting being carefully and firmly done, but not so firmly as to injure the roots. Afford water immediately, and stand the potted plants in a half-shaded place. The best kind of soil is heavy loam, rendered porous by the addition of leaf-soil (quarter) and half a peck of sand to a wheel-barrow full of soil. The potted plants may be kept packed in a leaf-bed out-doors, or in a turf-pit.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*W. C.* Garden-raised Caladiums and Crotons vary so much, that it is impossible for any but a grower to name them.—*Seeds.* The flowers sent are those of seminal varieties of Rhododendron Edgeworthi, R. fragrantissimum, and perhaps, some Himalayan species. Send them to some nurseryman who grows these plants extensively.—*C. W. D.* A species of Viola, probably a white variety of V. odorata, that has been dyed scarlet.—*J. H. B.* We cannot undertake to name varieties of Daffodils. Send them to one of the large trade growers.—*J. H.* 1, Pulmonaria officinalis; 2, Not recognisable; 3, Phlox subulata; 4, Alchemilla arvensis; 5, Lysimachia Nummularia; 6, A species of Helianthemum, Rock Rose.—*S. N.* Hibiscus sp., perhaps H. Abelmoschus. If you will kindly send a better specimen later on, we may be able to speak more definitely.—*C. A. B.* 1, Kerria japonica; 2, Berberis (Mahonia) Aquifolium; 3, Orobus vernus; 4, Ornithogalum nutans; 5, Tulipa sylvestris; 6, Primula cortusoides.—*F. F.* Epimedium pinnatum.—*P. B.* 1, Potamogeton; perhaps P. obtusifolius; 2, Saxifraga cordifolia; 3, Bridgesia spicata; 4, Berberis Darwini; 5, Stachys germanica; 6, Phalaris arundinacea, with variegated leaves.—*D. D.* Pieris floribunda.—*Tester.* 1, Acer platanoides; 2, Forsythia suspensa; 3, Buddleia globosa; 4, Habrothamnus fasciculatus; 5, Populus balsamifera, probably—what a scrap!; 6, Pulmonaria officinalis; 7, Pyrus Malus floribunda.—*Novice.* 1, N. bicolor; 2, Narcissus major; 3, N. telamonius plenus; 4, N. odorus double; 5, N. minor; 6, Lælia superbiens.—*J. D. A.* 1, Dendrobium Devonianum; 2, Dendrobium pulchellum of gardens; 3, Pentas carnea: 4, Selaginella cæsia arborea.—*Mac.* 1, Cyrtomium Fortunei; 2, Pteris argyræa; 3, Pteris tremula; 4, Adiantum formosum; 5, Pteris longifolia; 6, Cyrtomium falcatum.—*J. K.* 1, Oncidium luridum; 2, Cymbidium aloefolium; 3, Oncidium Cavendishianum; 4, Dendrobium Pierardi; 5, Dendrobium thyrsiflorum.—*K. P.* 1, Miltonia flavescens; 2, Oncidium sphacelatum.—*W. A.* 1, Phyllocactus crenatus; 2, Phyllocactus Ackermanni.

Peach-leaves: *W. B.* The silver-leaf disease, the exact cause of which is not known; cut away the diseased portions, grow the plants well, feed well, and try a solution of sulphate of iron (green vitriol), half-an-ounce to two gallons of water.

Pelargonium Constance: *H. & B., Twickenham.* We can find no evidence of disease upon your plant. It is much more likely that the leaves have been withered by some liquid that has been poured over them. The roots and stem are perfectly healthy.

Spotted Leaves: *Thirty-five Years' Subscriber.* The spots on the foliage of Dendrobium sent may have arisen from something unusual or accidental during the past season, the summer of which was unusually trying. If the damage does not arise from disease, the plants may be grown out of it. We do not think it contagious. In Dendrobiums, spot of this kind often appears where the growths have not been properly ripened; and if your remark, "the plants have for many years been grown in the same house," may be taken literally, it would seem to indicate that the cooler resting season had not been observed.

Tomatos in Unheated House: *W. W.* Plant out early in May, and if cold weather at night occurs afterwards you must afford protection, either by covering the roof or the plants.

Vine and Peach Leaves: *G. W.* The leaves sent show scalding, the result of lack of ventilation during a burst of bright sunshine, or from the house remaining closed to a late hour in the morning.

Vines: *J. E. Wing.* The warty under surface shows a want of balance between the air admitted and the aërial moisture in the house. You can remedy this by affording more air, if necessary using fire-heat by day in greater amount. There is no disease.—*W. P.* The leaves are affected with mildew, and you had better make use forthwith of sulphide of potassium, ½ ounce in a gallon of rain-water. The mildew has doubtless killed the tissues of the leaves and berries wherever it has attached itself, and the latter will have to be cut out of the bunches, for the affected parts of the skin ceasing to grow, the berries will split. Maintain a warmer and rather drier air, and paint the heating apparatus with sublimed sulphur, besides keeping this substance mixed with water in saucers placed about the vinery.

THE
Gardeners' Chronicle
No. 645.—SATURDAY, MAY 6, 1899.

BURFORD.

IN speaking or writing of the famous gardens of Sir Trevor Lawrence, Bart., the President of the Royal Horticultural Society, his personal and inherited hobby, the Orchids always present themselves first, and invariably the Burford collection is adjudged the most varied and thoroughly representative collection which has ever been got together, and in which the handsome and rare species both new and old, the curious and botanical, and the garden hybrids, in the production of which Burford has taken such an important part, all take prominent places, and one section is not allowed to encroach detrimentally on the other.

But those who are conversant with the gardens, also know that what is true of the Orchids, is true also of the whole of the gardens, both outdoors and in, for no more truly representative garden probably has ever existed, the skill and care which Mr. W. H. White, the Orchid-grower, bestows on the Orchids being equalled by the diligent attention given by Mr. W. Bain, the gardener to the rest of the garden, in which at all seasons the best plants of the period are to be found grown up to their very best condition.

We call to mind the many different garden scenes, varying with the season, which we have seen at Burford, each differing widely from the other, but all having the constant feature of the pleasant homestead nestling in the nook formed by Boxhill, whose rugged and chalky face, studded with the Gueldres Rose, Box-bushes, and other low shrubs, imparts a stately natural beauty, which Art could imitate, but not rival.

At the entrance-lodge the tall, straight-stemmed trees, the lower part of whose trunks are clad with Ivy, a carpeting of which, studded with low Yew-bushes and Butcher's Broom, form another pretty feature; and the carriage-drive, with its rows of pyramidal Cupressus Lawsoniana, serve to give an admirable contrast to the larger trees in the pleasure-ground beyond.

In the gardens around the house in the summer-time the central basin has a fine show of the new coloured Water-Lilies, and Tuberous Begonias, Cannas and other bright flowers, make an effective display. The gardens outside the plant-houses are trial-grounds, into which all well-accredited novelties, both of shrubby plants and bulbs or annuals, are admitted, and if they are not up to the standard, they are soon destroyed; but if of merit superior to any of their class, a stock is quickly worked up sufficient to show the subject at its best during the next year, and with the skilful culture given it here, many a novelty springs into notoriety. Recently the Narcissus, Scillas, Chionodoxa, Snowdrop, and other spring bulbs supplied the chief of the outdoor flowers.

Nearer the plant-houses is a pretty rugged dell, the sides clad with Ivy, Ferns, and dwarf Box bushes, and from the bottom of which spread lofty trees, which give a grateful shade in summer.

THE ORCHID-HOUSES

have their best show now made by the Dendrobiums, many of the hybrids being raised at Burford. In the large warm-house, one side had a very fine show, in which the Burford type of Dendrobium × Wiganiæ gave an admirable illustration of the beauty and variety to be obtained by the hybridist using exceptionally fine varieties to seed from. The many plants of it in bloom showed it to be of very free habit, the stems of some being over 3 feet long, and furnished with bloom the greater part of their length. One handsome form, D. × W. xanthochilum, had bright dark yellow flowers with purple eye, and was even richer in colour than D. signatum, one of the parents; while other forms closely approached D. nobile, the other agent used, and might be mistaken for a yellow-tinted D. nobile.

Other instances of exceptional beauty in hybrids were evidenced in the Burford-raised D. × Juno, D. × Euterpe, D. × melanodiscum, D. × Aurora, and D. × Clio. Other hybrids finely in bloom were Dendrobium × Cordelia, with ten growths; D. × Rolfeæ, D. × Aspasia, many varieties of D. × Burfordiense, D. × splendidissimum grandiflorum, D. × Euryclea, and many others; and among the species, D. nobile nobilius, D. n. Sanderianum, D. n. Murrhiniacum, and other varieties of D. nobile; D. lasioglossum, D. Falconeri giganteum, D. aggregatum, D. subclausum, D. Capillipes, D. albo-sanguineum, D. cucullatum giganteum, D. Johannis, D. superbum giganteum, D. Dalhousieanum, D. tortile, D. crepidatum, D. secundum, and D. s. album; and among the species not yet flowered, plants of the Mysore D. Jerdonianum, a singular red-flowered species, and others of great interest.

On the other side of the house is a bank of large specimens of the warm-house Cypripediums, many of which are in bloom, and on those of marbled foliage like C. Lawrenceanum, their beautiful foliage is enough to warrant the care bestowed on them. The centre of interest, perhaps, is the fine plant of Cypripedium Stonei platytænium (fig. 104, p. 281), which has attracted so many admirers whenever it has flowered, and whose history since its first appearance in Mr. Day's collection as a chance imported plant in 1867, demonstrated how a beautiful and well defined variation may increase in favour and proportionately in value in spite of the many other novelties annually distributed. Nothing yet has appeared like C. Stonei platytænium and probably were the plants in Sir Trevor Lawrence's and Baron Schroder's collection put on the market, it would be found that nothing had attained their value. The plant from which the illustration was taken has five growths. In the case of the plant in question there is reason for coveting it for its stately cream-white rose-crimson marked flowers, are striking and beautiful, even to those who know not its value. In the fine bank of plants in bloom are large specimens of the typical C. Stonei, C. Rothschildianum, with two strong spikes of five flowers; C. Chamberlainianum, C. × Winnianum, C. Mastersianum (fig. 101, p. 274), &c. At one end is a healthy collection of Phalænopsis, some of them in bloom; and overhead a splendid collection of Bulbophyllums, Cirrhopetalums, Megacliniums, and allied species, which are also giving their share of interesting subjects in flower, one of the most remarkable being the sensitive feathery-lipped B. barbigerum.

The Odontoglossums are in splendid condition, and in their culture at Burford the large new Odontoglossum-house has been a great acquisition. When necessity involved the keeping of the plants in other houses not specially constructed for them, the most constant vigilance was required to keep them up to the mark, but since the fresh arrangements have been made the Odontoglossums grow in the most satisfactory manner, their stout, sleek pseudo-bulbs and fleshy green leaves being pleasant to behold, even when not in flower. Here, as in a few other places of late, it has been the practice to abandon the crocking the pots for Odontoglossums as far as possible, the drainage being supplied by the Bracken-rhizomes in the peat, which in many places has been previously wasted. The best results have arisen, for the plants take to the material, which is a natural vehicle for moisture. In flower are some fine forms of O. crispum, both white and spotted; some grand O. Halli, one fine form having a spike of sixteen flowers, while another has an inflorescence over 6 feet, and bearing eight branches. Also in bloom are some fine violet-coloured O. Edwardi, O. mulus, O. prionopetalon, O. Wilckeanum, O. luteo-purpureum, and some magnificent dark forms of O. luteo-purpureum. In these cool-houses, too, the many plants of O. varicosum, O. concolor, and other highland species thrive well, the O. concolor sending out spikes freely.

The Masdevallias have never given any trouble at Burford, their compact cool house having always suited them well, and the outcome of clean unspotted foliage and a profusion of flowers resulted. Of those in flower in more or less quantity were remarked varieties of M. ignea, and M. coccinea, M. Veitchiana, M. × falcata, M. triangularis, M. polysticta, M. caloptera, M. × Parlatoreana, M. × Hincksiana, M. × Shuttryana and variety Chamberlainiana, M. Armini, M. Shuttleworthi and variety xanthocorys, M. × Gelengiana, M. × Courtauldiana, M. × Asmodia, M. Sororia, M. maculata, &c.; and among the singular small-growing species, M. Simula, and the rare M. O'Brieniana. Here, too, the singular Pleurothallis, Octomerias, and Stelis are accommodated, some of them nearly always in flower.

Of the other great sections cultivated at Burford, the Cattleyas and Lælias have the least in flower at the present time, contributing only some of the smaller species, although among the Cattleyas a few bright specimens of C. Lawrenceana, one of them bearing sixteen fine flowers, tell what a fine species it is when properly grown. A plant also of C. × Lawre-Mossiæ show that its good properties may be communicated. Among those to flower later are the fine white Cattleya Mossiæ Wagneri, with five flower-sheaths; C. intermedia alba, &c.; and among the hybrids in bloom are Lælio-Cattleya × The Hon. Mrs. Astor, with charming yellowish, rose-tinted flowers, and one or two others.

In the large house, the centre table of which is occupied by the showy Sobralias, the remarkable collection of Epidendrums which always give interesting things in bloom, have now open the pretty and rare E. Endresii with several heads of white and violet flowers. Dipping in rain-water overhead several times a week and lightly sponging the leaves, is here said to ensure success with this beautiful little plant. With it are its hybrids, E. × Endresio-Wallisii, E. × elegantulum and its variety leucochilum, and also their parent E. Wallisii. With them are E. tridactylum, E. Jurgenseni, E. Schomburgki, E. × xantho-radicans, and some other red-flowered hybrids; E. × O'Brieniana, E. diffusum, E. fuscatum, E. polybulbon, and other singular and pretty species. One side is occupied by a fine bank of Miltonia vexillaria in splendid condition, with M. × Bleuana well in flower. Beside them are a fine batch of M. Roezli in grand order, with a few in flower; and a lot of M. Phalænopsis, which are flourishing unusually well, for it often gives trouble. Then comes the collection of Cœlogynes, with a fine mass of C. conferta and others in bloom. In the warm seedling-house a very interesting lot of hybrids are coming on, and in other parts in bloom are Bifrenaria Harrisoniæ, and its yellow variety; some Lycastes, Zygopetalum Clayii, the fine scarlet Epiphronitis × Veitchi (one of the most satis-

factory of hybrids), Dendrobium Kingianum and D. K. album, Catasetum Warscewiczii, Maxillaria Houtteana, and, as usual at Burford, a great number of things which cannot be recorded.

In the Anthurium-house is a good show of A. Scherzerianum, and the white, scarlet-spotted varieties of it raised at Burford, and in the greenhouse a good show of spring flowers.

WHEAT AND TULIPS.*

(*Continued from p. 257.*)

THE primitive home of the genus Tulipa is without doubt to be sought in the East, and almost every species is there indigenous, and only T. sylvestris and T. Celsiana had spread over the whole of South-western Europe in prehistoric times. Various forms may have wandered in various directions round the Mediterranean basin, and most of them, as so many other Mediterranean plants, may have followed the African coast. Two members of the group, viz., Tulipa fragrans and T. primulina, remained African; and another, viz., T. transtagana crossed to the Iberian peninsula. The isolation of T. sylvestris in Greece and Sicily must be due, the author thinks, to their disappearance in Asia Minor and Northern Africa.

The views expressed in regard to the distribution of the genus are admitted to be hypothetical, and the surest proof would be without doubt an exact and careful investigation of the spread of the yellow Tulip in the Balkan peninsula, in which manner the members of the genus have wandered north and south. We must wait a long time for this being carried out with living plants, and the difficulty of determining species in the dried state.

With regard to the red-coloured and variegated Tulips, these were not found in Europe before 1559, although there are faint traces of an earlier acquaintance with them. In the museum of the Vatican an antique mosaic shows a flower-basket, in which, by the unanimous verdict of various botanists and others, what are nothing less than red Tulips are portrayed among other flowers. Still, as the Tulip does not occur in any other antique wall mosaics that have come down to our day, one must be careful in their use as a proof of the existence of the red Tulip in Europe. The mosaic in question was discovered about the end of the last century in the garden of some villa of the Roma vecchia, at a spot between Porta San Sebastiano and Cecilia Metella. If it is in its original completeness, or has been restored by a modern artist, is not known, though such occurrences are not uncommon. Moreover, mosaics being costly objects, were often carried by their possessors from place to place, and the one in the Vatican may have been made in some Eastern land—in Asia Minor, or Syria, where the red Tulip is a field flower.

In the 17th century, red Tulips were common plants, and they may be divided by historical evidence into the two sections, Palæo and Neo-tulipæ. In the case of the former we note the commencement of acclimatation similarly to T. sylvestris in the 18th century after being brought as a decorative garden plant in the previous century from the East.

The Neo-tulipæ came into Europe suddenly and naturally in the present century, and there are no literary data relating to them.

Among the older forms, Tulipa Clusiana is mentioned as being of very extensive distribution at the present time, reaching from Schiraz and Syria through the Grecian Archipelago, Italy, Southern France, and as far as Spain and Portugal; but within these borders, the places where it is found in any abundance are much scattered and isolated. The species was known by Clusius and his successors as T. persica præcox; also by Parkinson and Ray. It is a species much more liable to be influenced by its surroundings than T. sylvestris; and, on the other hand, owing to the abundance of its progeny, it has overrun as large an area as that species, and even the most northerly parts of its home, as in a vineyard near St. Pierre d'Albegny, in Savoy; and in a plantation near Biviers by Grenoble great quantities of the plant have been found, and the cultivators have been at great pains to destroy it as an injurious weed, and so far with apparent success.

The second place among the old Tulips belongs to the fine Tulipa oculus solis St. Amans, which is confined to-day to Italy and France on one side, and to Syria (Aleppo) on the other side. In the countries lying betwixt these, it is, so far as we know, non-existent. According to Reboul first, and Mattei later, this species was cultivated in Dutch gardens in the time of Clusius. It appears to the author that it was T. oculus solis St. Amans which Parkinson had in mind, and not T. præcox when he described "but the leaves here are alwayes long and somewhat narrow, having a large black bottome, made like unto a cheurne, the point whereof riseth up unto the middle of the leafe, higher than any other Tulipa." Cheurne being a form of the word chevern; and, in fact, the form of the basal spot agrees to a certain extent with that of a little fish, and that, more by T. oculus solis than T. præcox, whilst the pleasant fragrance is absent from both the species in question.

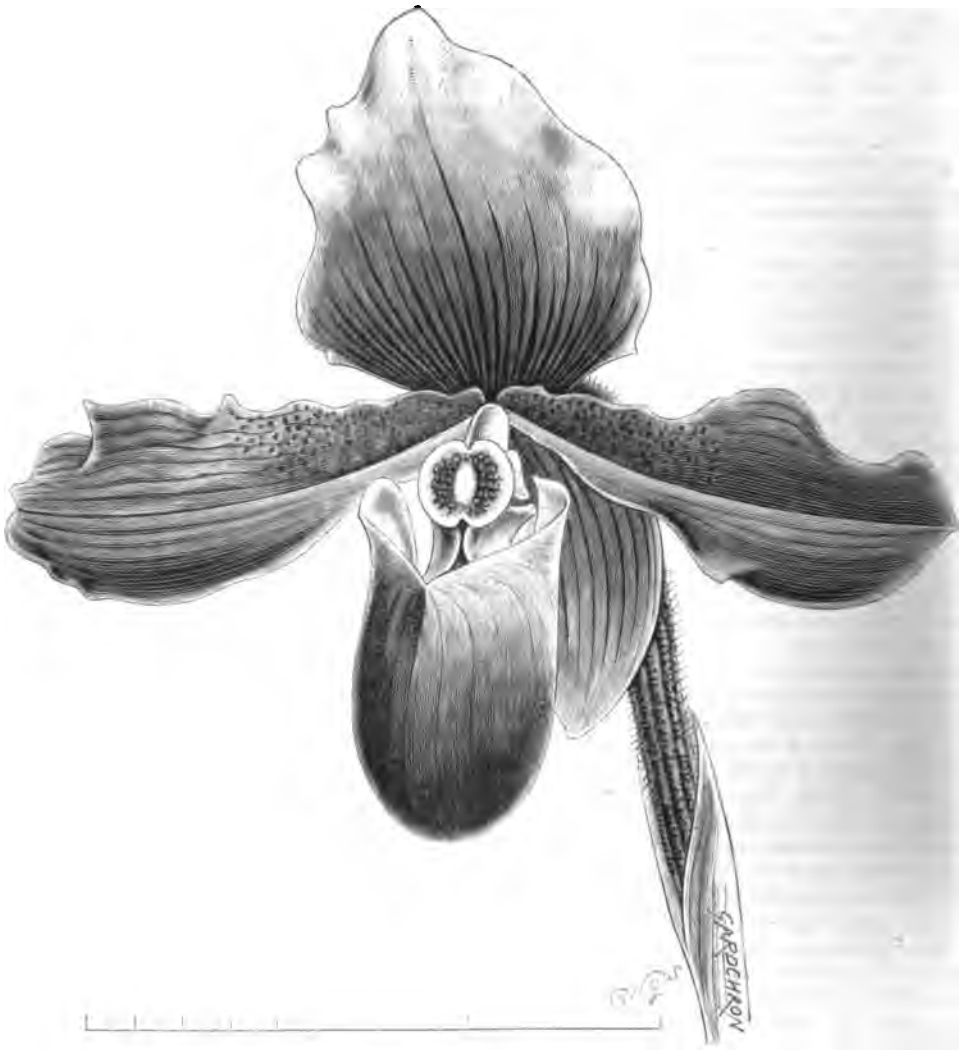

FIG. 101.—CYPRIPEDIUM MASTERSIANUM. (SEE P. 273.)

As early as 1636, a Tulip which was either T. oculus solis or T. præcox, was in cultivation at Paris, as Simon Pauli's catalogue of the gardens there contains a description of a *T. pyrisina sen bombycina medio flore rubro unguibus purpureis sulfureo circulo cinctis*. The plant was found in cultivated fields, by the borders of roads, at St. Amans, near Agen, in southern France, in the early part of the present century, and was described in *Recueil de la Soc. Agricole d'Agen*, and also in the *Flore Agenaise* in 1821. Possibly it existed in Southern France still earlier, at least as early as 1715, in the vicinity of Aix, in Provence. At the present time it is a form met with in many places. There cannot be any doubt as to its eastern origin, but the

---

[*] *Weizen und Tulpe und deren Geschichte*, von H. Grafen zu Solms-Laubach, Professor der Botanik an der Universitat, Strasburg. (Leipzig: Verlag von Arthur Felix, 1899.)

precise locality is uncertain, as it is only found on cultivated land.

Quite recently the firm of Dammann & Co., of San Teduccio, near Naples, have introduced a species found near Arnasia, in Pontus, its natural habitat, under the name of T. Dammanniana, a name that is unfortunate, seeing that Regel discovered a quite different species in Turkestan which he described as T. Dammanni. This T. Dammanniana grown in a garden at Strasburg appears more insignificant than T. oculus solis, although resembling it in all essential particulars; and the author agrees with Mattei that it is the primitive form of our cultivated plant.

The most abundant red-flowered Tulip of Italy is T. præcox, which has been known since 1811. The new Tulips which the author now undertakes to find the origin of, are very remarkable appearances in the European flora. They cannot be identified with Oriental species, and they appeared suddenly in well-known floricultural centres, "like a maiden from abroad," without anyone asking or making a note about their origin. The most remarkable fact is their distribution. The majority are found in groups together in the vicinity of inhabited places, especially near Florence, Bologna, and St. Jean de Maurienne in Savoy.

The first of these forms T. connivens, and T. strangulata var. Bonarotiana, were found by Reboul, in 1822, at Florence. In 1823 came T. maleolens, serotina, strangulata, variopicta, and neglecta, in the same district. There are several others found in the above-named places which cannot be identified with any known wild species, although T. strangulata is regarded as coming near to the Greek species, T. bœotica.

(*To be continued.*)

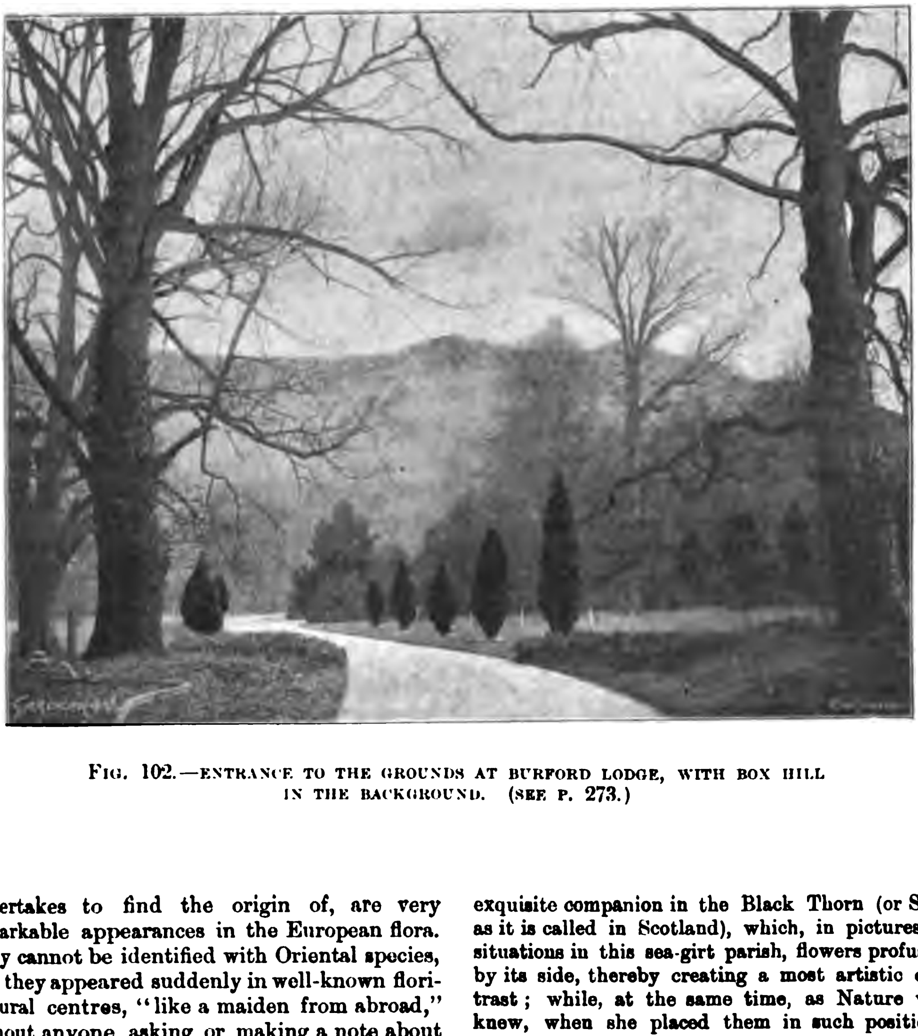

Fig. 102.—Entrance to the grounds at Burford Lodge, with Box Hill in the background. (See p. 273.)

NOTES FROM A SCOTTISH MANSE.

This season might expressly be called the period of Nature's transfiguration. Since last I wrote to the *Gardeners' Chronicle*, her aspect has undergone under the influence of more inspiring atmospheric conditions, a most marvellous change, and the trees at that period so bleak and naked in their outward appearance, though full of embryonic hope and capability, have assumed their tender and delicately-tinted leaves at the touch of the mighty magician of the spring. Primroses in millions make yellow the deep glens, or the green slopes above the shore. In the woodlands, Scilla nutans, one of the loveliest and most fragrant of the manifold gifts of early summer, is preparing the revelation of its luxuriant bloom. Nothing is more beautiful at present than the Gorse, so much admired by the great Linnæus, some of whose hues rival those of the Maréchal Niel Rose. It has an exquisite companion in the Black Thorn (or Sloe, as it is called in Scotland), which, in picturesque situations in this sea-girt parish, flowers profusely by its side, thereby creating a most artistic contrast; while, at the same time, as Nature well knew, when she placed them in such positions, their colours harmonise.

Our gardens are also at the present period supremely attractive. My only Almond tree, a very fine standard of graceful form, is a mass of blossoms, which are seen to most advantage from the upper windows of the manse. I was informed yesterday by a visitor to my garden, a native of Chili, that in South America its blossoms are pure white. The Early Rivers, Czar, and "Denniston Superb Green Gage" Plums are blooming superbly; so also are the Early Rivers and Black Eagle Cherries, which seldom fail to blossom well. I have, *mirabile dictu*, the Irish Peach-Apple (April 27) in flower. Its usual time of flowering at Waltham Cross, in Hertfordshire, is given by Mr. Wm. Paul, in his valuable work entitled *Contributions to Horticulture*, as May 1. Other varieties, such as the American Mother Apple and the Duchess of Oldenburg, are almost equally far advanced, and will soon be in bloom; the latter, which is greatly cultivated and much esteemed by my friend Mr. Thos. F. Rivers, of Sawbridgeworth, is one of the most valuable Apples in cultivation. The Beauty of Bath, though charming in colour, I have not found so entirely trustworthy, though elsewhere, I doubt not, it may have proved a greater success. It is possible that in my own garden it may not have found a congenial soil, but I fear its constitution is not very strong. A more vigorous variety is the Early Strawberry, which is also very ornamental, by reason of its rich complexion during the autumnal months.

Our gardens will soon reach the climax of their beauty, for there is nothing more beautiful within the realms of nature than the Apple-trees in perfect and glorious bloom. The exquisite season of Violas and Auriculas, precious alike for perfume and their capability of massive floral effect, has already begun. The Violas chiefly admired and cultivated here are almost wholly of the miniature, richly fragrant, profusely flowering, "Violetta" type. But I also grow several of the larger and older kinds, such as the Countess of Kintore, Iona, one of her most charming variations; Prince of Orange, Florizel (one of Dr. Stuart's finest introductions), the graceful white Duchess, and Countess of Wharncliffe. Mr. Wm. Cuthbertson's Blue Bedder, recently raised at Rothesay, is a great acquisition.

During last winter I added to my already extensive collection of Lilies, the two latest introductions from America and Japan, viz., the Burbank Lily, raised by the American hybridist of that name; and Lilium rubellum, described by Mr. Baker, of Kew, in the *Gardeners' Chronicle*, May 28, 1898, fig. 128; which, by reason of its deep pink colour and greater reliability (though the flowers, I believe, are considerably smaller), seems not unlikely eventually to supersede that older and more familiar Japanese variety, Lilium Krameri, of which the latter, as I know from long experience, is somewhat difficult to cultivate, and even when successful fails to generate offsets, and seldom lasts longer than two years. Lilium rubellum, in the opinion of Dr. Wallace of Colchester, has a more vigorous constitution than its beautiful predecessor, Lilium Krameri, and even when its bulbs are of very small dimensions, seldom fails to bloom. Its reliability, indeed, seems to be one of its most valuable characteristics. It should therefore prove an important addition to those floral treasures which have been introduced into our British gardens from the East, and from the West.

The new American hybrid, which might classically be styled Lilium Burbanki ×, is the result of a cross between two noble species, viz., the deeply fragrant, lilacy-white Lilium Washingtonianum, and the majestic Panther Lily of California, Lilium pardalinum. With such a highly distinguished parentage, it can hardly fail to prove an interesting production. Its colour is orange-yellow, spotted with maroon. *David R. Williamson.*

PLANT NOTES.

CRINUM BALFOURI.

This is the first of a batch of bulbs lately brought home by Dr. Henry O. Forbes from his recent expedition to the Island of Socotra, and presented to the Edinburgh Botanic Gardens. The plant bears an umbel of twenty-two flowers, strongly fragrant, the scape being about 20 inches high. Individually, the blooms are about 4 inches across, white with a tinge of pink, this colour also tipping the style and filaments. The leaves are said to be much shorter than those of most Crinums. The figure in *Bot. Mag.*, t. 6570, must have been prepared from a small specimen of this species brought home by Professor Balfour in 1880. Some of the bulk now to hand are 8 inches in diameter, and round in shape, the flowers appearing before the foliage. An intermediate temperature, such as that required for Begonia socotrana, should suit this plant, and it is certainly worthy a place in our greenhouses for its fragrance alone, which is sufficient to fill the house in which it is grown. *R. L. Harrow, Edinburgh.*

ABUTILON SAWITZII.

At the present time I have a batch of beautifully marked, symmetrically-formed plants of this new Abutilon in 5-inch pots. The height of these variegated-leaved plants, from the rim of the pots, ranges from 10 to 15 inches. They were struck from cuttings inserted last August, and have been grown in a warm temperate-house during the winter. They have not been pinched. I find if the leader be taken out, a number of thin weakly shoots are produced, and the contour of the plant is not nearly so fine as when grown naturally throughout. The variegation is equally good in the case of unstopped plants.

Small plants in 3-inch pots of this Abutilon are useful as "dot" plants upon the dinner-table, being particularly bright under artificial light. In well-grown specimens the white variegation largely predominates over the green colour in the foliage. I have not yet grown the plant under such cool treatment as variegated Abutilons are generally given, but it is evident that the temperature we have employed is a suitable one, although a cooler one may answer. I have a doubt if the plants would thrive in a temperature below 50°, for the variety is not nearly so robust as A. Thompsoni, A. vexillarium, and others. If A. Sawitzii could be utilised for bedding purposes as are those named, it would be a gem in the flower-garden, as it certainly is when used for decoration of rooms. The plant was distributed several years since by Messrs. Sander & Co., St. Albans. *H. T. Martin, Stoneleigh Abbey.*

SOUTH AFRICAN NOTES.

JOHANNESBURG.

JOHANNESBURG is situated in the heart of South Africa, 6000 feet above the sea-level, and very nearly in the same latitude as Delagoa Bay, the southern point of Madagascar and Brisbane. The maximum heat I have registered in six years has been 93°, and the minimum 20° Fahr., thermometer under a regulation shaded screen 4 feet from the ground in both cases. The winter and spring are dry and cold, summer and autumn wet and warm. The rainfall, which varies year by year a little above and below 28 inches, falls between the summer months of October and March; the remaining months are practically rainless. Rain often falls so heavily—I have registered 2·42 inches in one night—that a great portion rushes away, and is lost. We have many light showers, which, although they make a respectable contribution when carefully measured, yet in practice they aid vegetation very little, owing to the very rapid evaporation. Vast stores of water exist below the ground in many places at from 50 to 100 feet. These are being utilised now. On every Dutch farm a spring is to be found; and wherever the flat high veld breaks, descends into the valleys. The springs often flow with great strength. There are several within a radius of 50 miles from here which yield from 1,000,000 to 20,000,000 gallons of pure water daily.

Geographically, this town is exactly on the dividing ridge of the water-shed of South Africa, for close to where I am writing, on one side a spring discharges itself into the Limpopo, and so on to the Indian Ocean; on the other side, another spring flows into the Vaal River, and thence to the Atlantic. On the slopes below the hills the soil is a very deep, sandy, alluvial loam, in some places over 200 feet deep, resting on gravel and granite. Lower down in the valleys we come on a black loam, with pottery clay below. Ten years ago the site of the town was a grassy slope, dotted with dwarf Proteas and Acacias, with no outward sign of the gold which lay below. Our mines have increased to such an extent that the monthly yield is 400,000 ounces of gold, equal to £50,000 each day! The total value of the gold in our great reef is said to be £1,000,000,000 sterling, but the working costs are about 50 per cent. A very short note on the origin of this gold deposit, which is fast changing South Africa, may be admitted here.

Imagine ten thousand ages ago a very large inland, shallow, salt-water lake where I am now writing. The water of this lake was strongly charged with gold, which is nothing extraordinary, as all salt water contains gold in a slight degree. Gradually the lake dried up, and the gold, as fine as flour, sank into the sandy bed; one side of this dry lake-bed sank down some 5000 feet, leaving the edge of the opposite side standing up, and formed the main reef. Great changes took place; the valley where the lake was silted up with sand and shale and mud, brought down by a great river. Ages afterwards, forests of Tree-Ferns and giant mosses covered many parts of the Transvaal, and these being buried were converted into coal, without which it would have been practically impossible to work the mines of gold. Gold and coal alike lay buried deep below the ground, unseen and unsuspected, until the present age. *R. W. Adlam, Joubert Park, Johannesburg.*

(To be continued.)

THE ROSARY.

FORTUNE'S YELLOW AND SUNRISE.

SOME years ago, a provincial nurseryman introduced a Rose which he called "Beauty of Glazenwood;" it is a climbing Rose, of rambling habit, and a profuse bloomer, and after some time it was discovered to be an old friend called Fortune's Yellow. This Rose appears to have been introduced by Mr. Robert Fortune from China, and for some cause or other it was but little cultivated until it came into the possession of the nurseryman who sent it out into the world as Beauty of Glazenwood. It is very rich in colour, being deep yellow, and curiously flaked and striped with dark red, a combination which forcibly reminds one of the Austrian Copper.

Sunrise, is a beautiful "gain" of Mr. Piper's, of Uckfield; it is a brilliant orange-yellow flower, with the back of the petals rosy-pink, of excellent form, and very free-flowering. It was shown in fine condition at the Royal Horticultural Society's meeting on May 2.

PROSPECTS OF THE ROSE SEASON.

It is perhaps somewhat early to descant upon this subject, yet as bud-shoots begin to start forth, one is tempted to say something. There are two lines of thought which come into the Rose-grower's mind as he looks forward to the season's outcome, the first being in what condition shall we find our old-established favourites? and the second, what new varieties are likely to be added to our list? With regard to the first thought, I fear the prospect is not of the brightest. Of course, I am aware how circumstances vary in different localities, and what may be true of our South-eastern corner of England, may not be true of the West, Midlands and North.

On looking through my small collection of Roses, consisting of Hybrid Perpetuals, Hybrid Teas, and Teas, I find that the cold weather at the latter end of March most seriously affected them. We had as much as 12° of frost, and as the sap at that period was rising rapidly, it hit the Roses very hard; not only were the young shoots scalded, but the wood I had not pruned was injured. Nor was it a question whether I should prune hard or not, for the frost had already settled that, and I had to cut down pretty low to get rid of the injured wood. I found this was alike in all three classes; indeed, I fancy that the Teas are not so much injured as the H. P.'s. I am not alone in suffering this injury, for I have been talking lately with several Rose friends, and they have the same story to tell; but I have just received a letter from one of our champion Tea Rose growers in East Anglia, who says he does not think he ever saw such firm, stout wood as he has on his Teas this year. It must ever be remembered that it is the amateur who especially suffers in such cases, for the nurseryman, who has his various quarters in different aspects, and on many different stocks, is pretty sure in some way or other to partially escape.

There is little to be done now to ward off any loss, and we must hope that no further untoward circumstances may occur. The demand for Rose plants has been exceptionally large, and it is pleasant to know that our American cousins are our very good customers. I do not think there will be any diminution in the number of our exhibitors, but that many will come forward to take the place of those who, from one cause or another, may have left our ranks. Few persons are aware what a strain Rose exhibiting is to those who enter thoroughly into it. The exhibitions, it is true, occupy but three weeks; but what busy weeks these are!—travelling night and day, snatching a hasty meal whenever it can be had, at the risk of indigestion; sleeping in uneasy positions in railway-carriages, and arriving at stations at unearthly hours, what wonder is it that the most enthusiastic exhibitors, after a few years, grow tired, and thus one after another we have seen our most prominent men throwing up the sponge. "No thank you," when one asked the question "Won't you exhibit again?" "No, thank you, I have had enough of it." So changes are taking place, especially among our largest exhibitors. *Wild Rose.*

VEGETABLES.

FRENCH BEANS: VEITCH'S EARLY FAVOURITE AND SUTTON'S MAGNUM BONUM.

WHERE a succession of dwarf Beans is required through the winter and spring, the above varieties are very useful to follow the pot varieties, such as Sion House, Osborn's Prolific, Mohawk or Six Weeks, and Ne Plus Ultra.

We sowed Early Favourite at the end of January in a bed in a span-roofed house, with little or no fire-heat, and have been gathering Beans for the last month. These have been abundant, and of splendid flavour and quality; they promise to give a good supply for some time to come. Magnum Bonum was sown in the same house three weeks later, and is just swelling-off the first fruits. This variety has grown some 8 or 9 inches taller than Early Favourite, and the pods are of excellent length and substance. These varieties require to be sown very thinly, and to be given restricted root-room, as they are very robust-growing, and are liable to damp if the temperature be too low when the flowers are setting. One of the best manures for French Beans is sheep-droppings. *A. B. Wadds, Paddockhurst Gardens, Sussex.*

SPONTANEOUS HYBRIDS OF HARDY PLANTS.

(Concluded from p. 260.)

AMONGST garden forms of perennial Sunflowers, it is often difficult to fix the type of the species, still more to recognise the parents of the hybrid forms. I have found so much uncertainty about the names, that I believe some of the best and commonest forms are hybrids, perhaps between Helianthus rigidus (a very broad name) and H. doronicoides; but I feel no doubt that many of the allied species readily form hybrids, and that many of these hybrids retain their fertility, producing a variable offspring. In annual Sunflowers, a friend once sent me ten seeds, saved from a handsome hybrid plant, obviously between H. annuus and H. debilis var. cucumerifolius. These seeds all grew, and divided themselves fairly between the parents, five belonging to each type. This year, Mr. Lynch, of Cambridge, has sent me seeds of a hybrid between H. annuus and H. argophyllus; they are already up, and will probably revert in a similar way.

Like the Sunflowers, the North American Asters make many hybrids, which are often for the same reasons hard to recognise. Sometimes, however, they are well marked, as when the plumes of small flowers of A. cordifolius have to make a compromise with the large flowers and lanceolate leaves of A. lævis or A. novi-Belgii. In both these cases the result is good in making distinct and ornamental varieties. Other excellent garden forms, such as W. J. Grant, and Coombe Fishacre, are certainly hybrids of uncertain parentage. No definite rule can be laid down as to their fertility. Some make good seed, and I have found that in Aster it is never safe to pronounce seed barren without a fair trial. The European Aster Amellus presumably was the pollen-parent of the best hybrid Aster which ever came in Edge garden, the seed-parent being the Himalayan A. Thomsoni. It is almost a complete inversion, the flower and habit being very near A. Amellus. It is the only one of the kind I have seen, and by careful division I have raised and distributed several plants. Its chief merit is its very long flowering season, lasting from July to October. Another hybrid which goes on being produced from the same plant of A. Thomsoni every year, sowing itself near the parent, is between that species and A. pyrenæus, which grows all round it. The flowers are always intermediate, especially in the form of the pappus, but vary in merit, being only in a few cases better than either parent.

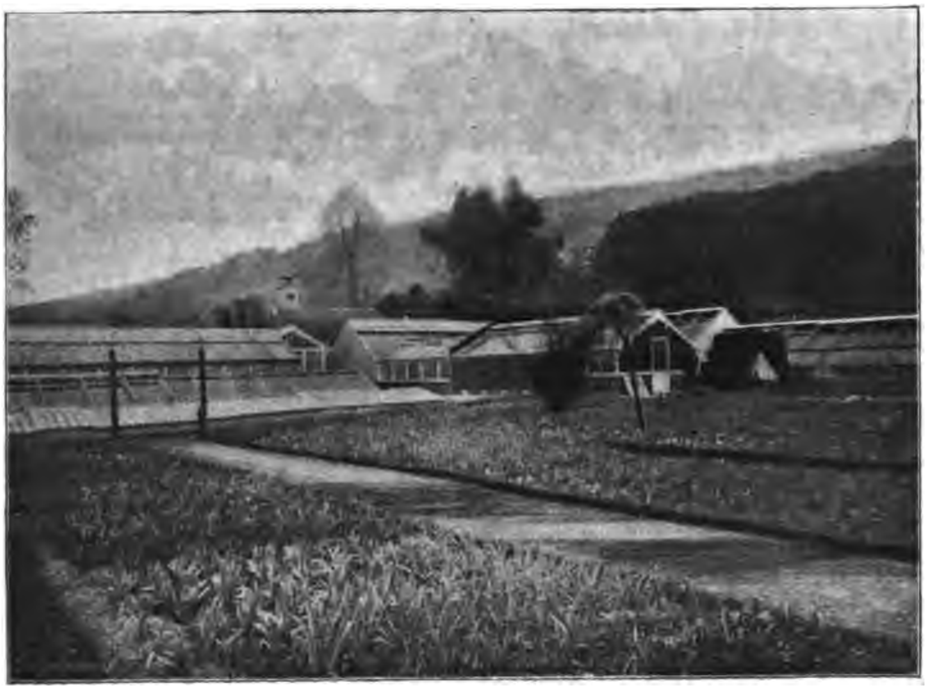

FIG. 103.—SOME OF THE HOUSES IN THE GARDENS AT BURFORD LODGE, DORKING. (SEE P. 273.)

Heuchera sanguinea forms hybrids freely. The first I noticed was six years ago, when a plant growing by the side of the parent produced pale pink flowers. On examination these proved to be evidently a cross with H. cylindrica, which grew near. The hybrid ripened a little seed, which grew and flowered, some being darker than the hybrid parent, others nearly white. They have no new merit, but are a curious nondescript set. About the same time near other plants of H. sanguinea, I noticed two plants with the brown shiny leaves of H. hispida (syn. Richardsoni), these produced loose panicles of pale pink flowers and ripened seed, which I believe I have sown, but I can hardly call them interesting, so pay little attention to them. I think I have seen a similar hybrid offered in nurseries as H. brizoides. If the two hybrids I have described have any merit, it is in being much more hardy and more free flowering than the seed parent. The frosts at the end of last March have nearly destroyed H. sanguinea in exposed parts of the garden, but the hybrids are unhurt.

I may mention a very pretty and elegant hybrid, unfortunately not robust, but now flowering for the third season, Ranunculus amplexicaulis × R. gramineus, leaves and flowers, in colour and form, are honestly intermediate. It produces a few seeds, and three or four seedlings will soon flower. Malva Alcea and M. moschata, both pink and white, seem to coalesce into a mixed lot, which I am unable to discriminate, though I admit that I do not judge by any definite characters.

Herbaceous Veronicas are very erratic in their characters when grown from cultivated seed. The tiny wild native V. spicata soon passes into forms 2 feet high. One of them produced a very handsome hybrid with V. incana, of which I accidentally came across an exact portrait in Sweet's *English Flower Garden*, named V. neglecta, which no doubt had the same origin. Also the very distinct form of V. virginica, called in nurseries V. sibirica, crosses spontaneously with the type, forming tall, straight spikes of pale purple, better than either parent.

I must not close the subject without speaking of one more hybrid—Lychnis coronaria × L. Flos-Jovis. This came, I believe, spontaneously, many years ago in the town-garden at Chester of my friend, Mr. A. O. Walker, who gave it to me. It is exceedingly robust, growing from any scrap, even although rootless. It has a very prolonged flowering period, and produces a few seeds which I have never taken the trouble to test. The colour, however, being magenta-crimson is proscribed by artists; and if by a few renewed trials of the same cross the hybrid could be produced with the pure pink flowers of L. Flos-Jovis, it would make a valuable decorative-plant. *C. Wolley Dod, Edge Hall, Malpas.*

THE LILIES OF THE SIERRA NEVADA.

LILIUM PARDALINUM, Kellogg. — The excessive dryness of the Sierra foot-hills drives this moisture-loving Lily into the cañons and ravines. Even there in places where it was once plentiful, and gathered in magnificent bunches by those arriving in the "days of '49," it has become rarer and rarer, till now we have to climb amongst rocks and dig in deep deposits of loam to secure this bright Tiger Lily. I have found its stalks as high as 6 feet, nodding over precipices, or standing upright and displaying from one to six or seven flowers. Wherever found, it inhabits bright, sunny spots, and delights us by its fresh and clear colour of orange, often washed with deep brownish-red. The spots of deep maroon are very thick (and yet distinct from each other) on a lighter ground-colour of orange.

Thus distributed, I have found L. pardalinum from 1000 feet up to 4000 feet. At the latter elevation, one begins to find sub-alpine meadows. While the brightness of colour, the density of the herbaceous growth, and the deliciousness of the perfume of these meadows have become proverbial. I remember, with double freshness, one especially of the many I have traversed. This one was a meeting-place for the Indians as they traversed the Sierra from California to Carson Valley, in the State of Nevada. They call it "Sopago," deriving the name from the so-called Soaproot, Chlorogalum angustifolium. Here, surrounded by the high ridge of the mountain chain on which the emigrant-road runs, moist on account of its position on the north slope, stretches a wide vale under the shelter of giant Pines and Firs, which are safe from the murderous axe on account of their inaccessibility. Scattered settlers have set up homesteads here and there, and in the cleared areas, where their garden and grain plants ripen into rich crops in the deep, loose, blackish soil, was the largest field of Lilium pardalinum I ever beheld. What a stand of Lilies! They grew in thickets, stem by stem like grass in the meadow, 4 feet high, all with nodding heads of from four to seven flowers. Standing in the opening as they did, their colour was clearer (more orange), and the foliage shorter, and the stem more robust. Contrary to common belief, I was surprised to learn that the disturbance of the ploughshare rather favours than hinders the growth of the Lily, its corms dividing into fragments, each of which produces a new plant if but half covered by the rich warm soil under a sky the clearness and brightness of which render everything in its sphere grand and delightful.

Lilium Humboldti is another so-called Tiger Lily, of more sturdy growth and majestic character, the "Pardalinum of the hillsides." It occurs at about 2000 feet elevation, always selecting the open Pine-woods, never found near water, but always preferring slopes facing north. In this region, all the old timber growth has been cut off, and as we drive along the roads we may see the bright bunches, made up of five to twenty-five flowers on a stalk, shining brightly through the thin boughs of Pines. As the Hazel-nut is the steady companion of L. pardalinum, so the cream-coloured Iris Hartwegi is always to be found where Lilium Humboldti abounds. Two causes render this Lily more and more scarce: the stand of even the second growth of Pines is being cleared away and replaced by grain fields; in the second place, this species, wherever it occurs, is found in such thick growths as to invite the settler to supply his garden with Lilies from the fields. Lastly, it may be said that it requires fully three seasons for Lilium Humboldti to bloom again if it is once disturbed, and, unlike L. pardalinum, the ploughshare is its sure death.

Lilium parvum, Kellogg.—As its name indicates, the flowers are small; their colour is orange, with spots on the inside of the petals. It belongs to the alpine region, reaching as high as 8500 feet in the region I traversed, and does not occur below 4500 feet. Wherever I found this Lily, I noticed two forms, neither of which approached the other in any intermediate specimens. The smaller one reaches a height of 4 feet; its build is light, and upon the stem, set with scattered leaves of light green, stand loosely from two to six or seven flowers. The other kind is a giant in stature and make-up; the stems are woody and hard, set with whorls of rich deep green foliage, and carrying heads with from twenty to fifty flowers. I did not notice any difference in the flowers, and while it may be possible that this giant is nothing but a "Sequoia" amongst its kind, it is plain that the two varieties are widely different in appearance.

Lilium Washingtonianum, Kell.—High upon the ridges, exposed to storms from east and west, in soil of scantness, and dry almost as the granite from which it derives its existence, there grows the queen of the Lilies of the Sierras, L. Washingtonianum. Bands of sheep and cattle trot by on their way to the sweet meadows of the alpine region, and no herb, no limb of recent growth may be detected other than the bitter-barked Aspen or the prickly Snowbrush. I write of the ridge of the spurs bridging from the foot-hills to the snow-fields, as it appears in July. Under the shelter of the impenetrable Snowbrush, Ceanothus cordulatus, this Lily begins its growth at the time that the first bands of sheep start for the mountains. After the "hoofed locusts" have passed, and quietness again reigns on the ridge, interrupted only by the clatter of the horses' hoofs as the stockmen go back and forth to their ranges, then this Lily stretches its stately head from under the Thorns, and develops its fragrant flowers in the first week of August. They are white; and while I have been told about spotted ones—so spotted, in fact, as to be entirely set with rich maroon on the inside of their petals—I know them from the Sierra of Amador and alpine counties only with very tiny spots, and such tiny spots I have found on flowers only now and then. But the plants are grand in their stand, their tall stalks as high as 5 to 7 feet, and hanging out to the gentle breeze from two to twelve flowers. Emigrants passed along the ridge I mention for years and years, stockmen followed them, and bands of cattle made this region their home ever after; therefore, it is likely that this Lily may have been much more common in early days than now. Be that as it may, the plants I encountered are well protected from any attack by man or beast; and as we follow along the ridge, where the water must be packed for as many as twelve miles of travel, there holds guard this stately flower of our Sierras, delighting all as they pass either on their way to the valleys where the Lilium pardalinum is scattered about the winter homes of the settlers, or to where the ring of a hundred bells from the sleek necks of cattle add charm to the region where the tiny Lilium parvum grows along streams and precipices. *Geo. Hansen in "Erythea."*

SCOTLAND.

FORESTRY AS A PROFESSION FOR THE NATIVES OF INDIA, &c.

The Edinburgh University has recently been favoured by three lectures by Sir Dietrich Brandis, Ex-Inspector-General of the Forests of India, on the former subject, delivered in the Conveyancing Class-room of the University; these lectures were of the most instructive character as to the area, vital importance, and mode of managing our Indian forests.

The forestry estates cover some fifty million acres, while the duties of the Civil Service extend over 616 million acres, or 965,000 square miles. The Indian Empire, like others, is divided into provinces. Including the two Presidencies of Madras and Bombay, India is divided into eight large provinces and five smaller ones; in the whole there are 234 civil districts, each under a district officer, sometimes called a collector, at others a district commissioner. Besides these, there are a variety of other appointments—commissioners of divisions, settlement officers, and secretaries. These appointments in all numbering 824, are held by members of the Covenanted Indian Civil Service. Dr. Brandis spoke in the highest terms of the management of the forests, and the wisdom and prudence of the Government. Some of the fruits of the Civil Service Commission in 1886 were the raising of the age of candidates at the open examination held in London. During the five years from 1894 to 1898 inclusive, out of a total of 383 successful candidates, only thirty were natives of India.

The commission also advised the division of the Civil Service into three great branches—the judicial, the provincial, and the subordinate service. He pointed out that the officers in charge of such sub-divisions of districts as Myokir, Sahisdara, were unfortunately classed as subordinate officers. This was not the right position for an officer responsible for the government of 600 square miles, with a population of three and a half millions.

Contrasting the organisation of the public service in India with that of Germany, the lecturer made a strong appeal in favour of getting the highest classes of native Indians to take a more prominent part in the development and better management of the forests, concluding a series of stimulating and instructive lectures with the wise words of Lord Roberts in the House of Commons to the effect, "that the key to India is not to be sought for at Herat or Kandahar. It is to be found in the prosperity and contentment of the people. The blessings of progress which will become greater when the natives are more closely identified with the Government and forest management in India. Upon the wise solution of this question largely depends the maintenance of the British Empire in India." *D. T. F.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Cattleya Lawrenceana, now in bloom, is somewhat difficult of cultivation. Give water sparingly until root action is established. C. Lawrenceana being native to a low tropical region, the plants should be placed in the East Indian-house just before making their growths, and when this is completed they may be returned to the warm end of the Cattleya-house.

Dendrobium Falconeri—The cultural treatment frequently afforded this Dendrobium tends to encourage growth rather than a free-flowering habit. At the present season it is possible to obtain imported clumps, which should be immediately fixed in small pans or baskets, allowing the much-branched pseudo-bulbs to be pendent, and only using just sufficient peat and sphagnum-moss to cover the drainage. When this has been done, suspend the plants in a light and airy position in the Cattleya-house, and syringe them daily. After many roots have been made it is good practice to dip the plants bodily in the water-tank for a short time every morning until growth has ceased. Watering after this must be done more sparingly until in winter the plants will only need sufficient to maintain the pseudo-bulbs in a plump condition. D. × Venus, a hybrid from D. Falconeri, requires very similar treatment, but I would not dip this plant at any season of the year.

Cochlioda Roezliana may be grown in baskets or pans, with a rooting medium of peat and sphagnum-moss, the best position for them being above the Masdevallias, where they should be suspended. Any surfacing the plants may require should be done at once. They grow freely during the summer, and require at that season a goodly supply of water, which afterwards must be much decreased. C. rosea, C. vulcanica, and C. v. grandiflora are best grown in pots in company with Odontoglossum crispum.

Palumbina Candida.—This quaint-flowered plant now requires attention; it is best grown in pots or pans, and owing to the downward tendency of the rhizomes, the plants should be raised considerably above the rim of the receptacles. A moist, shady position at the warm end of the cool-house suits it best. Water sparingly, except during active growth.

Remarks on Temperatures, &c.—The following are suitable (shade) temperatures for the various structures. East Indian-house 75° by day, receding to 68° in the early morning. Cattleya-house 68° by day, falling to 63° by morning. The cool and intermediate-houses will now need very little fire-heat to maintain the requisite degree of warmth. Each house will need a thorough damping down every morning so soon as the temperatures have risen a few points, and in most cases again in the afternoon, but for some time yet this will depend on outside conditions. The warm-houses should become comparatively dry for a time about noon each day, but the cooler ones may be always given abundance of moisture, because the circulation of air in them is greater. The East Indian-house may be shut up early in the afternoon, but the others will require abundant ventilation during the day, and some also at night. The quantity afforded at any particular time must depend upon the conditions of the weather. Ventilation should be admitted from the sheltered side of a house during the prevalence of winds.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

The Early Peach-house.—Where the custom obtains of allowing Peaches to become perfectly ripe upon the trees, it will be necessary to employ fish-nets, or a good layer of clean straw spread over the floor, to prevent damage to any that may fall. The nets should be suspended from a convenient overhead position, and fastened to the trellises at the base of the trees. No such precautions are necessary, however, if the gardener makes a point of examining the ripening fruits regularly, and removing those sufficiently matured to the fruit-room. A gentle pressure by the forefinger applied to the fruit near the stem will determine the state of ripeness; and Peaches gathered before they are dead ripe, and stood in a cool room for a few days, are better in flavour and superior in every way to those that are permitted to remain upon the trees until they fall. But the greatest care is needful in the handling of Peaches, particularly if they have to be despatched a distance, as they are extremely liable to be blackened by bruises. Syringing of the trees must be discontinued when the fruits commence to soften, but the borders must still be daily damped down, and regularly afforded the necessary root-waterings. The ripening of the fruits will be hurried and premature if the roots be permitted to lack moisture. If the temperature of the house be slightly lower at the time of fruit-gathering, the trees will be benefited, and the altered condition will tend to increased quality in the fruits. A little ventilation may be afforded at night when the weather is mild.

In the Second Peach-house the fruits will be passing through the stoning period, a time when severe forcing is extremely hurtful. Weakly trees, whether from age or over-bearing, will need stimulating food, which may be furnished by a dredging of dry chemical manures, or natural liquid-manures obtained from the cow-yard or stable, diluted according to its strength. In all cases it must be carefully ascertained if the borders contain the degree of moisture necessary to the trees. Do not neglect to syringe the trees daily, for if red-spider get a foothold, it is not an easy matter to effectually dislodge them. Tie the new growths in position, and expose the fruits to all the sunshine possible. Do not permit the growths to become crowded. If there be not sufficient space for them, either pinch out their points, or remove them altogether. Very strong shoots may be pinched, afterwards tying-in the best-placed lateral growths that result from the stopping. In the case of well-furnished trees, the better plan is to remove these vigorous growths altogether. If green-fly be noticed, fumigate the trees, or syringe them with an insecticide.

Successional Houses.—The temperature and conditions necessary to trees in later houses will depend on circumstances, and the period when their fruits will be required. In gardens where a good supply can be obtained from out-of-door walls in August and September, the crops in the Peach-houses may be arranged to ripen at other times. Late varieties that may be expected to ripen in September and October should be kept as cool as circumstances permit, for the later that Peaches and Nectarines may be had in October the better. In the late house, thinning of the fruits should be done with considerable care. It is not advisable to reduce the crop to an average one until it can be seen with certainty which fruits are perfectly set. Thin out the shoots to the number required to furnish the trellis. Aphides, which in cool-houses are often troublesome at this stage, must be attacked before the leaves have become badly curled.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

The Disbudding of Fruit-trees should be continued at short intervals until all unnecessary growths have been removed. As Peaches and Nectarines are earliest among wall-fruits in starting into growth, most of the surplus shoots have probably been removed. Stop any extra strong-growing shoots, and retain one or more that will start from the base of such as are stopped.

Apricots.—When continuing to disbud these, take care to reserve any conveniently-placed growths on the front of the branches for the formation of spurs, as the Apricot fruits freely on spurs, as well as on wood of the previous year's growth. In addition to these, and besides the growths on the points of the shoots, one at the base of each should be allowed to remain. Take away a few of the others, at intervals of a few days, until the work is completed. Where any signs of loss of shoots are apparent from gumming or other causes, a sufficiency of young growths should be retained, to fill up eventually the space that will thus become vacant.

Sweet Cherries, Plums, and Pears, should be treated in a somewhat similar manner, removing the weakest and worst-placed growths, and retaining only sufficient to fill the spaces without overcrowding. The points of shoots that have already filled their allotted space should be stopped at the second or third leaf.

Out-of-door Vines.—Remove surplus growths, and leave one shoot only to each foot of rod.

Thinning Pear-blossom.—In the majority of gardens Pear-trees are blooming most profusely, and in such cases the blooms will need to be thinned. Weakly trusses may be removed altogether, and others thinned down to two or three fruits, retaining those that are the strongest and best placed.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Chrysanthemums.—The early-flowering varieties may now be planted out. They succeed best when planted on a south border, and if mixed with other plants, a sunny position will be necessary, as the stems require to become well matured to produce good flowers. Ordinary garden soil will be found rich enough for them. A distance of 3 feet should be allowed between each plant. Ryecroft Glory, Yellow Lady Selborne, Yellow L'ami Condorchet, Fiberta, Golden Madame Desgranges, Mrs. Hawkins, and Golden Drop, are the best of the yellows ; Mychett White, extra fine ; Madame Desgranges, La Neige, Sœur Melaine, St. Marie Vierge, excellent whites ; Captain Webb, Early Blush, St. Croutts, Trevenna, pinks ; Captain Nemo, Anastachio, Adrastes, Madame Picoul, Mons. Bredenner, purples ; Mons. Hoste, Mons. Wm. Holmes, Précocité (very fine), Souvenir de Madame Menier, Jules Lagravère, Mons. Henri Jacotot, Mons. Maxime de la Rocheterie, crimsons.

Roses.—If aphis has made an appearance on the young growths of the Roses, obtain some extract of Quassia, dilute it with water, and spray them, thoroughly wetting both sides of the leaves. This will destroy the flies, and leave afterwards a bitterness that is objectionable to them. Tobacco-powder is also an effective remedy. If any of the leaves be curled, they will probably be found to contain a maggot, which should be squeezed between the thumb and finger. Rose-trees that were not top-dressed in the autumn, and show signs of weakly growth, should be given about a quarter of a pound of dissolved bones to a square yard of soil; afterwards giving the roots a thorough watering.

Hollies.—May is the best time to transplant species of Hollies. First select a position, and make a hole large enough to take the ball ; then move the specimen, and lay out the roots in a natural position, adding to them as the work proceeds some fine leaf-mould or peat. When the work has been completed, afford a good watering to settle the soil among the roots, and finally mulch the surface with stable-manure. Seedlings from two to three years old that have been raised in beds in the nursery should be transplanted, 18 in. from plant to plant, and in rows 2 feet apart. It is always best to keep smaller plants of the varieties growing on, especially the golden and silver variegated kinds, as some years must pass before they become good specimens. The male and female (monœcious) flowering varieties are the most compact in habit ; the hermaphrodite flowering varieties, if not kept continually cut back, soon grow woody, and the branches near the stem become bare of foliage. All Hollies produce much better foliage, and become more dense, if pruned just before making new growth. Any bushes that have been neglected should be cut well back, as they will soon grow from the end of the cut, and invariably break further back in the stem.

Ivy growing against buildings or on walls should now be clipped back ; young leaves will soon grow, and if kept close in this manner, the Ivy will not be blown away from the wall by the wind, or weighed down in winter by snow.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Beet.—The main crop should now be sown, unless there be a doubt that the roots may grow larger than wished. If this be the case it will be better to sow one half now, and the remainder after a fortnight. Cheltenham Green-Top is a finely flavoured variety, and is less attacked by sparrows than the leaves of the darker coloured kinds. Varieties of Beet are very numerous, but Dell's Crimson, Pragnell's Exhibition, Cheltenham Green-Top, and Egyptian Turnip Rooted are still favourites. The ground for this crop should be deeply worked and brought into fine tilth. If it be too poor the roots will be ill-shaped and inferior in quality, but it should not be more than moderately rich. Sow the seeds thinly in drills 18 inches apart and 2 inches deep, and do not allow the young plants to grow too large before they are thinned out to 8 inches apart. Young plants of the Turnip Rooted variety just above the ground should be repeatedly dusted with soot and ashes to preserve them from sparrows and slugs. When living in Kent, I made use of the sweepings from the hop-kilns, and found it to answer first-rate for this purpose.

French Beans.—Sow a few rows upon a warm border, putting the seeds 8 inches distant one from the other, and the rows 14 inches asunder. Make the drills about 3 inches deep, and plant only the earlier varieties such as Ne Plus Ultra, and Pale Dun. This being a chance crop, another sowing should be made about the middle of the month, and they may be fit for use at the same time as those sown now. French Beans may also be sown in pots, and encouraged under glass. They can then be planted out at the foot of a south wall, or on a well-sheltered border, when the plants have become a foot in height. From such plants good gatherings of tender pods may be had several days in advance of those sown outside.

Scarlet Runner Beans.—The trenches should be prepared in readiness for sowing Runner Beans. Make the trenches similar to those intended for Celery, with the exception that more manure may be dug in. When digging out the trenches, replace the bottom soil with the top spit. For many years I have sown the first batch of Scarlet Runner Beans about May 14.

Early Brussels Sprouts.—Plants raised from seeds sown at the same time as Early Cauliflowers will now be large enough to be planted out in the open. Select a good piece of land, that has been either trenched or deeply dug ; draw the drills 4 inches deep and 3 feet apart from each other. The plants should be 2 feet asunder in the rows. Lift the plants with care, and do not expose them long to the air. If the ground be subject to grub, or the plants are likely to club, give a good dressing with soot, and when the plants have been put out, to settle the soil about the root, give a good soaking with soot-water. Repeat this at intervals. It is said that water containing a little dissolved salt is a good preventative, but this should be used with care.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Bougainvillea glabra should be repotted when the young shoots have become 2 or 3 inches in length. Let the pots be sufficiently large to admit of an inch of new soil being worked around the roots. The compost may consist of three parts loam, one part peat or leaf-soil, and plenty of coarse silver-sand. After potting, the plants should be placed in a brisk heat for a short time to encourage root action, after which they may be transferred to an intermediate-house or warm greenhouse. Except in the case of newly-potted plants, shading should not be given. In cases where the plants have made new growths very thickly, overcrowding should be prevented by the early removal of the weaker shoots.

Cytisus racemosa.—As these plants pass out of flower, cut them back and place them in a house having a warm, moist atmosphere ; and when they have started into new growth, repot them, using a compost of loam, a little leaf-soil or peat, and sand. As the growth progresses, the amount of air should be increased ; and upon the completion of the growth, the plants may be stood out of doors.

Reinwardtia (Linum) trigynum and R. tetragynum.—Cuttings of these very showy yellow winter-flowering plants may be inserted in pots filled with sandy soil, and plunged in a hot-bed or propagating-frame. When rooted, they should be potted-off into small pots, and grown on in an intermediate temperature until the summer, when they may be transferred to a cold pit or frame. The plants should be freely syringed, in order to keep down red-spider. Three parts fibrous loam with a little leaf-soil and some silver-sand is a suitable compost in which to grow Reinwardtias, and 5-inch or 6-inch pots are large enough to use for the final potting.

Miscellaneous.—Do not unduly hurry Lilium speciosum and L. auratum. Introduce bulbs into a cool house for a succession of flowers. Keep the plants free from green-fly by dipping them in an insecticide, or by fumigating them. Repot Justicias into larger pots sufficiently early to prevent them from flowering prematurely ; and pinch out the points of these plants, and of Ruellias, Impatiens, Bouvardias, Heliotropes, &c.

THE APIARY.

By Expert.

Artificial Pollen.—If the weather becomes warm, pollen should be freely gathered now, and failing a natural supply, Pea-flour may be given in its stead. For inducing bees to take Pea-flour nothing excels an old skep, from which the combs have been cut out. After being warmed at the fire, its odour will attract the bees to it very soon, and they will take the flour—scattered on shavings—at a great rate.

Weak Stocks.—The result of the first spring overhauling may reveal the fact that some stocks of bees known to be badly provided with food last back end will now be dead, or will have become so reduced in numbers as to be still broodless, with less than a pint of bees in the hive. It is useless tinkering with such stocks singly, they cannot be made strong in time to be of much use, and therefore, two or more of them must be united by the method usually adopted.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	May 9	Royal Horticultural Society of Ireland, Meeting.
FRIDAY,	May 12	—Royal Botanic Society, Lecture.
SATURDAY,	May 13	—Royal Botanic Society, Meeting.

SALES.

TUESDAY,	May 9	Important Sale of Established Orchids, at Millbank, Wilderspool, Warrington, by order of Mr. W. Bolton, by Protheroe & Morris (two days).
WEDNESDAY,	May 10	Japanese and English-grown Lilies, Gladioli, Greenhouse Palms, Begonias, &c., at Protheroe & Morris' Rooms.
FRIDAY,	May 12	Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period April 23 to April 29, 1899. Height above sea-level 24 feet.

Remarks.—The weather for the past week has been remarkable for cold rains and winds, with bright sunshine at rare intervals.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—53·2°.

Actual Temperatures:—

London.—*May* 3 (12 P.M.): Max. 56°; Min. 54°.

Provinces.—*May* 3 (6 P.M.): Max. 58°; Min. 43°, Shetland.

Diseased Malmaison Carnations.

It is not a little remarkable that the two diseases which are so disastrous to Malmaison Carnations, and the cause of so great annoyance to growers, should vary so greatly in their effects on plants cultivated respectively in the south of England and in Scotland. In the latter country the fungoid growth called Helminthosporium echinulatum, which, vegetating inside the Carnation leaf, and bursting the epidermis, reveals itself in dark-brown powdery spots, and which is so destructive to plants in south Britain, is comparatively unknown. We believe it is a fact that few who cultivate Malmaisons in the north have ever had practical experience of this disease.

Equally remarkable are the effects resulting from the presence of the Carnation eel-worm, Tylenchus, while southron growers are able to make light of its presence in the north, its appearance is always dreaded, because at any moment it may assume a form so virulent as to lead to the destruction of whole stocks, and even healthy-looking layers may become incapable of producing roots. It is least destructive in its effects in the case of the pink variety, exerts an influence a little more baneful on the original blush; while its dealings with Lady Middleton, the striped form, is at once treacherous and fatal, inasmuch as plants in the flush of health during summer may long previous to winter be fit only for cremation. There are some who declare that no stock of Malmaisons, however healthy in appearance, is possessed of immunity from the attack of eel-worm. At the same time, it is just a little suspicious that plants bought and sold as free from disease can seldom, if ever, be depended upon to remain so for any length of time.

It will be gathered from the above remarks that Malmaison disease, as referred to in the southern parts of these islands, and also, we believe, in Ireland, is an organism different from that spoken of in the north. The former is in a degree amenable to such treatment as washing continually repeated, or to the application of fungicides. The latter, so far, has resisted successfully all attempts to destroy it unless its host is also sacrificed. The drastic measure of destroying infected stocks to be replaced subsequently by healthy plants, has often, indeed, been recommended, but it has certain drawbacks, not the least formidable of which is the undoubted uncertainty of being able to introduce disease-free plants in the room of those destroyed. So long, therefore, as it is possible to keep plants in a condition fairly healthy by means of annual renewal from layers, it would be unwise to go to extreme lengths.

Gardeners might take a hint from the market-growers who occasionally infuse new blood into their stock by purchasing from their neighbours; and also, say every second or third year, introduce a lesser or greater number of plants from a source reputedly healthy, and as far as possible propagate only from these. Bought-in Carnations, as a rule, do better for at least a couple of years than plants from home-layers. The condition of the layers, or rather the quality of the layers themselves, is a matter of no slight importance. One thing is quite clear, that badly-infected plants should not be propagated. As soon as these are bloomed-out it will always prove true wisdom to burn them. Very strong layers are, again, less to be depended on than those which, while healthy, are by no means so vigorous. And of these, short layers are better than long ones, for it is a curious habit of the eel-worm that it prefers old leaves to lodge in, and therefore even in the case of plants knowingly infected it is possible to secure, by taking short tips, fairly good layers. Early-layering is also a commendable practice, and one that is worth while to make an unvarying part of routine management

The treatment of the plants has an undoubted effect on the nematoid. Because, just as it seems to prefer a leaf that has been in existence for a prolonged period, so does it multiply most rapidly in plants that from any cause have experienced a check to growth. The check, for example, may arise from overwatering, or from a condition of an opposite nature during hot weather; from being too much shaded in winter or spring; or later, from being exposed to strong sunshine. It is also known to propagate rapidly subsequent to yearling plants being potted-on for blooming a second year. To escape this danger, growers have the plants repotted from 5 to 8-inch pots in spring, a practice that can be recommended only where the most careful watering is subsequently followed.

There is further the question of what material is best to use as a compost. It is well known that eel-worm finds a congenial home in Grasses, and in order to destroy the organism in turf, it is only prudent to bake it previous to mixing it in composts for Malmaisons. In any case, the turf ought to lie at least six months before using. The siftings from Orchid peat is a safe material to lighten loam, and these, with the addition of sand, to keep the compost open, is all that need be employed. Dung is unnecessary, and is better left out.

A simple unmanured compost like the above must, of course, be supplemented during the growth of the plants by an efficient fertilising agent. Manure-water, prepared from animal matter, should not be used; nor any fertiliser in a dry state, about which there is a suspicion that it may contain blood or other animal matter. Soot is valuable, though slow in action. But, on the whole, there is perhaps no better food than a mixture composed of dry superphosphate of lime three parts, and sulphate of ammonia one and a half to two parts; a little of this applied at weekly or fortnightly intervals to the surface of the soil is at once effective, and perfectly safe.

Owing, no doubt, to the wet, dull weather in the early part of winter, "spot" (Uredo dianthis) has been present on Malmaisons to an unusual extent this season in the north. This disease is easy of control if a dry, airy pit is at command, and infected leaves or even portions of leaves removed as the disease appears. By spring, collections ought to have been cleared of the pest. The past winter's experience points to the danger of keeping Malmaisons too long in frames; and perhaps, as a rule, they would always be better to be treated as greenhouse plants.

Linnean Society of London (April 20, 1899). Dr. A. Günther, F.R.S., President, in the chair.—Mr. J. B. Carruthers, F.L.S., communicated some observations on the localised nature of the parental characters in hybrid fruits of Theobroma Cacao, on which some criticism was offered by Rev. G. Henslow. Mr. H. H. W. Pearson, B.A., read a paper on the "Botany of the Ceylon 'Patanas,'" large savannahs in the forests at the same sub-tropical levels, and with the same climate, though not peculiar to Ceylon. These "patanas" appear to maintain their limits for long periods; but whether they thus exist on account of the burning of the grass in autumn, or by reason of some peculiarity in the climate, or exposure, is a question on which some difference of opinion has been expressed. The Rev. O. Pickard Cambridge, M.A., F.R.S., communicated a new list of British and Irish spiders. After reviewing the existing literature on the subject, and the materials which had come to hand since 1881 for a new and revised list of species, the author pointed out that the present paper was not intended merely for the use of authors or collectors interested in local faunas, but to give (with reference to primary authorities) the spiders at present known to belong to Great Britain and Ireland, leaving the question of their distribution, abundance, or scarcity, to be dealt with at some future time, when the present scanty number of spider-collectors might have increased. At present, large areas of varied natural characters, in some cases whole counties, and many maritime districts, were entirely unexplored, so far as the Arachnology is concerned.

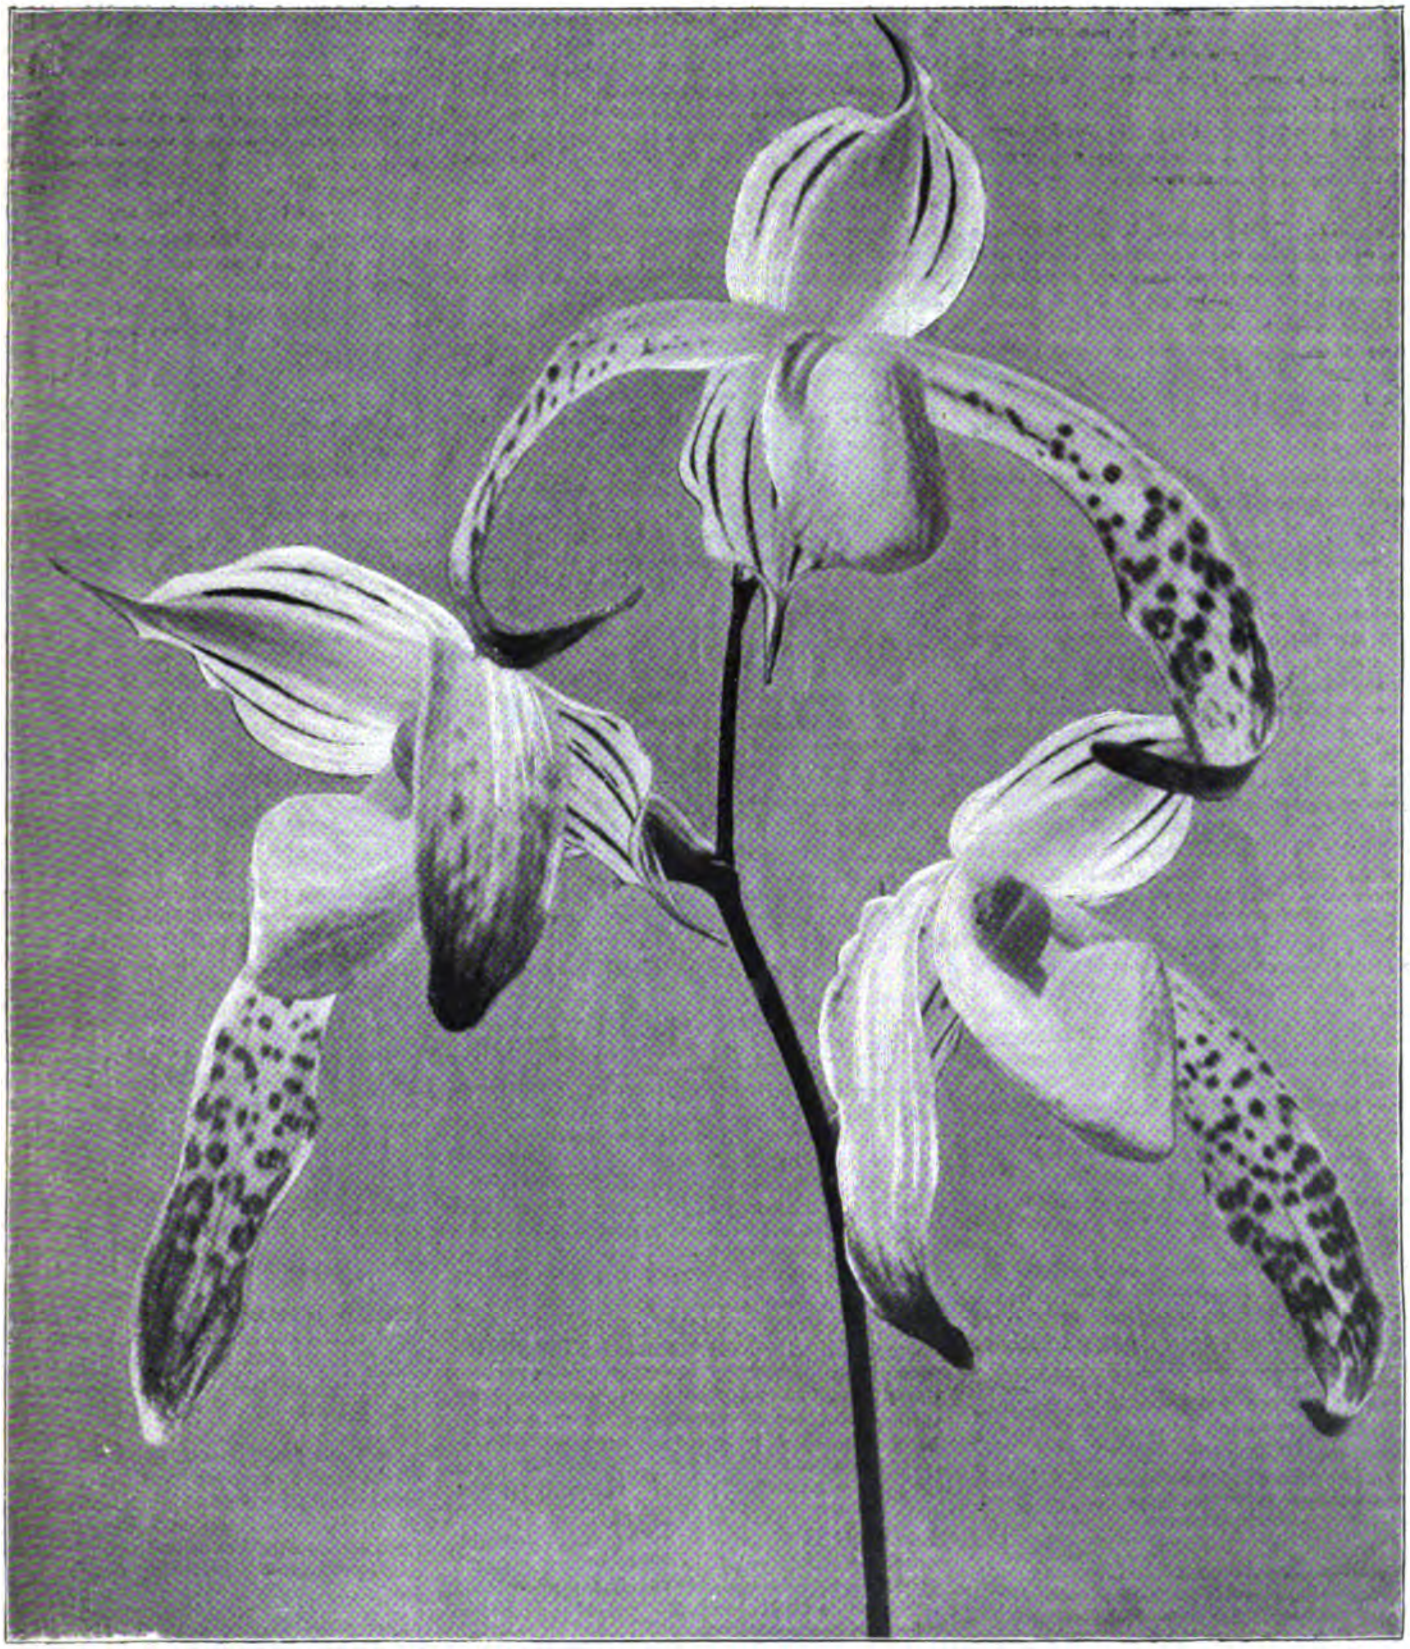

Fig. 104.—Cypripedium Stonei platytænium. (See p. 273.)

(From the Collection of Sir Trevor Lawrence, Bart.)

"Botanical Magazine."—The May number contains descriptions and coloured illustrations of the following :—

Nicotiana sylvestris, Spegaz.—A native of mountain valleys in the province of Salta, Argentina. It is a tall, coarse-looking, sticky, herbaceous plant, with the upper leaves sessile, pandurate, and with numerous tubular white flowers in dense terminal panicled cymes. Each flower is about 3 in. long. Kew ; t. 7652.

Cyrtanthus parviflorus, Baker, in *Gard. Chron.*, 1891, i., 104.—A small-flowered species with orange-scarlet flowers. It is a native of the Cape Colony ; t. 7653.

Alnus nitida, Endlicher.—A West Himalayan species with cordate ovate-lanceolate leaves, and long, drooping male catkins, bearing the flowers in rings, separated by interspaces ; female flowers in erect obtuse catkins. Kew ; t. 7654.

Dahlia Maximiliana, Hemsley, in *Gard. Chron.*, 1879, xii., 525.—A tall-growing species with mauve flowers, flowering after the Chrysanthemum, and therefore a valuable addition to winter-flowering conservatory plants ; t. 7655.

Veronica Dieffenbachi, Bentham, see *Gard. Chron.*, 1898, ii., p. 154, fig. 41 ; t. 7656.

The Chelsea Garden.—We are now enabled to give the names of the representatives of the various bodies who will form the Committee of Management. It would seem as if the committee were greatly too cumbrous to manage so small a garden, with so limited a revenue. It contains, moreover, many who are not gardeners or botanists. The provision for instruction in systematic botany—one of the greatest wants of the time—does not seem adequate. The representatives appointed by the trustees of the London Parochial Charities are the Hon. Mrs. Evelyn Cecil, the Right Hon. Sir M. E. Grant Duff, Mr. W. Hayes Fisher, M.P., Mr. R. B. Litchfield, Mr. L. B. Sebastian, Sir Owen Roberts, Mr. Sidney Webb, the Rev, R. H. Hadden, and Mr. Evan Spicer. The Treasury has appointed Mr. A. B. Freeman-Mitford, C.B. ; and the Lord President of the Council has appointed the Right Hon. Sir Herbert Maxwell, M.P. Dr. D. H. Scott, F.R.S., of Kew Gardens, is the representative of the Royal Society ; and Professor S. H. Vines, F.R.S., of Oxford Botanic Gardens, of the Senate of London University. Mr. J. R. Upton has been appointed by the Society of Apothecaries ; and Mr. Michael Carteighe by the Pharmaceutical Society. The appointment by the Technical Education Board of the London County Council has not yet been completed, but it is understood that a committee have recommended the appointment of the chairman of the board, Mr. T. A. Organ. Earl Cadogon, or any person to be delegated by him, is an *ex officio* member of the committee. Mr. H. Howard Batten is acting as hon. secretary to the garden, and any communications on the subject may for the present be addressed to him, at 3, Temple Gardens, Temple, E.C.

Pæony Disease.—Dr. Ritzema Bos mentions a fungus, Botrytis pæoniæ, as the cause of disease in the Pæony. All affected leaves should be burnt. As the fungus spawn is internal, external applications are of comparatively little use, unless as preventatives.

Belgian Colonial Horticulture. — A society has been formed in Belgium under the name of l'Horticole Coloniale. Ltd., to develop the colonial resources of Belgium. The capital is 2,400,000 francs (£96,000). The society is to absorb the "Horticulture Internationale" of Brussels, as well as the establishment of M. Lucien Linden at Moortebeeke. A vast colonial establishment is to be founded at Linthout, for raising economic plants in large quantities. The new society will be managed by M. Lucien Linden. Among the shareholders, we observe the names of Madame Linden, M. A. Madoux, the Bleichroder Bank at Berlin, M. Van Lansberge, formerly Governor-General of the Netherlands Indies ; Count Adrien d'Oultremont, and others.

The History of the Laurel-Cherry.—M. E. Roze contributes to the March issue of the *Journal de la Société Nationale d'Horticulture de France* some notes on the history of the Laurel-Cherry, commonly, but erroneously called Cherry-Laurel, or Prunus Lauro-cerasus. He remarks that, according to Charles de l'Escluse, the plant was to be found towards the end of the sixteenth century not only in Vienna but also at Nuremburg, in the garden of Joachim Camerarius, to whom he had sent it, but that this shrub has been previously planted in the garden of Prince Doria, at Genoa. It was cultivated in Switzerland from the beginning of the seventeenth century, as Jean Bauhin, who died in 1616, informs us that the Laurel-Cherry had fruited at Lucerne, and that he had himself sown some of the seed at Montbeliard, but without success. However the introduction of this ornamental shrub into France may have been effected, the Laurel-Cherry was found, in 1636, in the Jardin Royale des Plantes Médicinales, Paris (now the Museum of Natural History), as it is mentioned in the catalogue of the garden published that same year by Guy de la Brosse. It is met with again in 1689, according to the catalogue of the same garden, attributed to Sherard. And it is evident that it had time to become distributed over France during the whole of the seventeenth century. Then, Duhamel du Monceau, in his *Traité des Arbres et Arbustes qui se cultivent en France en Pleine Terre* (1755), does not fail to speak of the Laurel-Cherry. He tells us that there existed at that time, in addition to the primitive type with green leaves, sorts with foliage variegated with yellow and with green.

The Fertilisation of Plants. – M. Guignard presented to the Academy of Science on April 4, a paper on "The Processes of Fertilisation as observed in Lilium Martagon." The paper is very technical, and can only be followed in its entirety by specialists. In the pollen-tube, as is now well known, are formed two cells, one vegetative, one reproductive. In the embryo-sac also are various nuclei, one of which is called the polar nucleus, as well as groups of cells at either end. As soon as the pollen-tube penetrates the embryo-sac, one of the two male nuclei unites with the polar nucleus, the other with the oosphere or egg-cell. The male nuclei elongate into the form of a hook or crescent, ultimately becoming spirally twisted. Although no cilia are visible, M. Guignard does not hesitate to call this an "antherozoid" from the close analogy there is between this and the male reproductive bodies of the higher cryptogamous plants and of some gymnosperms (Ginkgo, Cycas). In summing up, M. Guignard says that the essential phenomenon observed, by M. Nawaschin and himself, consists in a two-fold sexual union in the embryo sac, the one resulting in the formation of the embryo, the other developing into the albumen or perisperm in which is stored up the food required by the embryo. If these results be confirmed, the gap between the vascular cryptogams and the flowering plants is again bridged over. The albumen, as well as the embryo, thus seems to be the result of a sexual process, which is quite a novel idea. The variations in the number of the chromosomes, suggests to us a possible explanation of the phenomena of "sporting" and of variation generally. It seems that the life-history of the flowering plants and all that it implies, must be studied in the development of the embryo-sac and its contents. These researches must therefore be made by the few, for not many can be endowed with the necessary skill or material requirements.

Large Trees at Pitfirrane, Fife.—The lands of Pitfirrane, in the west of the "kingdom" of Fife, have been held by the family of Halkett for the past 500 years. This may to some extent account for the number of fine old trees which adorn the spacious park around their ancestral home. The present owner, Sir Arthur, takes a lively interest in arboriculture, and is justly proud of the sylvan features of his park. Tall and handsome examples of broad-leaved trees are admirably grouped ; and the well-balanced, umbrageous heads of many single specimens in the open park are a striking feature in a beautiful landscape. The girth measurements of some of the finest stems of the trees have just been taken by Sir Arthur, from which we learn that of ten Oaks with grand boles, the largest girths 14 feet 6 ins., and the average girth is 14 feet. Of ten Beeches, the largest is 17 feet, and the average 15 feet 4 ins. ; of ten Scots Elms, the largest is 20 feet 7 ins., and the average 15 feet 4 ins. ; of ten Planes (Sycamores), the largest is 17 feet 6 ins., and the average 13 feet 6 ins. ; of seven Ashes, the largest is 15 feet 5 ins., and the average is 14 ft. A Lime girths 15 feet, and an enormous Willow as much as 19 feet. All the measurements were taken at 3 feet from the ground. The record is a good one, and probably among the best that can be found in the county of Fife, which is noted for its ancient family mansions and richly-wooded parks.

Destruction of Charlock. — Under the auspices of the Essex County Council, experiments are being conducted on the destruction of charlock in field crops by sulphate of copper. The following directions for spraying are given : Dissolve 5 lb. of ground sulphate of copper (blue stone or blue vitriol) in 25 gallons of water. By means of a spraying-machine, distribute this solution in the form of a fine spray over the crop. If applied while the charlock is still young, on a still day, and in fine weather, this quantity should be sufficient for 1 acre.

The Royal Gardeners' Orphan Fund.—At a meeting of the committee, held on the 29th ult., the sum of £32 2s., inclusive of two annual subscriptions for one guinea each, was received from the Gardeners' Charity Guild, per Mr. G. Dean, as the result of the smoking-concert held at the Cannon Street Hotel on March 15 ; and six members of the committee of the Guild were placed on the list of life-voters.

Rose Show Fixtures in 1899.—The following dates of Rose shows are in addition to those notified on p. 202, April 1. Mr. Edward Mawley, of Rosebank, Berkhamsted, Herts, who has kindly supplied us with these particulars, will be glad to receive notification of any Rose shows not included in either list, or of any horticultural exhibitions where Roses are made a leading feature. June 13 (Tuesday), Cambridge ; June 21 (Wednesday), Isle of Wight (Shanklin) ; June 28 (Wednesday), Maidstone, Reading, Richmond, and Ryde ; June 29 (Thursday), Sutton ; July 5 (Wednesday), Brockham and Tunbridge Wells ; July 6 (Thursday), Farningham ; July 7 (Friday), Hereford ; July 13 (Thursday), Bedale ; July 20 (Thursday), Sidcup ; July 22 (Saturday), Newton Mearns.

Apples from the Antipodes.—The officials of the Orient Company have received information stating that the *Austral* is on her way with some 23,000 cases of fruit, and the *Australia* with 8800 more—a total of 31,800 cases.

—— A curious discovery has been made at Chesham, Bucks, by Mr. Joseph Hearn. While unpacking a box of Tasmanian Apples he found one wrapped in paper, on which was written : "This Apple was packed by Miss Kate Piety, granddaughter of late Thomas Piety, of Kent, England. If any of you know their address, please send it to me at Derwent House Falls, New Tasmania. I am very dark and good-looking, and would be pleased to see any of you who come my way." Some one in Maidstone having heard the above story, and hearing that a niece of Mr. Thomas Piety was still living in Maidstone, sought her out.

This proved to be a Mrs. SARAH ANN BRISSENDEN, *née* SARAH ANN WRIGHT, of the Rose and Crown, Maidstone.

IS ELEVATION NECESSARY IN THE FORMATION OF ROCKERIES?—In the Botanic Gardens at Cambridge, Mr. LYNCH has placed pieces of stone upon the ground level, and between them are planted rock or alpine plants. Numerous species have been used in this novel method, and the result has led Mr. LYNCH to the conclusion that the slight elevation obtained in most rockeries is not of value in the cultivation of alpine plants, but it increases very considerably the difficulties in affording the necessary water to the plants during dry weather. But, of course, situations differ widely from each other, and in every garden the conditions of soil, &c., are not so dry as at Cambridge. It would seem that in low and damp situations, the elevation even afforded by an average rockery would help to ameliorate the unsuitableness of local conditions. Apart from the question of necessity there remains also that of effect, and a raised rockery, providing the structure is placed together with taste, and an appreciation for what is natural and congruous, is no doubt a more striking feature in a garden than the plants would furnish when placed upon the ground level. In a few cases also, the rockery is of equal interest with the plants, that of Sir CHAS. ISHAM'S, for instance, at Lamport Hall, figured in these pages on September 25, 1897. But Mr. LYNCH does not advise the sacrifice of elevation in all rockeries, and states merely that he is satisfied the slight degree thus obtained is of no practical value to the plants. It is a matter that many of our readers may try under their own circumstances.

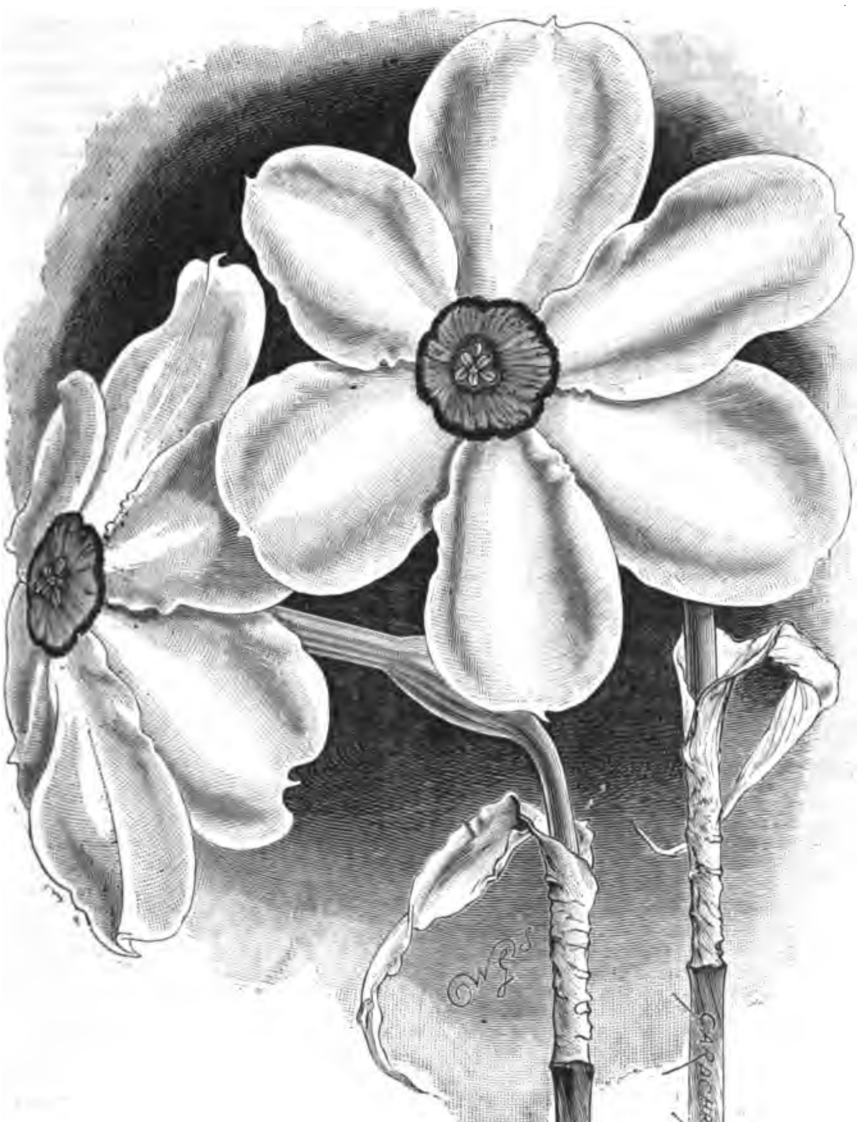

FIG. 105.—MR. HARTLAND'S NEW NARCISSUS. (SEE P. 284.)

"FLORA OF KENT."—The above work, comprising an account of the flowering plants, Ferns, &c., growing spontaneously in Kent, with notes on the topography, geology, and meteorology, and a history of the botanical investigation of the county, with two maps, by FREDERICK JANSON HANBURY, F.L.S., author of *An Illustrated Monograph of the British Hieracia*, and editor of *The London Catalogue of British Plants*, &c., and EDWARD SHEARBURN MARSHALL, M.A., F.L.S., Vicar of Milford, Surrey, is to be published almost immediately. It will be an octavo volume of between 500 and 600 pages. It was commenced over twenty years ago, when, for purposes of the *Flora*, the county was divided into ten districts. Each of these districts has been explored botanically, both by the authors and by the many friends and contributors who have helped to bring this work to its present standard of completeness. In addition to these more recent observations, it will include all that have been previously published, and copious records from the public and other herbaria which have been consulted. There are two maps. The larger, reduced from the ordnance survey, shows the divisions of the several botanical districts; the smaller is coloured geologically. In the introduction the topography of the county is described, separate sections being devoted to its botany, geology, and meteorology. The history of botanical investigation in the county is traced from the sixteenth century onwards. A table, showing the distribution of each plant as regards its occurrence in Essex, Middlesex, Surrey, and Sussex, with complete lists of contributors and of the books and herbaria quoted, are also given. The work will be issued to subscribers. Orders may be sent to FREDERICK J. HANBURY, Plough Court, Lombard Street, London, E.C.

INTERESTING TO "PAST" AND PROSPECTIVE KEWITES.—During the present month a regulation will come into effect obliging all young gardeners employed in the Royal Gardens, Kew, to be dressed in suits of blue serge. Previously, the only rule affecting dress has applied to visitors to the gardens, who for years have been forbidden entrance to the establishment unless "decently" clad. The gardener has worn fustian, broadcloth, or cord, as his tastes have guided him.

FERN HYBRIDS.—Mr. CHAS. T. DRUERY, 11, Shaa Road, Acton, is preparing a paper on "Hybrids and Crosses of British Ferns, and their Varieties," for the forthcoming Conference at the Royal Horticultural Society, and would be glad to receive fronds and evidence of crossed or hybridised Ferns, for use in connection therewith.

THE THIRTY THOUSAND DOLLAR CARNATION is now in England, in the extensive collection at Dover House, Roehampton. Mr. PIERPONT MORGAN, who has recently arrived in this country from the States, and whose admiration for all sections of the Carnation, but particularly that of the Souvenir de la Malmaison type, is well known, brought with him a quantity of blooms and a number of cuttings of this variety, which, it will be remembered, is known as Mrs. Thomas W. Lawson. The cuttings, after travelling so many miles, are not over promising, and Mr. McLEOD is not without doubt as to whether he will be successful in rooting them, but he may be trusted to establish them if it be possible. In such an event, it will not be very long before English-grown plants in flower of this much-talked-of Carnation may be anticipated at the Drill Hall. These cuttings, we believe, have been selling at £10 and £12 apiece.

IVY-STEALING IN THE EXETER DISTRICT.—In our last issue we published details concerning a conviction at The Castle of Exeter Court for Fern-stealing. From particulars kindly furnished by Mr. A. HOPE, it seems that at the Exeter Sessions Court, on May 29, a similar case was conducted. The prisoners in this instance, however, had torn down growing Ivy from trees on the estate of the Hon. MARK ROLLE, and had tied it in bundles for sale in the town. Both prisoners were sentenced to fourteen days' imprisonment with hard labour.

GARDEN PRODUCE BY RAIL.—A departure by the united South-Eastern and Chatham & Dover Railways, which will be much appreciated by town dwellers and farmers, is just being instituted in regard to the conveyance of farm produce direct from the producer to the consumer. Following the example set in this direction by the Great Eastern Railway—a development which has proved a success—the South-Eastern and Chatham Companies announce that henceforward farm and market-garden produce will be conveyed to consumers by passenger train from all stations to London, and from all stations (except those within twenty miles of Charing Cross) to the principal towns on the two systems at a reduced charge of 4*d*. for 20 lb., and 1*d*. additional per additional 5 lb. up to 60 lb., including delivery within the usual limits. In connection with this new service light and inexpensive boxes are on sale at all the Companies' stations.

FLORAL DECORATIONS AT CHESTER.—On the occasion of the visit of H.R.H. the Prince of WALES to Chester Races on May 2, the enclosed paddocks near the Grand Stand were finely decorated by Messrs. DICKSON, Ltd. The plants were effectively grouped in the centre and around the sides of the enclosed ground, and formed a very attractive feature in the paddocks. The pale golden Cupressus macrocarpa lutea, which originated in the Chester Nurseries, was used to good effect with the fine specimen Palms, Bays, Euonymus, Japanese Maples, Rhododendrons, Azaleas, and many other species of decorative-plants.

NEW NARCISSUS.

MR. HARTLAND of Cork sends us blooms of a cross-bred Narcissus of great beauty. It is a cross from N. poeticus var. ornatus and another, and is remarkable for its large size, the reflected condition of the white perianth segments, which are bent back nearly as in N. cyclamineus, much more so than is represented in the illustration (fig. 105, p. 283). The segments also overlap one another in a curious fashion; but whether this was peculiar to the specimen we saw, or is general, we do not know. We hope Mr. Hartland will not give it a Latin name.

TREES AND SHRUBS.

FORSYTHIAS.

THERE are few species of spring-flowering shrubs that deserve greater attention than the Forsythias. I have recently noticed in this neighbourhood some magnificent specimens of F. suspensa, the charming blossoms of which are so profuse as to almost hide from view the stems and branches. One wonders that such a lovely-flowering shrub is so seldom seen, for it is a quick grower, and thoroughly hardy. The blossoms also are seldom injured by frost. As a climbing plant against a wall, or a specimen tree in the border, it is very effective, and the plant may be forced in much the same way as an Azalea or Rhododendron. The deep-yellow flowers are borne on slender pendulous branches. The trifoliolate, deep-green leaves are deciduous, and the new ones appear after the tree has flowered. F. suspensa succeeds in any good garden soil, but preferably a soil containing much sandy loam should be chosen. Propagation may be effected by means of layers in summer, cuttings of ripened growths in autumn, or by grafting on stocks of the common Privet.

F. Fortunei is regarded by some authorities as a distinct species, but for garden purposes, it and F. suspensa may be classed as synonymous. In F. intermedia we have an interesting hybrid between F. suspensa and F. viridissima. From small plants I have seen, it would appear that the flowers resemble in shape and colour those of F. suspensa, but in growth it is so rapid as to be similar to that of F. viridissima. It is well worth planting. A description of this plant may be found in *Garten Flora*, 1891, p. 82.

F. viridissima is a species that differs from all others in being a much more rapid grower, and forms a small bush 10 or 12 feet in height. Its flowers are smaller in size, but are produced in even greater profusion. They are deep yellow in colour, tubular in shape, and generally appear during March or April. The leaves are deep green, linear lanceolate, simple and entire. It is an admirable plant as a climber against a wall, and it is equally useful in the shrubbery border. Introduced from northern China in 1845; it was described in the *Botanical Magazine*, p. 4587. *E. S., Woking.*

HOME CORRESPONDENCE.

TO FORCE CLEMATIS MONTANA.—Upon a recent visit to the nursery of Mr. H. Henkel, at Darmstadt, Germany, I saw many plants of the above species in flower. It is a very valuable plant for forcing. With respect to the treatment, there is, said Mr. Henkel, no difficulty, but it is very necessary to select good established plants. The plants then in flower had been cultivated in pots for two years. Beyond this, C. montana may be treated very similar to Prunus, Deutzia, &c. Mr. Henkel's plants are about 1 to 1·5 metres high, quite covered with the umbels of their white, slightly-scented flowers; the climbing branches are tied up to stakes, forming elegant pyramids. *C. K. S.*

SKIN IRRITATION FROM COLEUS LEAVES.—Two instances have come under my observation where persons from handling these plants have become affected by a skin rash and swollen eyelashes. Primula obconica has no effect whatever upon myself, while the Coleus produces intense inflammation. The milk-like sap of the Fig on some people's skin will produce large blisters and intense irritation, the effect of which is felt for weeks afterwards; but others are proof against either the Fig, Primula, or Coleus. *Harry W. Whiting, Stoughton Grange Gardens, Leicester.*

CAMELLIAS.—Having once had charge of 4000 Camellia plants in 200 varieties, my opportunities of learning the peculiarities of varieties and the usual methods of culture were of no common kind. It is a fact that the Camellia is not nearly so popular a plant as was once the case; and as your correspondent, "E. H. S.," remarks, the Chrysanthemum has done much to supplant them, and rightly, as I think, when we consider the amount of house-room required to have a good display of both. Then, again, the flowers of the Camellia are ill adapted to travel, the petals bruising so easily [if badly packed. ED.]. The blossoms are, moreover, less well adapted for arranging in vases in a cut state. Then, again, when the plants are small, flowers with long stalks cannot be cut with impunity. I am well aware that a Camellia bloom is usually taken without any part of the shoot on which it grew, and is then "wired," and thus used for many purposes, but can this be said to be the best way of showing the Camellia? The blooms themselves, owing to their regular and stiff outline, are nowadays voted too prim. However, it is not for the purpose of decrying the Camellia that I pen this note, but purely to point out some drawbacks attending the use of the flowers when cut from a plant. The finest specimens are obtained by planting in a cold greenhouse or conservatory, in a compost consisting of fibry sandy-loam and peat, two parts of the former to one of the latter, and affording the borders good drainage, for the Camellia requires much moisture at the roots when making new growth, and again when swelling their buds, but it dislikes stagnant moisture. Camellias may be planted against the back walls of lean-to Peach-houses and vineries, succeeding in early forced houses where the whole of the roof-glass is covered with the trees. In such a position the Camellia luxuriates, the moisture required for the Peaches in February, March, and April, just suiting its requirements at that season; and again, when the fruit is ripening and the trees are resting, the prevailing conditions of a forcing-house are suitable. Late vineries and peacheries are not so well adapted for the plants, the amount of direct sunlight browning the leaves before they can obtain shade from the Vines and Peaches. True, shading can be afforded the trees, but this gives trouble. Species and varieties of Camellia which make long shoots may here be utilised, as such shoots are readily tied to the wires upon the wall, and the blossoms are better adapted for decoration when cut with a good length of shoot, such are C. Mathotiana, C. m. alba, C. Donckelaari, C. Chandleri elegans, C. Marchioness of Exeter, and C. Prince des Fleurs. Potting is best performed directly the plants have finished flowering, except perhaps those that have been severely pruned. This, as a rule, is seldom necessary, as, with due care, the cutting of the blooms is sufficient pruning. Extra large pots for small plants are not necessary nor desirable; and the soil recommended for a border is quite suitable, with the addition of some silver-sand. [The Camellia being in its native home an inhabitant of forests, growing in deep shade, has requirements that are well met by mixing with the loam one-sixth to a quarter of decayed wood-soil, that is, faggot-wood or the like, which has laid in a heap in a moist shady place till decayed, the decayed portions being sifted out of it yearly, and laid on one side for use till all be decayed. This is precisely the sort of plant-food it obtains in a state of nature, and may take the place of peat or of leaf-soil in Camellia compost. ED.] Pruning should be done where required just previous to new growth being made. In the case of small or half specimen plants, pruning only should not be depended upon to obtain the necessary shape; by bending the shoots downwards, additional growths are forced from the nodes below. When the plants are making their growth, they should be syringed twice daily, to encourage growth, and wash off the black aphis. Top-dressing with loam and dried cow-dung is best done previously to new growth being made. *E. Molyneux.*

—— Mr. Chapman's excellent reply to "B. C.'s" enquiry at p. 262 of your last issue, reminded me of some failures that have followed the use of such a compost as Mr. Chapman recommends. Your correspondent grows these plants exceedingly well, but there is a vast difference in loams, both in their chemical and mechanical compositions. Some calcareous loams ought never to be mixed with peat-earths for hard-wooded plants, particularly for such as are not repotted frequently. The best soil for Camellias is one taken from pasture-lands resting on the red sandstone, or from granite formation, and is neither light nor heavy in texture. If the pasturage is of fine quality, skim it off about 1½ inch in thickness, break it up small, or according to the size of the plants to be potted, and add nothing whatever to this, but repot firmly. With careful after-treatment, it is astonishing how quickly Camellias will thrive in this. If the herbage is of a coarse nature, it would be advisable to char the grass over a wood-fire before using. I could explain how I brought an extensive collection of large and small plants from a dying condition into robust health and vigour; but perhaps as Camellias are neglected in the immediate present, the time is not yet opportune. *J. Easter, Nostell Priory Gardens.*

WINTER SALADS.—I entirely agree with your correspondent on p. 270. We have for years grown here, in north-west Yorks, the large form of Corn Salad, "*Mâche a grandes feuilles*," as the French catalogues call it, and have been able to cut from it in the severe winters of the past—and, indeed, salad from under the snow when Lettuces were gone. If plunged at once in cold water (not taken to a hot kitchen to thaw), it makes, with the addition of a few seedling Onions, a salad (in mid-winter) which no epicure would despise. You see I am a lover of what one of your correspondents calls, rather contemptuously, "green-meat." I am far from being a vegetarian, but I cannot help thinking that, if more "green-meat" and less "red-meat" were used in England, our health might be better. *R. Milne-Redhead, Clitheroe.*

—— I am sending two Lettuces of Stanstead Park (Cabbage). I have been cutting such Lettuces ever since the first week in March, and have not been without plenty during the whole winter. A batch of All-the-Year-Round gave me a fine supply up to the end of January. The seed was sown in August, 1898; and that of Stanstead Park in the first week in September, 1898. All-the-Year-Round affords good winter supplies, but is not so good as Stanstead Park in early spring. *W. J. Rus[illegible], jun., Woodlane Nurseries, Falmouth.* [Very good specimens, weighing about ¾ lb. when partially trimmed. ED.]

HEPATICA ANGULOSA VARIETIES.—Mr. Lorenzen, Copenhagen, Denmark, has written to me regarding my remarks upon the varieties of H. angulosa in the *Gardeners' Chronicle* of April 15. Mr. Lorenzen informs me that he has a fine light rose-coloured variety of H. angulosa, which he got from a German nursery three years ago, and a fine white-flowered variety obtained from Holland in the autumn of 1897. A flower of the latter, nearly over when pulled, was enclosed for inspection, the other being out of bloom. I feel greatly obliged to Mr. Lorenzen for his most interesting letter. It is prized as a fresh proof of the international good feeling so prevalent among those of kindred tastes in flowers and plants. *S. Arnott.*

EUCHARIS × STEVENSII.—This garden hybrid, between E. candida and E. Sanderi, is one of the most free-flowering of Eucharis. Given a moderate stock of plants, so that fresh batches can be periodically brought forward into a little extra heat, one need seldom be without their flowers. The lasting qualities of the flowers, either in a cut state or upon the plants, are unusually good. *P. Bott, Wentworth Gardens.*

BIRDS AND FRUIT-TREES.—The latter part of my communication in last week's issue is a little misleading. In the spring of the year insects are very plentiful, with the swelling and opening of vegetative buds, and insect-eating birds find plenty of food. It is in a dry autumn, when insect-life is comparatively dormant, having commenced the hybernating stage, that such food is scarce, and Peas and Pears suffer by tom-tits in consequence. It is then that a few pounds of suet as an artificial food does good service. *R. M., Newbury.*

MAY-DAY, 1899, NORTH O' TWEED.—Even so far north as Edinburgh, May-day occasionally gives us a foretaste of summer. But this year on May-day the east wind swept over sea and land with relentless hardness, carrying sleet and snow, or rain colder than either in all directions. Fortunately, the season is a fortnight or three weeks behind time, and with the exception of a few Peaches and Apricots, and precocious Pears on walls, the fruit-buds are still, in the main, safe. The last day of April gave little warning as to the close proximity and recurrence of wintry weather. That May-day was foggy and wet in Edinburgh almost goes without saying. In Glasgow the sunshine on Sunday was succeeded by a downpour of cold rain that lasted late in the afternoon. Galashiels had a heavy fall of snow, which lasted for several hours, and which needed the heavy rain of all the rest of the day to clear it away. At Greenlaw snow fell from early morning till late in the afternoon. At Dumbarton a heavy fall of snow fell in the morning, followed by a wet day. Hawick also had 4° of frost, a snow-storm, and a thunder-storm later on. Langholm had thunder, and a heavy down-pour of rain. Moffat a slight fall of snow, thunder and rain. The Blairgowrie folk, in whom the writer is specially interested, having lectured there on fruit-culture last year, instead of finding their well-cropped fruit and other gardens sparkling with May dew, found them covered with snow. It snowed with little or no intermission from 5 A.M. till 11 A.M., at times falling very heavily, and reached a depth of from 3 to 4 inches in parts of the surrounding country. Still more wintry reports reach us from central Perthshire, where the abnormally backward spring of 1899 seems to have culminated in their winter on the morning of May-day. The snow began to fall thickly and fast about four in the morning, and continued till noon, converting the upland roads and paths into masses of snow and slush several inches deep. The extremes of symptoms, as well of seasons, however, seems to meet a good deal further south at Melrose, where the notes of the cuckoo were said to be distinctly heard in the Calker's Glen on the Abbotsford Estate, while the whole surface was covered with snow. *D. T. Fish.*

SOCIETIES.

ROYAL HORTICULTURAL.

May 2.—The usual fortnightly meeting of the Committees of this Society was held on Tuesday last in the Drill Hall, James Street, Westminster. The exhibits were considerably less crowded than on the last occasion, but there was a good display nevertheless, and from the unusual quantity of Narcissi shown, including some very beautiful novelties, there was a degree of brightness that is seldom surpassed. In addition to the large trade exhibits, which were really representative collections of the choicest varieties of Narcissi, the Committee who adjudged this section of the Show recommended three Awards to novelties that are described below.

The exhibits with which the Floral Committee were chiefly concerned, included a splendid display of Irish-grown Tulips from Messrs. Hogg & Robertson, Dublin, who may be congratulated on their appearance in the Drill Hall; Tulips also from Messrs. Barr & Sons, &c. Roses from Messrs. Paul & Son, Cheshunt, and Mr. Mount; groups of Ferns from Mr. H. B. May, and Messrs. J. Hill & Sons, Edmonton, and several exhibits of hardy flowering plants. This Committee recommended Awards of Merit only in two instances to Richardia Pentlandi, Tring Park var., and R. suffusa, both being shown from the gardens of Lord Rothschild.

There was a nice display of Orchids, and the Orchid Committee recommended Awards of Merit in seven instances, or an equal number to the whole of the other committees combined.

The Fruit Committee made no award to any novelty, and the chief exhibit before this body was a comprehensive collection of vegetables and salads from the Duke of Northumberland's garden at Syon House.

In the afternoon a paper, entitled "The British and Swiss Alpine Floras," was read by Mr. E. A. N. Arber, B.A., an "old" student at Chiswick.

Floral Committee.

Present: W. Marshall, Esq. (Chairman), and Messrs. John Fraser, Owen Thomas, Chas. T. Druery, H. B. May, R. Dean, W. Howe, J. Jennings, J. F. McLeod, R. B. Lowe, C. J. Salter, Chas. E. Shea, H. S. Leonard, J. W. Barr, Chas. Jeffries, Geo. Gordon, J. D. Pawle, E. H. Jenkins, Herbert J. Cutbush, E. Beckett, E. T. Cook, H. J. Jones, Geo. Paul, and Ed. Mawley.

Heliotrope Madame Fillay, shown by Mr. J. Hudson, gr. to Leopold de Rothschild, Esq., Gunnersbury House, Acton, is a new Continental-raised variety, with dwarf, compact habit; it produces large trusses of pale-coloured flowers immediately above the foliage.

Mr. Geo. Mount of Canterbury again staged beautiful Roses, there being twelve dozen blooms, in addition to a number cut as long sprays with foliage. Caroline Testout, Ulrich Brunner, Captain Hayward, were shown in quantity, but numerous other varieties were represented by glorious blooms, though fewer in number (Silver Banksian Medal).

Messrs. Paul & Son, Cheshunt, made a very gay exhibit of Roses in pots, almost every plant being crowded with a fine show of flowers. Some of the more prominent varieties were Etoile de Lyon, Caroline Testout, Viscountess Folkestone, Marquise Litta, and a fine new white H. T., named Victoria Melita. The Dawson Rose, a single-flowered variety, is a charming plant for the wilderness garden (Silver-gilt Banksian Medal).

Mr. G. W. Piper, Uckfield, Sussex, again exhibited a number of blooms of the pretty and peculiarly-tinted Tea Rose, called Sunrise.

The exhibit of Ferns from Mr. H. B. May, Dyson's Road Nurseries, Upper Edmonton, was composed on this occasion of species and varieties of Gleichenia, there being thirteen forms shown of this very beautiful genus. We noticed G. longipinnata, G. dichotoma, the well-known G. speluncæ, one of the very best; G. Mendeli, a useful Fern for forming specimens; a strong-growing form of G. rupestris, known as gigantea; and G. Backhouseiana, a comparative novelty, of dwarf habit and neat appearance (Silver-gilt Banksian Medal).

Messrs. J. Hill & Son, Lower Edmonton, made an interesting exhibit of Ferns, for the greater part consisting of varieties of Asplenium, and including such diverse forms as A. Nidus, A. caudatum, of Nephrolepis-like growth; and A. viviparum, a very finely-cut variety (Bronze Banksian Medal).

Richardia Pentlandi was shown by Mr. E. Hill, gr. to Lord Rothschild, Tring Park, Tring. He had six very strongly-flowered plants.

Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea, exhibited plants of a new variety of Codiæum named Mrs. Iceton. The variety has moderately broad leaves, coloured variously with red, yellow, and green. Messrs. Veitch also showed varieties of Rhododendron balsaminæflora, double flowered, in yellow, white, rose-coloured, &c. All of these different coloured double-flowered varieties were produced by seeds from one capsule, which resulted from a flower that had a petaloid stamen, fertilised with pollen from the perfect stamens. The flowers are very attractive, and the plants grow vigorously in a warm greenhouse.

Messrs. W. Cutbush & Son, Highgate Nurseries, London, N., staged a group of miscellaneous plants of a decorative character, including some of the more popular Ericas, new varieties of Azalea indica, Boronias, &c.

Auriculas, that at the last meeting were not more than average in quality, were represented by a moderate-sized group of beautiful varieties and novelties from Mr. Jas. Douglas, Edenside Nurseries, Great Bookham. But no award was made to any of these, nor to others shown by Messrs. Thos. Ware, Ltd., Hale Farm Nurseries, Tottenham. From these Tottenham Nurseries came also a few Tulips and other hardy flowers.

Messrs. Barr & Sons, King Street, Covent Garden, London, in addition to an extensive exhibit of Narcissi, showed a very nice collection of varieties of florists' Tulips, and an interesting little group of alpine plants in flower. Amongst some Erythroniums from Messrs. Barr, was a highly decorative variety called Pink Beauty.

The lovely yellow-flowered Fritillaria imperialis was exhibited by J. T. Gilbert Dyke, Esq., Bourne, Lincolnshire, who contributed a grand bunch of them.

Messrs. Wallace & Co., Kilnfield Gardens, Colchester, showed in company with other plants, a greenish-flowered Fritillary (F. Elwesii), Muscaria conicum, and the gay coloured Tulipa Greigi.

Seedling Primroses and Polyanthuses were staged by several exhibitors, including some from F. W. Campion, Esq., Colley Manor, Reigate (gr., Mr. J. Fitt), and Messrs. H. Cannell & Sons, Swanley. Messrs. Cannell's crimson-flowered Primrose, Miss Massey, was a very fine one.

Tulips were exhibited largely and grandly by Messrs. Hogg & Robertson, Mary Street, Dublin. There were about 150 huge bunches of these Irish-grown Tulips, and they were remarkable for excellent colour and good substance and size. The species of Tulipa were capitally represented, and attracted some interest. We noticed among these such as T. primulinum, the dainty little T. Clusiana, the spreading T. cornuta chinensis; the brightly coloured T. Kolpakowskiana, T. viridiflora, T. elegans, all well known, but representative of interesting types. The florists' Tulips were also present in large numbers, and a small but fine collection of Darwin Tulips completed this welcome exhibit from the Emerald Isle (Silver-gilt Flora Medal).

Messrs. G. Jackman & Son, Woking, exhibited a group of hardy and alpine plants, in which Gentiana acaulis and varieties of Primula Sieboldi were noticeable. They contributed also a fine lot of bloom of Magnolia conspicua, and M. alba grandiflora (Silver Banksian Medal).

AWARDS.

Richardia Pentlandi Tring Park variety.—A very large spathed variety as shown, and more rich in colour than this yellow Calla has been previously seen (Award of Merit).

Richardia suffusa.—A pale primrose-spathed Calla was shown under this name, reminding one of that known as R. aurita, but paler even than this one. The spathes are moderate in size, and at the interior base is a large purple stain. (Award of Merit).

Both of the above varieties were shown by Mr. E. Hill, gr. to Lord Rothschild, Tring Park.

Narcissus Committee.

Present: Messrs. J. T. Bennett-Poë (in the chair), C. R. Scrase-Dickins (Hon. Secretary), P. R. Barr, A. Kingsmill, J. Pope, R. Sydenham, W. Goldring, G. Titheradge, J. Walker, Revs. G. H. Engleheart and E. Bourne.

Narcissi, though not in their zenith as on April 18, were strongly represented in the hall, especially by the east-coast growers. The large bank of flowers in great variety staged by Messrs. Bath, of Wisbech, was an exceptionally fine exhibit, the blooms large, fresh, and well finished; Weardale Perfection was particularly striking (Silver-gilt Flora Medal).

A Silver Flora Medal was awarded to Messrs. Barr's large and comprehensive collection; and a Silver Banksian Medal to Messrs. T. S. Ware's exhibit.

Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea, had also a collection of Narcissi in variety.

A stand of new hybrid seedlings from the Rev. G. H. Engleheart seemed a centre of attraction. This was smaller than that of April 18, but every flower was well in advance of the varieties in cultivation, especially in refinement and distinction of form, and rich or delicate colouring. A few blooms of the splendid Will Scarlett, though staged as old flowers, still retained the wonderfully deep and glowing orange-scarlet in their large cups. Two beautiful flowers obtained Awards of Merit. There were also several large bunches of fine crimson-eyed Poeticus seedlings in this exhibit, and many other notable flowers.

Mr. R. O. Backhouse, Sutton Court, Hereford, was thanked for an interesting exhibit of seedlings; and Mr. J. Walker, Thame, submitted two flowers of a remarkably fine double yellow Incomparabilis.

AWARDS.

Narcissus × Marina, having a pale creamy perianth of perfect, rounded form, and large open saucer-like crown of softest lemon. From Rev. G. Engleheart (Award of Merit).

N. × Hesperus.—A variety with spreading segments of pale creamy-buff, the eye rich apricot-orange. From Rev. G. Engleheart (Award of Merit).

N. × Dorothy Kingsmill, from Andrew Kingsmill, Esq., Harrow Weald. This flower, raised by Rev. G. H. Engleheart, is a hybrid of extraordinary size, from a cross between Ajax grandis and triandrus. The flower is as large as that of grandis, is creamy-white, with something of the drooping character of triandrus (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, J. Gurney Fowler, Sydney Courtauld, H. J. Chapman, J. Gabriel, W. H. Young, W. H. White, W. H. Protheroe, A. Outram, T. Statter, H. T. Pitt, E. Hill, J. Jaques, W. Thompson, T. W. Bond, Walter Cobb, F. Mason, A. H. Smee, H. Little, J. Colman, and H. Ballantine.

Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), staged a group of interesting Orchids, specially remarkable in which were a fine specimen of the rare Cirrhopetalum Cumingi, with twenty-nine of its fan-like heads of bright rose-purple flower; a very fine example of Cirrhopetalum Colletti, with fine flower-spikes; Dendrobium crepidatum maximum, with which was shown the ordinary form much smaller in size and less bright in colour; D. × Nestor (Parishi × anosmum); D. × micans giganteum, one of the most beautiful of hybrids; D. × Stratius (Linawianum × Dalhouseianum), with singularly-formed pink flowers; the pretty little Masdevallia O'Brieniana, and a fine specimen of Pleurothallis ornata (Silver Banksian Medal).

W. Thompson, Esq., Walton Grange, Stone, Staffordshire (gr., Mr. W. Stevens), showed a group of excellent Odontoglossums cultivated and flowered in his usual superb manner. Among them were Odontoglossum × Ruckerianum ocellatum, a fine form with light rose-coloured flowers handsomely spotted with red-brown; O. luteo-purpureum, Thompson's variety, a very large flower, having all but the yellow tips of the sepals of a rich brown colour, the petals cream-white blotched with brown, and a handsomely-marked white labellum (Cultural Commendation); the fine O. l.-p. sceptrum Stevensii, a grand O. polyxanthum, with two flower-spikes (Cultural Commendation); a pretty light-coloured O. × excellens, with a fine-branched inflorescence; two superb forms of O. crispum, and the handsome Lælio-Cattleya × Hippolyta aurantiaca, with wholly orange-coloured flowers (Silver Flora Medal).

De B. Crawshay, Esq., Rosefield, Sevenoaks, showed a very remarkable group of Odontoglossums, in which were eleven distinct forms of O. × Andersonianum, ranging from the large nearly unspotted forms, to others densely spotted with various tints of brown (see list of Awards); the fine O. × Ruckerianum, Rosefield variety; O. triumphans "Rosefield Emperor," a grand form, near to O. t. Lionel Crawshay; the rare O. Nevadense, and a pretty blush-white Cattleya Mendeli (Silver Flora Medal).

Messrs. Jas. Veitch & Son, Royal Exotic Nursery, King's Road, Chelsea, showed Dendrobium × crepidato-nobile, a pretty and interesting cross between D. crepidatum and D. nobile, the white flowers tipped with rose, and bearing on the lip a singular claret-coloured marking, more nearly approaching in form to D. crepidatum, but the flowers were larger.

Messrs. Hugh Low & Co. were awarded a Silver Banksian Medal for a group of Cattleya Mendeli, one of the most distinct being C. M. Princess, blush-white, with purple marbling in front of the yellow-tinted tube. With them were good examples of Miltonia Roezli alba, Phalænopsis Sanderiana, Lælio-Cattleya × Latona, &c.

W. A. Gillett, Esq., Fairoak Lodge, Bishopstoke, sent cut spikes of a number of fine varieties of Odontoglossums, Cattleyas, and Dendrobiums, all excellently grown. Among them were fine forms of Odontoglossum crispum, one purple-tinted form scarcely expanded being especially good; excellent O. Pescatorei, O. × Coradinei, O. luteo-purpureum, O. Haynaldianum, a noble Cypripedium Rothschildianum, and some very large flowered Dendrobium nobile.

R. G. Fletcher, Esq., Withdean, Brighton, sent Selenipedium caudatum, and its pouchless variety Lindeni.

R. I. Measures, Esq., Camberwell (gr., Mr. H. J. Chapman), showed Cypripedium × Thyades (superbiens × Chamberlainianum), a curious cross, having the upper sepal pale-green with thin purple lines; the extended petals greenish white with numerous dark-purple spots, and crimped ciliate margin: the lip reddish-rose.

F. A. Rehder, Esq., The Avenue, Gipsy Hill, sent Cypripedium × Mrs. Rehder (Argus × Rothschildianum), a flower of fine substance of a reddish-yellow ground colour, the petals bearing many dark chocolate spots, the upper sepal tinged with green, and bearing a few dark lines. Also Miltonia flavescens.

C. L. N. Ingram, Esq., Godalming (gr., Mr. T. W. Bond), showed Lælio-Cattleya × Sir Wm. Ingram, a richly coloured hybrid between Lælia purpurata and Cattleya aurea.

F. M. Burton, Esq., Highfield, Gainsborough, showed a very fine Odontoglossum polyanthum and Cypripedium × porphyrites, probably a C. concolor cross, the greater part of the flower's surface being bright crimson-purple, with a few blackish spots on the petals.

AWARDS.

Epidendrum × elegantulum luteum (Wallisii ♀, Endresio Wallisii).—A fine colour variation; flowers borne in racemes of four or five on the upper part of the growths. Sepals and petals bright yellow; lip white, with slight rose shade in the centre. From Messrs. Jas. Veitch & Sons (Award of Merit).

Odontoglossum triumphans, Dulcote Variety.—Flowers large, each segment broad, and well proportioned; the light yellowish ground colour bearing large chestnut-brown blotches covering the greater part of their surface. From Walter Cobb, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes) (Award of Merit).

Odontoglossum × excellens McBeanianum.—A grand variety with very large flowers. Sepals broad, lemon-yellow with three large transverse red-brown blotches; petals white at the base, the outer half pale yellow, bearing one or two large brown blotches and some smaller. Lip oval, crimped, pale primrose-yellow with darker yellow crest, and three reddish blotches in the middle. One of the finest which has yet appeared. From Messrs. Jas. McBean & Sons, Cooksbridge (Award of Merit).

Odontoglossum × Ruckerianum Rosefieldiense.—Flowers large and well formed, purplish-rose with showy red-brown markings. From De B. Crawshay, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke) (Award of Merit).

Odontoglossum × Andersonianum Mrs. De B. Crawshay.—Flower nearly as large as in some forms of O. crispum, creamy-white with a very few reddish spots, and yellow callus on the lip. From De B. Crawshay, Esq. (Award of Merit).

Odontoglossum × Andersonianum "Raymond Crawshay."—A showy variety with large cream-coloured flower, the Indian red closely-placed markings being confined to the middle of the segments, leaving a broad unspotted margin. From De B. Crawshay, Esq. (Award of Merit).

Fruit Committee.

Present: Philip Crowley, Esq., in the Chair; and Messrs. Geo. Bunyard, E. Shaw Blaker, W. Poupart, A. F. Barron, T. J. Saltmarsh, A. H. Pearson, J. Wright, Alex. Dean, S. Mortimer, W. Bates, P. C. M. Veitch, G. T. Miles, Geo. Wythes, H. Balderson, F. Q. Lane, Jas. Smith, and M. G. Gleeson.

A box of excellent fruits of the Strawberry Royal Sovereign, from T. W. Campion, Esq., Colley Manor, Reigate, won from the committee a Cultural Commendation; and a like acknowledgment was made in the case of two dozen first-class fruits of Alexandra Peaches, shown by Mr. J. Ryder, gr. to the Countess of Limerick, Hawkeswick, St. Albans.

Mr. J. Mortimer, Rowledge Nursery, Farnham, again showed fruits of the Tomato Winter Beauty; and Mr. Owen Thomas, gr. to Her Majesty The Queen, Royal Gardens, Windsor, exhibited fruits and bine with fruits of Tomato Epicure. This is an exceedingly small-fruited variety, and the fruits are almost round, of good flavour, and exceedingly free; but they are scarcely so fleshy as they might be, and the skin is rather thick. Mr. Thomas also showed a number of pots of Peas, the variety being Harbinger, freely podded, and ready for the table.

A collection of vegetables and salads, from Mr. Geo. Wythes, gr. to the Duke of Northumberland, Syon House, Brentford, illustrated what is possible in the way of variety in vegetables in the early spring season. There were forty varieties of vegetables, and twenty of salads. A Silver-gilt Knightian Medal was awarded the exhibit. The Potatos shown included Sharpe's Victor, Veitch's Ashleaf, and a nice looking variety named Syon Early Perfection, obtained from a cross between Myatt's Ashleaf and Sharpe's Victor. Of Broccolis we noticed Veitch's Model, Late Queen, and Sutton's Continuity, all of them being capital sorts for home consumption. There were young roots of white and purple Milan Turnips, also Sutton's Forcing, sown only ten weeks since; White Spanish Onions, Early Nantes Carrots, Lettuce Hammersmith Hardy Green; Mushrooms, Prickly Spinach, Batavian Endive, French Beans Early Favourite and Syon House; Borecole; Sprouting Broccoli; excellent Asparagus from protected beds; Seakale; Cucumbers Improved Telegraph and Veitch's Perfection; Chives, Radishes, &c. A curious feature of the exhibit was a number of pots of Spinach—not a common method of forcing this vegetable. Mr. Wythes also showed excellent Rhubarb, from seed sown in April, 1897.

THE GREAT HORTICULTURAL EXHIBITION AT GHENT.

April 30 to May 9.—The important horticultural exhibition instituted by the Ligue Horticole "l'Union" for the province of East Flanders, and standing under the patronage of H.R.H. Prince Albert of Belgium, the Minister of Agriculture and Public Works, and the Governor of the Province, was opened to the public on Sunday, April 30, by H.R.H. Prince Albert. The opening was attended with but little ceremony.

The horticultural exhibits of kinds likely to be injured were mostly brought together under a canvas roof, covering an area of 60,000 square feet; Orchids, Anthuriums, Vriesias, Cacti, &c. and a few of the more valuable exhibits, in glass-houses existing in the garden; hardy trees of all kinds, and garden appliances out-of-doors. The site of the show, a garden attached to a dwelling about to be converted into a nunnery, occupies an area of 9 acres, so that plenty of space for the purposes of an exhibition of this kind was available; moreover, the garden being pretty well furnished with walks, fruit-trees, and ornamental trees and shrubs, and several glasshouses, gave advantages not to be ignored in such enterprises as this one. The general impressions on a first view were, that it was strong in Palms of moderate size, but weak in those usually seen at Ghent, which come from the gardens of amateurs, as might be supposed at a first show got together by the nurserymen of the town of Ghent and the province. Groups of Azalea indica, none of them consisting of large plants, gave colour, as did lesser groups of Clivias, Cytisus, Acacias, Azalea mollis, Choisya ternata, some Hippeastrums from Mr. Ker, Aigburth, and Callistemons.

On entering the show area by the only available door, the eye was taken by a stretch of turf flanked at the sides with Azaleas, but free of everything in the middle, ending in a mass of rockwork representing a wall of rock pierced by a low browed arch or opening, through which was observed a sunlit opening in a tropical landscape appropriately planted. The effect of the whole from the entrance-door, was exceedingly good. The walk skirting the sides of the building was carried over the aforesaid arch, affording the beholder a view the entire area from the height of about 10 feet from the floor. Of striking objects may be mentioned, Dracæna Goldieana, Acalypha Sanderi, many lots of Cocos Weddelliana, fine Boronias in groups and single plants, and Citrus sinensis, loaded with fruit.

ORCHIDS.

Taking Orchids first, we find Mr. Chas. Vuylsteke, of Loochristy, exhibiting a very fine lot of Odontoglossum crispum raised in Europe by artificial fertilisation. All were striking, but a brief description of each must suffice. Odontoglossum Magnificent, flowering for the first time, possesses a white lip, as do most of them, betokening their crispum origin on one side, the ground colour of the sepals and petals yellow, densely spotted with brown on the upper half, and with purple at the base; O. grandiceps is of stellate form, with broad petals and sepals tipped with a pale yellow tint and blotched with brown for two-thirds of their length, base of lip a purple tint; O. præstans, rather similar to the last, but with more numerous brown patches on the petals and sepals, the flower above middle size; O. salmoneum, creamy-white ground freely marked with brown spots, and spotting at the base of the lip; O. eximium, a flower with a bright yellow ground, and a half-circle of a brown tint containing an oblong brown patch in the middle, this is one of the best of the lot; O. Loochristiense has a yellow ground colour, with large patches of brown on all the segments excepting the lip; O. bellatulum, nearly wholly of a rich brown tint with bars of yellow, the lip purplish-brown at the base. O. corallinum, a flower of middle size, with short, broad segments of a creamy-white ground, dotted over distinctly with brown, and the lip is furnished with purple spots. O. hirsutum is of great size, boldly marked with brown on the wide and long petals and sepals; the lip long, and ending in a point, with purple and brown spots on the basal half. Another form of O. Loochristiense, differing from the other in having more white at the base of all the segments; it is comparatively a large flower. O. gratiosum is a flower with a yellow ground-tint, blotched brown, and small purple spots on the lip. The alleged parents of these fine varieties are crispum, triumphans, Pescatorei, and, perhaps, Halli. The 1st prize of 500 francs was awarded, together with a work of art, *à l'unanimité*.

M. C. Vuylsteke exhibited a group of seventy-five Orchids, receiving the 1st Prize, and a table service for twenty-four persons. We noted several fine Odontoglossums, including ioptocon, a dark purple; a nice bit of Cypripedium caudatum, Masdevallias in some variety, including Veitchi grandiflorum, Houtteana, and Lindeni; a fine plant of Cymbidium Lowianum, Miltonia Bleueana, white flower; and M. Empress Augusta, of a bright rosy purple; M. vexillaria virginalis, a very superior white and rose-tinted flower, &c. A nice collection of small-sized and good things.

M. C. Vuylsteke was awarded 1st prize and a Gold Medal for a collection of thirty Odontoglossums, including cuspidatum xanthoglossum, gloriosum crispum guttatum, excellens triumphans, a very fine form; t. maximum, histrix equally so. All small, of trade size. The same exhibitor was awarded 1st prize for a collection of ten Masdevallias, including ignea aurea, ignea majestica, Veitchiana grandiflora, and Harryana splendens.

The finest Cypripedium was Flamingo, shown by M. Hye Leysen. It is a flower generally of a greenish-yellow tint, with purple marking, the dorsal sepal purplish, with a white margin (1st prize and a Silver Medal).

The most beautiful Lælio-Cattleya was shown by M. Hye Leysen. It is a hybrid from L. purpurata and C. Lawrenceana, and in shape and colour it may be said to be fairly intermediate between these species (1st prize and Silver Medal of 1st class).

The best fifty Orchids were those of an exhibitor whose name we could not ascertain, who obtained 1st prize and a work of art. We noted Cattleya Warneri, C. Mendeli in its finest form, C. × Parthenia gratissima, C. Schiellmanniana, various Miltonias, Odontoglossum crispum guttatum violaceum, a handsome form, having a rosy ground-tint; O. Halli leucoglossum, O. Ruckerianum, O. R. superbiens, Mesospinidium vulcanicum grandiflorum, &c.

Messrs. E. Praet & Co., Mont St. Amand, in a collection of twenty-five, showed a Vanda tricolor, a Miltonia or two Cattleya Schroderi, Cypripedium villosum, C. Dauthieri, Odontoglossum Ruckerianum, Cœlogyne cristata, &c., ordinary trade plants (1st prize, together with a work of art).

M. E. Praet & Co., St. Amand, had several small exhibits, usually taking 1st prizes. He had, for example, the best Epidendrum, and in another class the finest Cymbidium Lowianum, and Oncidium sarcodes. The finest Cattleya Mossiæ was that shown by him.

Mr. Van Beerleere, Mont St. Amand, showed groups of thirty and of fifteen Cypripediums. Cool Orchids in quantity were not shown, and numerous classes were not represented.

M. Van Beerleere had the best dozen of one species fit for using in apartments, showing Odontoglossums.

Dendrobiums and Cœlogynes were scarcely represented, and the prizes went to not very fine specimens.

M. Hye-Leysen had 1st Prize for Dendrobium Ballianum, a charming white-flowered species, with the habit and form of flower of D. nobile. The same exhibitor took the 1st award for a large plant of Cypripedium Boxalli furnished with a dozen blooms. He was likewise 1st with an Odontoglossum triumphans, and with an Angræcum sesquipedale with ten blooms—a remarkable number for so small a plant; and also with Cattleya Lawrenceana var. Hyeana, a flower with a deep purple lip. The best Masdevallia, viz., Pourbaixi, an orange-red flower, came from him.

Messrs. F. Sander & Co. showed a natural hybrid Odontoglossum Prince Albert, absolutely new, and flowering for the first time under cultivation. The flower is of the most admired form, with a wide, channeled, and fringed lip, which is white at the apex, and brown at the base; crest fringed and white, and a prominent feature; sepals of a yellow ground tint, with broad brown blotches, the petals showing more of the yellow, and less of the brown colour. The flower is as if varnished.

With the exception of the class for seventy-five Orchids, for which only foreigners could compete, the competitions were open, and good cultivation and fine flowering were the points of chief consideration.

NEW PLANTS.

For a collection of twelve Palms new to commerce, Messrs. F. Sander & Co. were easily 1st, and remarked were small specimens of Kentia Kirsteniana, leaves of a dark-green tint, and obtusely wedge-shaped leaflets; K. Warletiana, with leaflets few and distant; Ptycoraphis singaporensis, a graceful species, with many narrow leaflets on each leaf-stalk, the latter semi-pendent; Linospadix Petrickiana, in general aspect bearing a resemblance to the last-mentioned plant, but the leaflets are broader, and the closed central leaf is bronzy-green; K. Sanderiana, a graceful species, of seemingly rapid growth; Areca Ilsemanni, an erect-growing plant, whose central leaves are coppery-hued, and the leaflets half-an-inch in width, and set 1 inch apart; Rhopaloblaste hexandra, a particularly ornamental Javan species; Linospadix Micholitzii, a broad-leaved species from New Guinea, each leaf divided at the apex; Ptychoraphis Augusta, Licuala Jeanenceyi, and lastly, Calamus Alberti, good Palms, of fine characteristics. In this class a 1st prize fell to Mr. Arthur de Smet of Ledeberg, near Ghent, for a species named Didymospermum porphyrocarpum, of bold habit, and robust build.

The best new Pandanus was shown by Messrs. F. Sander & Co., namely Sanderi, a species of apparently robust habit, leaves of great length, serrated at the edges, and broadly striped with white on green.

The best Juniper of recent introduction was J. Sanderi, a Japanese species introduced about 1896 by Messrs. F. Sander & Co. As seen, it is extremely bushy, but probably when not cut up for propagation, it will assume a rather less dense, and a pyramidal mode of growth. It is believed to be a useful plant for furnishing window boxes, beds in the open, and for pot culture. The habit of the plant bespeaks its thorough hardiness. The colour of the needles is blue-green. The plant was likewise shown by the exhibitors in another section of new plants along with Tsuga canadensis Sargenti pendula, and Pinus Thunbergi variegata. The first-named has the diffuse habit of the type, and the usual inclination of the stem from the perpedicular. It has short dark coloured needles set in a triple row. Other characteristics were not noticeable owing to the small age of the plant. The second plant has branchlets densely clothed with needles, two in a sheath, which change to white when aged. The firm was awarded a 2nd prize and Silver Medal of Class II. for this exhibit of Conifers.

The best new Crotons (Codiæums) distinct, were shown by M. Le Draps-Dom, of Laeken, Brussels, viz, M. Draps-Dom, B. Comte, and Alphonse de Rothschild, all of them possessing entire leaves and bright colouring. The last-named variety received an additional award of 1st prize and Silver Medal of Class II. For the set of three, a 1st prize and a Silver Medal were awarded. The last-named firm won a 1st prize for a plant of Dracæna Janssensii, a white and green-leaved species, with leaves of great breadth.

The finest plant of Anthurium Scherzerianum was shown by Messrs. F. Sander & Co., the spathes measuring 9 inches by 3 inches, and stalks of such a height as to carry the spathe well above the foliage (1st Prize and Silver Medal).

The best new single-flowered Azalea indica, a seedling or a graft, was Madame Osterreith, a very nice crimson-coloured flower, shown by M. J. Vervaene, Ledeberg; award, 1st Prize and a Silver Medal.

The best new double-flowered Azalea indicà was Ledeberg Wonder, shown by the same exhibitor; it was likewise crimson-coloured (1st Prize and Silver-gilt Medal); 2nd was Eug. de Cock, also crimson in colour, from M. Eug. de Cock; awarded a Silver-gilt Medal.

The best new single-flowered variety of Azalea indica obtained from seed was Minister Begerem, shown by M. J. Vervaene, a flower of large size, and of a nice shade of crimson.

The new Azalea indica Haerensiana was shown by J. B. Haerens & Wille, a handsome semi-double rose-coloured flower (1st Prize and Silver Medal of the 1st Class). MM. L. Eekhaute et Fils were 2nd for Azalea Mdlle. Emma Eekhaute, flowers rose bordered with white.

Three seedling Rhododendron rustica were shown by M. C. Vuylsteke, viz., Adonis, white and rose; Patrie, pale lemon-yellow; and Graciende, somewhat like the last in the shade of colour, but of semi-double form.

The same firm of nurserymen showed Anæctochilus Leopoldi, a handsome leaved species or variety, moss-green and black, tesselated with golden yellow lines. They also showed six plants of Kentia Alberti; and exhibiting in Class 120 of this section, they were awarded for three Caladiums a 1st prize, and Silver-gilt Medal for, viz., C. Chas. Vuylsteke, a crimson-coloured leaf with green margin; C. President Petrick, similar to the last but having a wider margin; and C. K. J. Kuyk, a variety with copper-coloured leaves spotted with crimson.

M. de Reusse, frères, of Saffelaere, Ghent, were awarded a 1st prize for Areca robusta variegata, the leaf tints being light and dark green.

A new Holly named Golden King, resembling in form of leaf Waterer's Silver Queen, came from Messrs. Little & Ballantyne of Carlisle.

Twelve small plants of Dracæna Godseffiana were shown in fine condition by Messrs. F. Sander & Co., extremely fine in tint (1st Prize and Silver-gilt Medal).

M. A. de Smet received a Silver Medal, 2nd class, for Anthurium Baron de Bieberstein, a variety with creamy-white spathe spotted with red.

A new Strawberry, Louis Vilmorin, very prolific, was shown by the Brothers Steynaert, Ghentbrugge, a 1st Prize and a Silver Medal was awarded.

Messrs. F. Sander & Co. showed in class 350, receiving 1st prize and a Silver Medal for an example of Acalypha Sanderiana, 7 feet high and widely branched; also twelve plants of Dracæna Sanderiana, and for these they were accorded 1st Prize and Silver-gilt Medal.

Besides showing new subjects in competition, this firm tabled a number of plants, some of recent introduction, as Alocacia Warreniana, Caladium albanense, C. venosum, Heliconia rubricaulis, Gardenia Stanleyana, an old species, rarely seen in flower, and received a Prix d'Honneur.

Clivias were rather numerously shown, and were good for the season, having large heads of flowers, and very vigorous in growth. The best single specimen in a tub was shown by M. V. de Brasschop, of Tronchienne, Ghent. It possessed fifteen flower-heads of fine form and rich colour, and was awarded a 1st prize and a Silver Medal.

CARNIVOROUS PLANTS.

M. Maurice Verdonck, nurseryman, Chaussée de Bruxelles, exhibited twelve Nepenthes of moderate size, including Chelsoni, Outrami, Sedeni, Stewarti, coccinea, Mastersii, and superba (1st Prize and Gold Medal of fifty francs value).

GREENHOUSE PLANTS.

Twenty-five Cape and New Holland plants were shown by M. Georges Fretin, Avenue de la Gare, Meirelbeke, mostly large, and well grown and flowered, varying in height from 3 feet to 6 feet, and proportionately broad. Particularly noticeable were Erica cucullata, a white, minute flower; Diosma alba, Acacia Drummondi, A. verticillata, a big plant, flowered in every part; A. grandis, Pultaenea stricta, Lithospermum fruticosum, a small plant, with flowers of bright blue; Boronia polygalifolia, and others; Brachysema acuminata, Metrosideros stricta, densely flowered, and several Cytisus (1st Prize, and a Work of Art).

The best twelve Cytisus racemosus of large size were shown by N. Léon Chysels, Rue de la Prarie, Ghent, short-stemmed standards, very well flowered. A 2nd Prize, and Silver gilt Medal framed.

For six of these plants on tall stems, 3 to 5 feet, strong, 1st and Enamelled Medal, to M. G. Fretin. The Cytisus, when grown of this form and size, make useful decorative material. Pyramids were likewise shown, but this form of distortion is not to be recommended for imitation.

Twelve Acacias, Cytisus, &c. In the best lot of these plants, we remarked Cytisus racemosus and Acacias paradoxa linearis, a densely-flowered plant; A. p. cordata, with long racemes of white flowers; A. lineata, A. lancifolia, &c. 1st, M. G. Fretin, 1st prize and Gold Medal.

The finest six plants of Metrosideros on tall stems came from the same exhibitor; they were profusely furnished with their bottle-brush-like flower-heads (1st Prize and a Medal).

The finest pair of plants of an Acacia were A. verticillata, shown by Mr. C. de Loore, Meirelbeke (1st Prize and Silver Medal).

Mr. C. de Loore showed the best couple of Choisya ternata, standards of 4 feet in height, furnished with crowns 2 feet in diameter (1st prize and Silver Medal, 1st class).

The finest grown Clianthus magnificus, measuring 4 feet by 4 feet, was that shown by M. Van Renterghem-Rombout (1st prize and Silver Medal, 1st class).

Boronia elatior is a plant that was often exhibited, and single plants, showing long-continued, careful cultivation, were shown.

The finest Pimelea was P. spectabilis, a plant 5 feet high and 4 feet in diameter, shown by M. L. Van Houtte (1st Prize and Silver Medal, 1st class). The same exhibitor had a good Erica Cavendishiana, that brought a similar award.

The finest Medinilla magnifica came from M. K. J. Kuyk, a very vigorous and massive plant, with strong racemes of flowers (1st Prize and a Silver Medal). The next best was shown by M. J. Borllens, Ledeberg, were bloomed, but less vigorous (2nd Prize and Silver Medal of 2nd class).

GREENHOUSE PLANTS OF COMMERCIAL SIZE.

Cold greenhouse plants were largely shown, such as those we have named, and Brachysemas, Correas, Diosmas, Eriostemons, Hydrangeas, Genista scoparius Andreanus, Leptospermum, Polygala, Boronias, Chrysanthemum frutescens, but little that would be of interest to our readers. The Ghent nurserymen are growing these Cape and New Holland plants extensively, and we shall doubtless see them re-introduced to general cultivation in a few years. Nothing can well be more beautiful for the decoration of the cool houses during the spring and early summer months.

AZALEA INDICA IN BLOOM.

For a collection of thirty-six plants of Azalea indica, 1st Prize and a Work of Art to M. J. Vervaene, Ledeberg, for neat examples 1¼ to 2 feet high and in diameter, capitally flowered, as were indeed the principal exhibits of Azalea indica.

M. Em. Vercauteren, of Mette, showed sixty Azalea indica, in small, round-headed examples. Very nice were Vander Cruysen, Victor Suvart, Cocarde Orange, Dame Melanie, J. Veitch, Jos. Vervaene, Bernard Andrea, Jean Peeters, Chicago, &c.; a very beautiful group of plants (1st Prize and a Gold Medal).

For a collection of 100 Azalea indica, 50 to 60 centimètres in diameter, there were several competitors, and the 1st Prize and a valuable work of art fell to M. Maekhout van Melle, Mont St. Amand. The plants were as well bloomed as possible, and nicely assorted as regarded colour. The varieties Coppe, A. Borsig, Marie Planchon, Ceres, Madame van der Cruysen, punctulata, Princess Louise, Duc de Nassau, and Apollon took our fancy, but selection was all but impossible where all were so good. Messrs. F. Sander & Co. were 2nd in this class, by a very slight difference, not in quality probably, but in the choice of colours. We noted Minister Léon de Bruyn, Helène Chelman, Hermione, Camille Vervaene, and President A. Van Geert.

M. Seraphin Aelvoet, of Wendelghen, was an exhibitor of sixty Azalea indica, small plants, including single and double flowered varieties, securing 2nd Prize and a Silver-gilt Medal.

Another sixty Azalea indica were those shown by M. Maenhout van Melle, very suitably assorted as regarded colour (2nd Prize and Gold Medal).

Semi-double, striped, and spotted Azalea indica were shown by M. K. J. Kuyk, namely, Madame Eulart, Madame Luvins-Spae, Arlequin, Pharailde Mathilde, Daphne, Madame Seidel, Eborina flore pleno, and others, twelve in all.

Mr. Kuyk showed a dozen single-flowered Azalea indica, and the varieties Media, versicolor, Neige de Cerise, Baronne de Vries, Reine Marie Henriette, Ceres, and Apollon were specially pleasing.

Then came a great number of classes of Azaleas, and in certain tints, and double and single flowers, low and tall stems, for which prizes were duly awarded; but the mere mention of exhibitors' names and addresses, and names of varieties, would occupy too much of our space. The great number of varieties, unknown or but little known on this side of the water, should stimulate our cultivators to grow them, nothing being more showy, yet delicate, than the colours of the newer varieties. We will name only one, Chicago, of which several big groups were shown, M. E. Vercauteren taking 1st Prize.

The courteous and indefatigable Mr. K. J. Kuyk was extremely fortunate in winning prizes with his Azaleas, and he showed in many classes. His single-flowered variegated varieties (twelve) gained him one 1st Prize and a Medal. In this group we noted Louise Van Houtte, Professor Walter, Dame Melanie, Madame Aug. Van Geert, and Reine des Amateurs.

Messrs. Haerens & Wille, at Somerghem, were winners of a 1st Prize and a Medal in double-flowered variegated Azalea indica.

A collection of 100 Azalea indica grown as low standards, which likewise consisted of the finest modern varieties, all of which were densely flowered, were shown by M. E. Vercauteren, of Mette. 1st prize and 250 fr. Good were Comte de Asambord, J. J. D. Llewelyn, Benjamin Sillence, Unica, Pharailde Mathilde, Johann Burscher, Perle de Ledeberg, Pres. Oswald de Kerchove, Madame J. Vervaene, Marie Vervaene, and many more very beautiful.

1st Prize and Silver-gilt Medal to P. Van Renterghem-Rombout, 547, Mont St. Amand, a very choice lot of standard Azalea indica, including Hermosa, a fine double rose; Chas. Lieven, fiery red, semi-double; Vervaeneana, Madame de Greve, Niobe, Pluto, a deep set, &c.

Azalea mollis and Ghent Azaleas were numerous and well grown, especially standards of the former, with 3 to 6 feet stems.

Ghent Azaleas, as bushes and low standards, flanked the central grass avenue, and contained most of the new varieties. These were shown by M. Jean Bracke-Beyst, Loochristy, near Ghent. They were an extremely floriferous lot of plants.

1st Prize and Gold Medal to Arthur de Smet for twenty Azalea mollis, in nearly all varieties of colour, and 4 to 6 feet high, were particularly showy.

M. David Wulteputte, of Loochristy, showed Azalea mollis as low standards, 2-feet stems, splendidly bloomed.

1st Prize and Silver Medal, 1st class, to Victor Vandewight, Loochristy, for Spiræa floribunda, a pretty white species.

RHODODENDRONS.

In this division there was provision made for numerous classes of Rhododendrons, which, however, were not well filled; in fact, Rhododendrons were few throughout. Some small plants were shown by Mr. David Wulteputte, mostly English hybrids.

Mr. K. J. Kuyk, who is the successor to M. Aug. Van Geert, received an Award of a Silver-gilt Medal for a group of R. Prince Camille de Rohan, a light-coloured variety, with a smallish, compact truss, and of free-flowering habit. Should make a good forcing variety.

CACTI.

Cacti were well represented at the exhibition, and five 1st prizes were gained by Frantz de Laet, Contich, near Antwerp, for Cacti and succulents; a work of art and 100 francs for ninety Cacti, Phyllocacti, Epiphyllums, &c.; Gold Medal for twenty-nine Agave, Aloe, and other succulents; Silver-gilt framed Medal for twenty-nine Cacti; Silver Medal of the First Class for twelve, and a Silver Medal for a lot of 200 Cactus seedlings. Specially remarkable were Cereus fragriformis, covered with over 200 flowers; C. lividus, 2 mètres high, and many others, all well cultivated, without a spine spoiled. Echinocactus Wislizeni, 2 feet across—a splendid plant; E. pilosus Stainesii; four E. ornatus, 1 foot across, all fine plants; E. texensis, 1 foot, with eight splendid pale yellow flowers; and a lot of other plants, all showing successful culture. The 200 Cacti seedlings also were much admired.

FOLIAGE PLANTS.

These formed features as groups, and as a mask to the walls (canvas) of the building. Being mostly contributed by the trade, specimens conspicuous for very large size were not observed, although much that was very creditable to the trade was seen on all sides.

As coming from M. DE SMET FRERES, we remarked a grand plant of Cycas tonkinensis of perfect form, furnished with a full crown of leaves, and of a height of 6 feet. The same exhibitor staged Livistona brachypoda, a compact-growing species, with broad, much divided leaves, obtaining a 1st prize in each instance, as also for an example of Chamærops humilis argentea, of a height of 6 feet, and very dense in growth.

M. K. J. KUYK exhibited a pretty lot (twenty) of Cocos Weddelliana. Dracæna Doncetti were shown as large and half specimens in cases, showing superior cultivation. One large exhibit and several small ones of climbing Asparagus. We noted A. comorensis, A. medius, A. scandens deflexus, A. virgatus, A. Brousonetti, A. Sprengeri, and A. plumosus nanus.

One good collection of twenty-five species of Ferns contained plants of Aspidium caryotæfolium, Pteris Wimsetti, P. Ouvrardi, Asplenium lucidum, Todea sps., Microlepia hirta cristata, Cibotium regale, C. princeps, Nephrolepis Giesbrechti, N. davalloides multiceps, Alsophila Moorei, and various Adiantums.

Of the striking-looking Dracæna Massangeana there were several exhibits, in large and small examples, and in every instance the plants were massive in habit and perfect in shape and in leafage. Extra good plants of Aralia Sieboldi, and A. S. variegata in dozens were noted, stems and foliage of great robustness. Dracæna Bruanti was well shown, also Pandanus Veitchi, not growing in very large pots, but yet furnished with strong foliage, having the variegation well brought out. Of this plant many exhibits were noted, some being of the customary commercial sizes. Araucaria excelsa, a plant made much use of on the Continent, was extensively exhibited from plants 1¼ foot high upwards.

The exhibitor of the finest dozen, M. K. J. KUYK, had A. cordata, A. Leopoldi II. (excelsa var.), A. albo-spica, A. viridis glauca, &c. The second best dozen, to which many persons would accord the first place, were shown by M. GEORGES FRETIN, and it included A. Cooki, Professor Mulleri, a species with upward-turned branchlets, very distinct; A. Cunninghami excelsa, A. C. glauca, A. Rulei, A. excelsa glauca robusta, A. Joseph Napoleon Baumann, A. Roi des Belges, an elegant variety of excelsa, and A. Bidwilli.

MISCELLANEOUS.

The BROTHERS DE GRAAF, of Leyden, exhibited Narcissus in considerable variety, including Barri, Poeticus, Leedsii, incomparabilis, Polyanthus, intermedius, bicolor, and Empress forms—an excellent representative collection. A Gold Medal was awarded for this lot. Messrs. BARR also exhibited in this section.

M. J. F. VERVAENE-VERVAERT & Co., Silver Medal of the 1st class for seedling Anthurium, new, of 1899, dull pink in colour.

Messrs. ROBERT P. KER & SONS, Aigburth Nurseries, Liverpool, showed a great number of plants of their strain of Hippeastrum, which resemble in most points those we are accustomed to see at the Royal Horticultural Society's meetings. They were awarded 1st Prize and Work of Art by acclamation.

A collection of useful and injurious insects were shown in glass cases by the *Tuin-en Landbouw*. Just what we require in England in all schools of horticulture. Each insect was designated by its vernacular and scientific name.

A few exhibits of twenty-four small plants of Citrus sinensis, profusely laden with ripe fruit, were remarked, their height being 2 to 2½ feet, and the form a columnar bush. The best were from M. E. LOSSY, Mont St. Amand, and the next best from M. JULES LOSSY, Cnudale.

MANCHESTER & NORTH OF ENGLAND ORCHID.

APRIL 27.—At a meeting held in the Coal Exchange, Manchester, on the above date, there were present Messrs. G. Shorland Ball (Chairman), G. W. Law-Schofield, A. Warburton, D. B. Rappart, P. Weathers, J. Cypher, R. Johnson, W. Holmes, and J. Mills (Hon. Sec.).

G. SHORLAND BALL, Esq., Wilmslow (gr., Mr. Gibbons), showed Cymbidium Ballianum (First-class Certificate); Odontoglossum Coradinei (Award of Merit); O. triumphans (Award of Merit); Phalæopsis Luddemanniana (Award of Merit); also a group of plants for which he was awarded a Silver Medal.

THOMAS STATTER, Esq., Whitefield (gr., Mr. Johnson), showed Lælia latona (Award of Merit), Epiphronitis Veitchi (Award of Merit), Cymbidium eburneo-Lowianum (Award of Merit), Eulophiella Elisabethæ (Award of Merit), and a group of plants (Silver Medal).

SAMUEL GREATRIX, Esq., Whalley Range (gr., Mr. MCLEOD), exhibited Cypripedium Chapmani (First-class Certificate), Lycaste Imperator (Award of Merit), &c.

J. LEEMANN, Esq., Heaton Mersey (gr., Mr. Edge), had Cattleya intermedia (Award of Merit), C. Schilleriana (Award of Merit), and a group of plants, for which an award of a Silver Medal was made.

A. WARBURTON, Esq., Haslingden (gr., Mr. Lofthouse), obtained a First-class Certificate for Cattleya Mendeli.

H. GREENWOOD, Esq., Haslingden (gr., Mr. Gill), showed Dendrobium nobile giganteum, H. Greenwood's var. (First-class Certificate), and Odontoglossum Hunnewellianum maximum (First-class Certificate).

Mrs. BRIGGS-BURY, Accrington (gr., Mr. Wilkinson), showed Cattleya Mendeli, Quorn House var. (First-class Certificate), and C. M. Duchess of York (First-class Certificate).

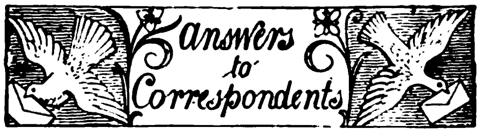
Messrs. SANDER & Co., St. Albans, Herts, were awarded a Cultural Certificate for a plant of Cattleya Schroderæ; and an Award of Merit for Cypripedium insigne, vars. Chantini × Chamberlainianum.

Messrs. CHARLESWORTH & Co., Heaton-on-Mersey, showed Cattleya Schroderæ Heatonense (First-class Certificate), Cypripedium Hyeanum (Sallieri Hyeanum × Spicerianum) (Award of Merit), and C. Manselli (Award of Merit).

TULIPA DIDIERI ALBA.—We hear that this rare Tulip is now in full bloom at Ard Cairn, Cork. In the bud state it is described as equal to a Niphetos Rose, with a frond of Maiden-hair Fern. The blooms are all perfumed similar to Sweet Pea.

ENQUIRY.

CROWN IMPERIALS and Double-flowered Daffodils, usually profuse in bloom, come up this year with abundant leaf and very few flowers. Can it be explained? They grow in a border somewhat traversed by tree-roots. *W. T., April* 29.



Answers to Correspondents

ANTS IN ORCHID-HOUSES: *Veritas.* Ants are better got rid of from the Orchid-house, and one means is to place in their runs a bone in a pan, and as often as the bait has attracted a sufficient number take it outside and pour boiling-water on it. Anything which attracts them to a centre may be used to trap them, and if they can be found in the house in numbers, and where killing them inside the house can be done without injury to the plants, boiling water may be poured on them.

BEETLES: *Windsor.* Next week.

CORRECTION: Our correspondent, "R. D.," wishes to correct a statement in his note on p. 258, upon the Vandas at Gunnersbury Park. There were 160 or so racemes of flowers, not this number of single blooms.

CUCUMBERS, TOMATOS, AND BEGONIAS: *R. W.* The Tomato and Cucumber plants have been attacked by fungi common in forcing-houses. The fungi may be temporarily checked by spraying with potassium sulphide (½ oz. in each gallon of water), or Bordeaux Mixture. The real reason for the trouble is that the air and moisture of the house are unsuited to the plants. Have you not too severely forced the plants? Endeavour to obtain a more vigorous growth, by using a little less fire-heat, by the admission of fresh air on all occasions when the conditions of the weather outside are suitable, and by securing as much light to the plants as possible. The injury to the Begonia is caused by a mite, and may be remedied by dipping the plants in Tobacco-water or by treating them with Tobacco-powder. Further particulars of this pest to Begonias may be found in the *Gardeners' Chronicle* for November 9, 1895, p. 544, and November 16, 1895, p. 586.

DAFFODILS: *G. K.* They have been allowed to suck up some aniline dye. We should not advise you to buy any bulbs.—*A. C.* You should get Burbidge's *The Narcissus*, L. Reeve & Co.

IMANTOPHYLLUM: *G. B.* Yes, there are many varieties.

LOW TEMPERATURE: *R. F.* The winters of 1879, 1880, and 1881, were remarkable for hard frosts throughout England, Wales, and Scotland, and numerous exotics of reputed hardiness were either killed or badly injured. On December 4, 1879, 12° below zero, or 44° of frost, were noted in Peeblesshire.

MANURE: *Windsor.* What you send is sulphate of iron or green vitriol. It is useful as a manure, and is specially recommended for Roses. A quarter of a pound to a gallon of water.

MISLETO ON OAKS: *H. I. R.* The species found on Oaks and Chestnuts in Italy is Loranthus europæus. That which grows on Apples, Maples, and other trees is Viscum album. A third species, Viscum laxum, is said to grow on Pinus sylvestris, in the Valley of Non.

MUSCAT OF ALEXANDRIA GRAPE-VINE: *Anxious One.* The bunches present the appearance of having been checked by cold. Perhaps you do not close the vinery early enough in the afternoon.

MUSTARD IN AN HOUR: *Subscriber.* Nonsense.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—T. N., Epsom.* 1, Berberis Darwini; 2, Berberis, seedling from Darwini apparently; 3, Forsythia viridissima; 4, Skimmia japonica; 5, Cedrus, perhaps C. atlantica.—*A. A. Dalzell.* Leucothoe axillaria.—*Molesey.* Pyrus salicifolia.—*A. M.* 1, Oxalis Ortgiesiana; 2, Marjoram; 3, Thuya orientalis variety; 4, Juniperus virginiana variety.—*R. G. J.* Tritonia crocata, Cape of Good Hope.—*J. L.* 1, Skimmia japonica; 2, Spiræa prunifolia variegata; 3, Acorus gramineus variegatus.—*W. D.* The Codiæums (Crotons) are—1, superbum; 2, Laingi, or Heathi elegans; 3, Queen Victoria; 4, Disraeli. We cannot name the Rhododendrons from the flowers sent.—*F. O.* 1 and 2, Dendrobium thyrsiflorum; 3, Dendrobium cariniferum; 4, Dendrobium Boxalli; 5, probably Dendrobium Devonianum — flower withered.—*J. E.* Albuca species (probably minor), but we cannot be sure of the species without seeing leaves.—*W. and S.* The specimen was withered. It is best to send specimens of Roses to a nurseryman who grows them largely. They can be compared by him with living specimens.—*L. B.* The miserable scrap was dried to tinder when we received it. It is probably the Snowy Mespilus, Amelanchier vulgaris.—*No Letter* (received in a new year's card box). The scented Pelargonium is P. crispum, the other plant Sedum Ewersii.—*C. S., Ipswich.* 1, Celsia cretica; 2, Asplenium bulbiferum biforme; 3, Hoya carnosa; 4, Adiantum formosum; 5, One of the Daturas, but not recognisable without flower; 6, Asplenium bulbiferum.—*J. S. U.* Skimmia japonica.—*G. W. C., Aberdeen.* The variety of Cattleya Schroderæ is very distinct, the other species also good. The rose-tinted bloom is Vanda Parishi Marriottiana, the small Odontoglossum a variety of O. × Andersonianum.—*F. P.* Ornithogalum nutans.—*A. R.* 1, Phalaris arundinacea variegata; 2, Aubrietia deloides purpurea; 3, Corydalis lutea; 4, Lastrea species, send mature fertile frond; 5, Send in flower; 6, Sedum rupestre; 7, Polypodium glaucum; 8, Cyrtanthus species, impossible to say which without flowers: 9, Adiantum formosum; 10, Polystichum angulare proliferum.—*J. A.* Eriobotrya japonica (Japanese Medlar).

NURSERYMEN'S PROTECTION SOCIETY: *E. J. A.* You had better communicate with the Nursery and Seed Trade Association, Ltd., 30, Wood Street, Cheapside, London, E.C.

PELARGONIUMS: *F. E.* We cannot undertake to name florists' varieties. Send specimens to some grower.

ROSE MADAME LOUIS CARIQUE: *S. S.* This variety is mentioned in Max Singer's *Dictionnaire des Roses*, where it is described as a H. P., of average size, full, and in colour vivid carmine.

STRAWBERRY-LEAF DISEASE: *J. G.* Your leaves are attacked with the fungus Sphaerella Fragariæ, figured in *Gardeners' Chronicle*, June 28, 1890, p 799. A weak solution of the Bordeaux Mixture will be found useful in this case, and the best time to apply it is once in every two weeks when the crop has been gathered. The dressings may be continued until September.

TULIPS: *S. W.* We should be inclined to blame the mice or wireworms for the damage done. Can you send a few bulbs for our inspection?

COMMUNICATIONS RECEIVED.—F. M.—E. C.—W. B. H.—M. D.—A. C.—M. M., Geneva.—H. I. R., Florence.—H. H. H.—Sir J. L. — C. B. P. · J. Chilcott — R. Milne-Redhead. — T. Roberts.—W. E. G.—John Russell.—Visitor.—D. T. F.—Rev. Hilderic Friend (next week).— H. H.—A. C.—Sir C. S.—T. C.—Lord I.—J. K.—C. R. F.—G. G.—E. C.—R. W. A. – C. T. D.—A. C. F.—C. S. F.—E. Branch, Windsor.

SPECIMENS AND PHOTOGRAPHS RECEIVED WITH THANKS—R. C. H. (many thanks; not suitable for figuring).—A. C. (many thanks; useful).—J. George (very fine plants; we have, however, figured similar ones on many previous occasions).

(*For Markets and Weather, see p. x.*)

THE
Gardeners' Chronicle
No. 646.—SATURDAY, MAY 13, 1899.

THE CLYDESDALE ORCHARDS.

At a recent meeting of the Scottish Horticultural Association held at their Rooms in Edinburgh, Mr. Wilson, of Murdostoun, Lanarkshire, himself a large grower for market, gave an account of the orchards of Clydesdale.

Mr. Wilson began his lecture by paying an eloquent tribute to the picturesque beauty and fruitfulness of the Clyde valley, the abundant crops yielded by the orchards, uninjured by surrounding manufacturing and commercial establishments; the huge boughs of the fruit trees overhanging the hedges near Braidwood, the palatial homes of the Grahams. The aspect and the soil of this locality are specially suited for fruit growing.

A few of the more notable orchards that stand out prominently for high cultivation are Cozy Glen, Dalzell, Brownlie, and Garrion. Some of these orchards receive as much as 40 to 50 tons of farmyard manure a year. Few or no weeds are visible, and almost fewer signs of starving the land or slovenly culture can be seen in Clydesdale. On the other hand, preserve and jam factories abound in all directions. Thus, the proprietor of an orchard can readily convert the perishable, soft fruits into commercial commodities within easy distance.

Most of the growers have added Tomatos, florist's flowers, and nursery plants as well as vegetables to the products they cultivate. Dealing in poultry, milk, butter, and pigs are also commonly engaged in. Young trees are also preferred to old ones, and though several old orchards are still to be found in Clydesdale, some few years ago the fruit from an old orchard at Carsethorn realised the sum of £1000, the orchard being 30 acres in extent.

Cropping between the trees, unless for cleaning purposes, is generally condemned. Growers are also careful to secure the best skilled labour obtainable for such orchard-work as pruning, digging, and planting.

Lord Hamilton of Dalzell has enclosed 10 acres with wire-fencing, and made colossal runs for 300 fowls, for the double purpose of benefiting both fowls and fruit-trees and bushes.

Clydesdale has long been famed for its fruit, and at no period has the industry been engaged in with more spirit and more money invested in it, and more skill shown, than is the case there to-day. Only through skilful culture and carefully disposing of the best fruit can success be realised. The people are awaking to the vital importance of fruit, and the demand grows and ready markets are always open.

The proprietors of the land are mostly the large landlords of the district, between whom and the tenants the kindest feelings and pleasantest relations exist. Among these, the following are the chief:—Lord Belhaven, Wishaw; James Hamilton Houldsworth, Coltness; Lord Hamilton, Dalzell; Lord Newlands, Mauldslie Castle; James Scott, Garrion; Henderson Hamilton, Dalzell; Major-General Lockhart, Cambusnethan; their palatial homes nestling more or less close to the comfortable dwellings of the fruit-growers. A visit to Garrison Bridge at the annual sales, or to any of the commercial centres, will quickly convince anyone of the business capacity of these hard-handed, clear-headed sons of toil. And the growers are as expert in handling the spade and pruning-knife as in driving bargains. Gooseberries, for example, having special treatment in Clydesdale, abundance of young wood being left unshortened, carry immense crops of fruit. The gatherers of Gooseberries are also experts, equal to gathering from 3 to 4 cwts. a day, and earning from 2*s.* to 3*s.* 6*d.* in wages.

As to manures, some apply it annually; others every second, third, or fourth year. Most of the growers prefer farmyard, others artificial manure. Two of the best professional growers, Mr. Deans, of Garrion Towers, and Mr. Angus, of Dalzell, strongly recommend gas-lime and bone-meal, the lime to be exposed a year before applying it. Mr. Deans applies bone-meal in the spring, at the rate of one ton per acre, with grand results to fruit-trees and Gooseberries. The fruit on the 10 acres of the Dalzell orchard was sold on the trees for £321, being an average of £32 per acre. Surface-mulching instead of digging has not answered in Clydesdale; and in orchard-cultivation the digging-fork has almost superseded the spade.

The Kinds of Fruit Grown.

Some thousands of acres in Clydesdale are under Strawberries, and the prices given for the fruit last year ranged from £30 to £38 a ton, a crop from three to five tons per acre being the average. Garibaldi and Elton Pine are still favourite varieties, though the new variety, Royal Sovereign, is making progress. The plants are mostly grown in 4-feet beds, and they are allowed to stand for five years. This Clydesdale fruit follows closely on the heels of the English supplies. Gooseberries are second to Strawberries in commercial importance, and Whitesmith, Red Warrington, and Sulphur are the leading varieties. Early Kent, Crown Bob, Lancashire Lad, and Whinham's Industry, are also popular. Gooseberries range in price from £8 to £12 per ton, and an acre four years planted yielded last season 4 tons 2 cwt.

This is Mr. Wilson's short selection of Apples complete: Dickson's Ringer is the best for cold districts; Cambusnethan Pippin, Stirling Castle, Beauty of Murray, Ecklinville, Cellini, Fulwood, Norfolk Beaufin, and Lord Suffield.

Pears again nearly all do well, particularly Williams' Bon Chrétien, Moor Fowls-egg, Beurré Hardy, Beurré Diel, Marie Louise, Thompsons, and a few other varieties.

Of Plums vast quantities are grown for marketing and preserving. Victoria, Kirkes, Coe's Golden Drop, Magnum Bonum, Jefferson, Orleans, and Pershore, being the favourites. They are mostly grown as pyramids or bushes, and kept in a fruitful state by lifting and root-pruning.

Currants, either red or white are not popular fruits. The red and white Garrion Tower Currants have been so well grown as to command prices of from £16 to £18 per ton. There is not much demand for Cherries, though the Morello does exceedingly well.

Raspberries are rising in popular estimation, Fillbasket, Superlative, and McLaren's Prolific being the favourite varieties, the best crops being obtained in most instances from land that is mulched with manure and not dug yearly.

Black Currants do well, but the Currant-bud mite has proved a sore trial to the cultivators, and, so far, it has resisted all remedies. Mr. Wilson recommends frequent planting with clean young stock, bought at a distance. The Clydesdale growers mostly plant varieties which they distinguish by the names green and brown-budded.

The secret of success, said the lecturer, consisted of brains, energy, soil of the best, a hopeful disposition, and indomitable perseverance. The crazes for cheapness, the effects of foreign competition, of high rents, rates and taxes, the cost of manure—all tended to make success more difficult every year. Still, the great home industry of fruit-growing in Clydesdale grows and expands.

The fruit despatched in 1896 by railway amounted to between 3000 and 4000 tons; and by road for short distances, 300 tons; of Strawberries, 200 tons; and Gooseberries, 350 tons; and Plums, Apples, and Pears in enormous quantities were sent away.

So far as sewage has been used in fruit-growing in Clydesdale, it seems to have been successful. Mr. Wilson concluded his paper with a few statistics that should fill fruit-growers with hopefulness for the future.

Some years ago a grower set aside 25 acres of his best land for growing Strawberries, and McLaren's Prolific Raspberries. He dressed it with 60 tons per acre of farmyard manure. The returns last year from this land reached £1,950. True, the expenses, labour, rent, rates, &c., have to be deducted from this big gross sum, but surely enough would remain to satisfy the most ambitious, after all the claims of capital, labour, and skill had been abundantly satisfied. *D. T. F.*

ORCHID NOTES AND GLEANINGS.

DENDROBIUM WARDIANUM ALBUM.

The colours of the typical D. Wardianum are so bright, and the dark blotches on the labellum so distinct, that an albino form is very remarkable. The variety candidum is pure white with more or less traces of the dark-coloured blotches at the base of the yellow disc.

D. W. album, in which no trace of the dark markings appear, first flowered in the Downside collection, and later, but very rarely in other gardens; a fine form of it being figured in *Lindenia*, ix., p. 73, as D. Wardianum Lindeniæ. An equally good example of it has now bloomed with H. Cary Batten, Esq., Leigh Lodge, Abbot's Leigh, Bristol, the plant being a newly imported one with seven strong leading growths. The flower sent is pure white, the only colour present being the orange disc. *James O'Brien.*

Vanda teres.

This beautiful Orchid is making a fine show in the Cattleya-house at Parkfield, Worcester. The plants are cultivated on teak rafts placed at the end of a span-roofed Banana-house, where they are exposed to all sunshine. They are heavily syringed throughout the summer, but are kept drier during winter. The two largest rafts bear over forty spikes of bloom, and the others are equally well flowered. Altogether there are over 200 spikes. They vary both in size and colour. Some of the flowers are very light, being nearly pure white, and one variety has especially large and dark-coloured blooms. There are some blooms open at most seasons of the year. V. Hookeræ succeeds under the same conditions, but does not flower so freely. Epidendrum bicornutum, suspended from the roof in pans, without any shade, flowers from every young bulb.

In another house Vanda insignis and suavis are flowering well. Eulophiella Elisabethæ has two spikes, with twenty-five flowers and buds on each. *S. W.*

WHEAT AND TULIPS.*

(Continued from p. 275.)

THE GARDEN TULIPS.—The introduction of these to European gardens is, thanks to the sensation they caused from the first, tolerably well known. When Augerius Ghislenius Busbequius, the ambassador of the Emperor Ferdinand I. to the Sultan, in 1554, arrived in Turkey, he saw flowers of these varieties for the first time in a garden between Constantinople and Adrianople.

The origin of our word Tulip is traced from the Persian "Dulben," the Nettle-fibre cloth (Urtica dioica), such as the Turks bind round their fez, and this head covering resembles the cup of the flower. The Turkish name of the flower is "Lale." It is probable that one or another Tulip may have flowered in Venice at an earlier date. As Professor Cohn informed the author, there is a large picture in the Hof Museum of Vienna, by Vittore Carpaccio (scholar of Giov. Bellinis, 1522), portraying Christ surrounded by angels, on the arch of which flowers of Leucoium, Narcissus pseudo-Narcissus and yellow and red Tulips can be discerned. The flowers are, as I have myself remarked, so indistinctly drawn that it is impossible to identify them with certainty.

We are then told that C. Gesner, in 1559, saw the first garden Tulip in Europe outside of Turkey, in Heinrich Herwarth's garden at Augsburg, and in 1561 he wrote a description of it; and this species was none other than our present T. Gesneriana. It is very probable that this Tulip was raised from seed which Busbequius, who had greatly enriched European gardens, had either brought or sent home; and there is nothing which could render that unlikely, excepting the brief period of time—1554 to 1559.

It is known that seedling Tulips flower the third year, and in four or five years this circumstance is of common occurrence. But the Tulip had got sooner into the hands of the Dutch than of Clusius, for we read that, in 1570, it had got to Mecheln (Malines), the third centre of distribution; and the apothecary, J. Muler, concocted a preserve of the bulbs with sugar, which he found much superior in sweetness and flavour to that made from Orchid tubers!

In the year 1577 a red-flowered Tulip was seen in Brussels for the first time, from the seed of which Boisot and several "*nobiles matronæ*," raised variously-coloured progeny. From this Boisot seed sprang our Tulipa Gesneriana, bulbs of which bloomed at Frankfort in 1590.

Independently of Clusius, the Tulip had already reached Holland, for it is related that the Amsterdam apothecary, Wallich Zieuwertsz, to the great astonishment of everyone, had some in flower. When the celebrated Clusius removed to Leyden, he took some of these Tulips and other rare plants, such as Scilla peruviana (which sold for 40 florins per root); the first Lilium imperiale (Crown Imperial), valued at £7; and other plants, which no one else possessed, and which were not to be purchased for any money. In 1590 we find this T. Gesneriana by Jan von Hoghelande of Leyden, and by Prediger Joan de Jonghe of Middleburgh in 1596.

As money could not buy Clusius' plants, it was only natural that people should form a plan to steal them, which was done by night, the finest and best being taken; whereat, it is related, he lost heart and energy. Having stolen the bulbs, the thieves made every effort to increase the stock of them by sowing seeds and in other ways, so that it was asserted that the seventeen provinces of Holland were filled with them.

In England, the introduction of the garden Tulip is traced to Clusius, who sent some bulbs from Vienna between the years 1578 and 1582.

We learn from the *Biographia Britannica*, vol. iv., p. 2462, in instructions from Hakluyt the elder, printed for the use of English merchants, concerning articles of commerce in Turkey, "and now within these four years there have been brought into England from Vienna in Austria divers kinds of flowers called Tulipas; and those and others procured thither, a little before from Constantinople, by an excellent man called M. Carolus Clusius."

According to G. Kraus, the Tulip reached Montpellier in 1598, and in other towns, as Aix in Provence; in 1596 it was found at Lucerne, and gradually spread all over central Europe.

At one time it was believed that the Tulip owed its numerous colour variation to good culture in the Netherlands, and that in its eastern home red and yellow varieties existed. But this is an error; for, according to Clusius, the seeds he received from Busbecq produced at once a number of varieties, a circumstance that could not have occurred had the Turks possessed only two varieties. That the varieties were many is proved by two Turkish MSS., secured by Diez, and now in the possession of the Berlin Library, one of which he completely translated into German, and of the other only a portion.

The first of the two MSS., entitled *Die Wage der Blumen* (The balance of flowers), was written by the sheik Mahammed Lalizari, who lived under the Sultan Achmed III. (1703-1730), and more directly under the great Viziriate of Ibrahim Pascha (1718-1730), and for whom the MS. was written, which is proved by the remark on the first page where he says that Ibrahim caused him to write it. Lalizari stood well at the court of the Sultan, and received from the latter the cognomen, Schukjufé Perweran (kenner of flowers). This little work of Schukjufé Perweran was carried out with tolerable thoroughness under two headings, of which the first described the twenty properties of beauty, and the second gave directions for cultivating Tulips from bulbs and seed.

A concluding chapter treats similarly of the yellow Narcissus. A number of varieties of Narcissus and Tulips are mentioned, some casually, and others as affording examples, many of them being designated by, to us, very familiar names. The second Turkish MS. carries the title "Amenity and Beauty," and consists of a systematic catalogue of various sorts of plants, affording the names, the country of origin of the seed, and description of the flower, but never stating which kind of plant is intended, but which Diez believed to be a byblœmen Tulip. As the author mentions 1,323 varieties, and describes seventy-four fully, an idea may be formed of the variety of the Tulip culture in Turkey in that age. And further, Diez calls attention to the fact that "the twenty rules of beauty" agreed in their limitations with those current in all civilised European countries, with a few exceptions in particulars. He alludes in this matter to the clear and precise statement of the same by Philip Miller, and draws the conclusion that these rules at the introduction of the Tulip formed the foundations of its cultivation in Europe. The only difference in the rules consisted in the Turkish Tulip having a pointed petal, whilst Europeans preferred a rounded one; and, in fact, all of the original Tulips brought out of Turkey, as is seen in Clusius' drawings, belonged to this category.

To-day, in Holland, Tulips are divided into two classes—selfs, or Mother Tulips (breeders), (French colours), and variegated or broken (French Paragons); and these are again divided into two principal sub-classes, Bizarres with yellow grounds, and a variety of markings, and Flamands, which have white grounds; and when the variegated markings are of a violet tint, they are known as Bylœmens, and when these are red they are designated Roses.

The several coloured Tulips, the so-called Masquetrines of the old French nomenclature, were never held in any great esteem in Holland.

All the celebrated old varieties, as Semper Augustus, Admiral Liefkens, Gouda, &c., of which coloured drawings still exist, were simply "byblœmens" or "roses."

The first double Tulips appeared about 1665, which the Count finds mentioned by Vallot as T. lutea centifolia; another, called Sol, mentioned by Tenzel, 1690, had 24 petals; and another, Solo Sicut Sol, with 200 petals; which he said he should value more than Semper Augustus; and others are mentioned under various names, so that double Tulips began to appear in Europe at rather early dates.

The so-called Papagie Tulips (Peacock vars.) appeared towards the end of the 17th century.

We may in an early issue of the *Gardeners' Chronicle* continue Professor Count Solm's story of the Tulip in Europe, and deal more especially with the so-called Tulip mania of the seventeenth century.

FRUIT GROWING.

EXPERIMENTS in fruit-growing have been in progress at the Agricultural Station of Laramie, Wyoming, since 1892, under the direction of Mr. B. C. Buffun, M.S., and the results which have now been published demonstrate to those who are looking for homes in the far West the fact, that Wyoming has horticultural possibilities of her own; and we think the facts may, further, be useful to fruit-growers in the old world.

The soils of the State are, as a rule, quite rich in the inorganic plant-foods, principally lacking in humus or vegetable mould, which supplies nitrogen. It is found advantageous to supply fruit, more especially orchard fruit, with some fertiliser rich in potash. Wood-ashes, when they can be obtained, answer the purpose well. Farmyard manure has proved a perfect fertiliser, and is used abundantly.

In deciding upon the location of an orchard, which is always an important step, it is stated that a north slope is preferable, because the snow stays longer in winter, and the buds are not apt to start too early in the spring. A well-drained soil is strongly recommended, because fruits should not be made to take up more water than they actually need. The amount of water required depends on the character and slope of the soil and subsoil, the condition of the weather, the kind of tree, whether in bearing or not, and the season.

In some orchards fruit trees are so disgracefully pruned, that a word of protest is added. In amputating the limbs of a man, it may be wise to take it off as far from the trunk as possible, but in pruning fruit-trees always pursue exactly the opposite policy. Many make a practice of cutting off limbs 2 or 3 inches from the trunk or main branches, which makes stubs that die and leave behind a diseased place or ugly scar. Whenever a branch or limb is removed, it should be cut off as close to the trunk or branch upon which it grows as possible, making a smooth cut, over which the bark will grow and hide the wound.

---

* *Weizen und Tulpe und deren Geschichte*, von H. Grafen zu Solms-Laubach, Professor der Botanik an der Universität, Strasburg. (Leipzig: Verlag von Arthur Felix, 1899.)

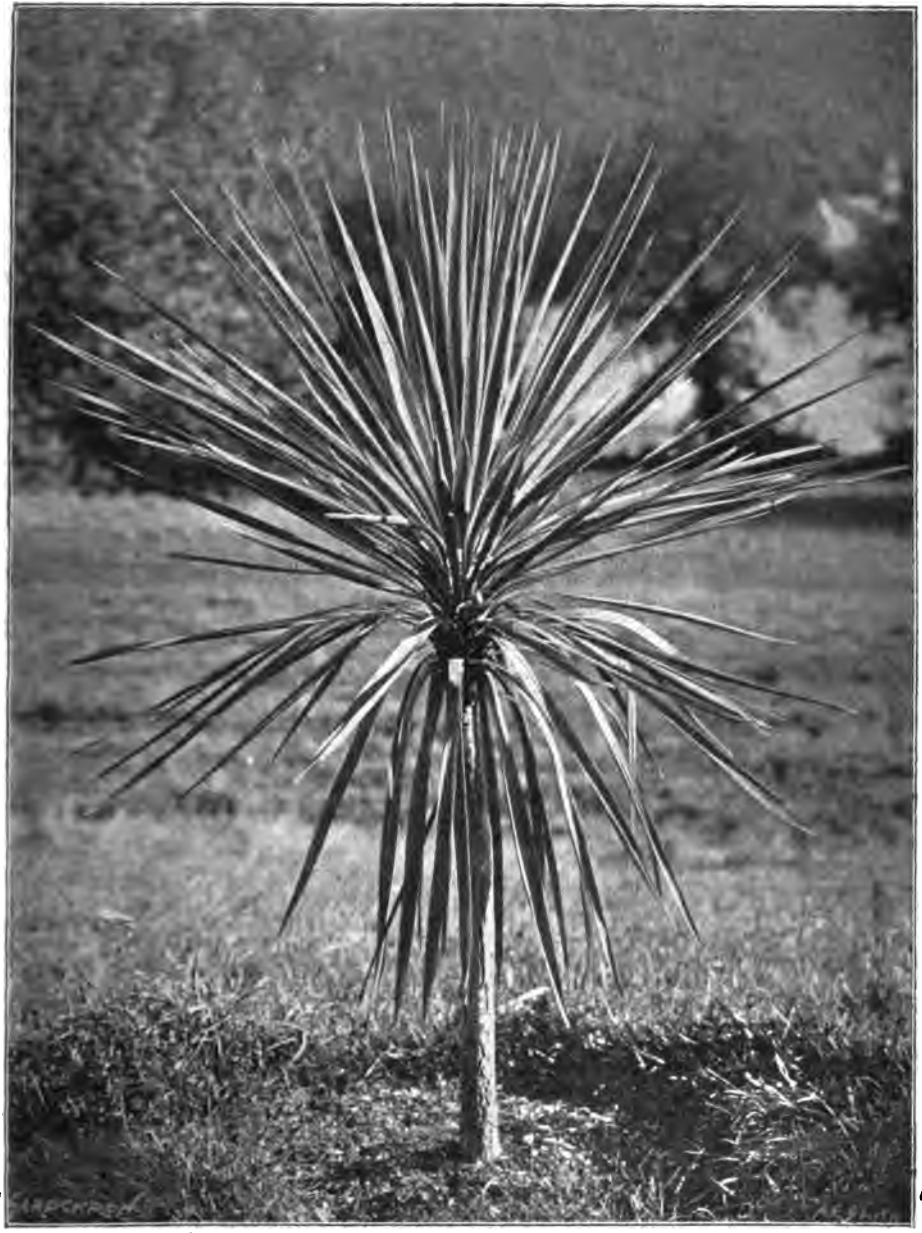


Fig. 106.—Dracæna Doucetti foliis variegatis.

In cutting-back the tops of trees, the method preferred is to make slanting cuts with a sharp knife or axe, rather than sawing the limb squarely off. In cutting-back top branches, cut off just above a bud or branch, so that there will be little or not any of the branch left which will die below the cut. Any serious pruning of the Apple should be done in the spring, before the buds swell. Cherries and Plums should be pruned in the summer, for if they are cut at other seasons, gum exudes from the wounds.

Summer pruning should never be severe, but should consist in rubbing-off buds which are developing where they are not wanted, and pinching-back slender shoots to increase fruitfulness, and make a well-formed tree.

Give orchards clean cultivation, never allow weeds to grow, and give the surface of the soil a shallow cultivation often. It is not recommended to grow any kind of Grass in the orchard. If crops are raised on the land between young trees, they should be planted some distance from them, and should consist of some hoed crop, which require shallow culture, and does not grow tall enough to shade the trees.

Rows of Currants and Gooseberries may be planted between the Apple-rows, but such fruits as Raspberries are not so good, as they grow tall, and require digging for their winter cultivation, that the roots of the trees are apt to be injured.

Raspberries succeeded remarkably well in this State, and the following results are quoted: Red varieties gave an average yield of 1400 quarts per acre. Yellow varieties gave an average yield of 920 quarts per acre. Blackcaps gave an average yield of 830 quarts per acre. The yields computed for the two seasons 1895 and 1896 give an average for all varieties grown of 953 quarts per acre. The market price was 25 cents per quart, giving an average value of 238·25 dollars. The cost of raising a crop of Raspberries is estimated at 18 dollars. This, with the total expense of picking and marketing the berries would make the cost 65·65 dollars, which leaves a net profit per acre of 172·60 dollars, equal to £35 19*s.* 2*d.* per acre.

Strawberries grown in 1896, in thirty-one varieties, gave an average yield of 6920 quarts per acre. The prices ranged from 10 to 15 cents per quart. Taking the lowest price, all varieties, good, bad, and indifferent, would have an average value of 692 dols. per acre. The estimated cost of raising an acre of Strawberries is put down at 93 dols. It is thought this would set out a new acre of the very best plants every year, allowing 4 dols. per thousand for the plants. Three cents per quart would be a liberal estimate of the cost of picking, boxing, crating, and hauling to market; or a total of 208·60 dols. per acre. The total cost, including picking, setting out new beds each year, &c., would be 301·60 dols. This leaves a net profit per acre of 390·40 dols., equal to £81 6*s.* 8*d.* per acre.

The largest yield of Strawberries per acre in 1896 was with the variety "Jucunda Improved," which gave 11,645 quarts; the second-best was "Pride of Berries," which yielded 11,220 quarts per acre; and the third-best was "Edgar Queen," which produced 10,285 quarts per acre.

These experiments indicate the success which may attend the careful fruit-grower, and the importance of the fruit industry in that country. *J. J. Willis, Harpenden.*

DRACÆNA DOUCETTI FOLIIS VARIEGATIS (Fig. 106).

This handsome variegated-leaved Dracæna has now stood out in front of my house without my protection whatever for nearly four years, having been planted out in the summer of 1895, after the severe and destructive frost of January 4, 5, of that year, which, had it been exposed to it, would doubtless have killed it to the ground at all events, as it did a fine 15-feet-high specimen of D. australis, which however has shot up again with great vigour, and has already attained to more than half its former height. The amount of frost experienced here was 29° for one night, 27° and 25° for the two following, and then a complete and rapid thaw. *W. E. Gumbleton.*

CHISWICK.

Time was when this much-honoured garden was difficult of access, but that drawback exists no longer, rail and tram afford frequent and rapid conveyance, and the gates of the gardens are always open in proper hours to visitors. They preserve to Chiswick an invaluable open space.

An inspection of the Chiswick Gardens shows great promise for the coming season, and many trials of interest are being carried out, which will be of interest not only to ourselves but to the numerous foreign "raisers," who, it is hoped, will visit us this summer on the occasion of the Hybridisation Conference. At the outset it may be stated that the condition of the grounds is excellent. Here and there is a section of a border waiting tillage and replanting, but such spots are few. The visitor cannot but feel that the Council in appointing Mr. S. T. Wright as the superintendent of the gardens to carry on the work so well performed for so long a period by Mr. A. F. Barron, made a happy choice.

Leaving the Council chamber, and going to the right, to the northern wall, there is to be noticed a rare trial of Violas, six strong plants of each variety appearing in each row, the trial reaching the whole length of the border, all the leading varieties being included in it. The cordon Peach and Nectarine trees on the wall on the left-hand show a thin crop owing to the action of the keen frost at the end of March, though the trees were protected by a double covering of netting. Then, turning southwards by the eastern boundary, Mr. Wright points out that the border by the wall is to be employed for a thorough trial of French Beans. The cordon fruit-trees on the wall are generally full of blossom. On the right hand, in addition to the old plantation of bush Apple-trees, a new one has been planted, and as a means of quick identification, the varieties are arranged alphabetically, running from east to west. This occupies the site of what was formerly a thicket of Plum-trees.

What was formerly a plantation of old Apple-trees, is now devoted to Strawberries and trials of vegetables, and adjoining this and reaching nearly to the great vinery, is a plantation of Plum-trees also alphabetically arranged. An inspection of the large vinery shows that the rods are making vigorous growth; and here it may be said that, in common with the vinery, the Pear-trees on the west side of the main dividing-line of wall promise unusual fertility, being full of blossom.

The rockwork at the west-end of the vinery is shortly to be remodelled and replanted; the collection of Primulaceæ, presented by Sir John Llewelyn, Bart., have not succeeded well, and will be transferred to pots. The broad border on the right of the walk, leading westward from the vinery, is to be planted with Cactus and Pompon Dahlias, which will form an interesting and valuable trial. In some of the beds on either side of the walk are some new species and varieties of Tulips, sent by Messrs. J. Veitch & Sons.

Southward there is a large trial of Peas, also of newer varieties of Potatos, Sweet Peas, and there is a large batch of Mr. Martin Smith's Carnations, looking remarkably well and growing vigorously. It should be said that on the north side of the large vinery there in an important trial of spring-sown Onions. There are also Cauliflowers in frames ready to be put out in the open.

The pits are full of interesting plants, and among them some hybrids sent by the Rev. C. Wolley-Dod, for the proximate conference. In the propagating-house is a trial-selection of Caladiums. In the Tomato-house is a large collection of plants in pots commencing to make a vigorous growth. The old vinery, in which the plants are of considerable age, promises exceedingly well, and so do the other houses devoted to Grape culture. The house of Figs looks capital; there is an abundant promise of fruit on every hand, and in the Peach-house the planted trees and those trained against the back wall are rich in promise.

This is but a hasty sketch of what may be regarded as the programme for the season at Chiswick. Given favourable weather, high development may be looked for, and the Fellows of the Society, if they will but pay a visit to the Society's gardens during the summer will find much to interest and instruct. *Wanderer.*

THE HARDY FLOWER GARDEN.

THE MUSCARI.

AMONG the most troublesome of all tasks to which a gardener can set himself, is that of verifying the nomenclature of certain plants. The more one works among these, the more necessary does it appear that some one would take them in hand and give us, not only careful scientific descriptions, such as appear in the *Gardeners' Chronicle*, but also faithfully coloured illustrations. In some genera verbal descriptions, however careful and precise, are not enough to meet our difficulties, nor can the dried plants in herbaria fully show the minute distinctions needed in some cases. Those who have ever tried to solve the puzzles presented by the Muscaris or Grape Hyacinths will agree with the writer in thinking that few genera present more difficulties. Could we but have a series of monographs, such as that of the Lilies, by Mr. H. J. Elwes; that of the Croci, by Mr. George Maw; or the forthcoming one on the Narcissi, by Mr. F. W. Burbidge, we should have less difficulty. Unfortunately, the writers who possess the combination of talents necessary for such work are exceedingly few, and it must be admitted that those who would seek to possess these monographs would be small in number, and would be still further reduced by the unavoidable cost of production of such works. In writing then of the Muscaris, it will, I hope, be accepted as a necessary proviso that I do not profess to say with authority that all of the Grape Hyacinths named are without dubiety so far as regards their nomenclature. The difficulty has been much increased by the impossibility of keeping a collection separate. They seed so freely, that in the course of a short time they are almost hopelessly intermingled, and could only be separated by one who thought of little else but Muscaris, and whose knowledge of the genus was more precise than most mortals can ever acquire.

Some few years ago, I made a collection of all the Muscaris I could obtain. They were planted side by side, and now the confusion is complete; and the only way to deal with them, is to remove them while in bloom with as much regard as possible to the necessity of putting the right tally to the right plant.

One cannot but advance strongly the proposition that the Muscaris are not enough grown. Their beauty is great. Even at the risk of quoting familiar words, one can hardly refrain from giving Ruskin's graphic and picturesque reference to the flower in the lecture on "Athene in the Earth," which is to be found in *The Queen of the Air*. He says:—"The Grape Hyacinth, which is, in South France, as if a cluster of Grapes and a hive of honey had been distilled and compressed together into one small boss of celled and beaded blue." As we look upon the flowers now in bloom amid the grass, in the borders, and in the rock-garden, we think how well our great English writer has depicted their beauties. Those of us who take delight in such things are not content with the flowers of "celled and beaded blue," but none the less do we admire them, although we seek to grow the varieties given us by the operation of Nature's laws. These are of other colours or of other shades than those of which Ruskin spoke, but we may yet say that no flowers are more beautiful than those whose colouring and form met with the approval of his artist eye. The others have their beauties too, and we see them with pleasure, whatever the colour of their flowers. Black-blue, cobalt-blue, azure-blue, pearl-blue, pure white, flesh-white or pink; all are alike lovely to those to whom flowers give joy. Some may have some reservation in saying as much of the Musk Hyacinth or M. comosum, both of which appeal, perhaps, to our other feelings more, but even these possess much of interest.

Before I proceed to say something about the species and varieties which I have seen or grown, it may not be unprofitable to say a little about their cultivation, although, under this heading there is not much room for discussion. Nearly all the cultivated plants give little trouble, and the exceptions may be treated of with but small detail.

Generally of small stature, the Muscaris do best in the front row of the border, in rockwork, or in grass. In any of these positions they will grow with but little preference for any particular soil, yet they seem to do best where it is of a light nature. In grass they are very pleasing, and a mass of the conical racemes of M. botryoides, with the green carpet given by the grass, looks exquisitely beautiful in April and early May. Most of the species increase rapidly by offsets or by seeds; so quickly, indeed, do some increase in certain gardens that they are looked upon as weeds —but weeds of beauty worth retaining.

One exception in many gardens to the ease of cultivation which applies to the greater number of the species is M. moschatum, which in such places generally flowers the first season, but not in succeeding years. It appears to require a hot position, and thorough ripening in summer. M. comosum is easily grown in light soil. *S. Arnott.*

(*To be continued.*)

SOUTH AFRICAN NOTES.

JOHANNESBURG.

(*Continued from page* 276.)

To many people the word Johannesburg conveys the idea of a huge ugly mining camp, set down in the middle of a vast treeless plain. The reality is quite different. Climb up the rocky hill above Doornfontein suburb and survey the great forest at your feet of deepest blue-green Eucalyptus and Pinus insignis, interspersed with miles of roads lined with handsome villas, each with a charming garden screened from the public gaze by neatly-trimmed hedges of Cupressus macrocarpa. Beyond are the towers and domes of the great town, and further off are the mines—huge heaps of white sand, the rock from which the gold has been extracted, tall, black iron smoke-stacks, and confused masses of galvanised iron buildings, from whence comes the never-ceasing roar of the stamping batteries, like breakers on an iron-bound coast.

Let us descend and enter one of the miniature Edens we have just caught a glimpse of. Passing the garden-gate, we are in a sheltered spot, where wind and dust can hardly penetrate; hence many plants thrive here which are failures in more exposed situations. Next the hedge is a broad border edged with Violets and gay with Cactus Dahlias, new Cannas, Tea Roses, and herbaceous Phloxes. In the background is a very healthy Cedrus Deodara, 20 feet high; a fine Juniperus bermudiana, and a Cupressus Lawsoniana in perfect health. A Pinus canariensis is noted, but this fine Conifer must have shelter to do well; near by is a large Laurustinus, and a Benthamia fragifera, laden with fruit. On the well-kept lawn in front of the house are a few Camellias, bristling with buds, and a hybrid Rhododendron, not very happy. The main walk is bordered with large plants of Azalea indica in tubs, which bloom well in the spring. On the cool, shaded south side of the house is a border filled with Hydrangeas, Fuchsias, and Pelargoniums, a Tree Fern, and a couple of Musa Ensete. The porch is festooned with Rose Reine Marie Henriette and Celine Forestier, and the verandah adorned with hanging baskets of blue Lobelia and very large rambling plants of Mandevilla suaveolens and Wistaria sinensis. On one side of the house rocky steps lead up to a well-kept croquet-lawn; a trellis-work on one side is a mass of Ivy-leaf Pelargonium in full bloom. A small orchard at the back is planted with Peaches, Apricots, and Apples, all of which bear well.

Such is one of the many well-kept gardens one sees; but in the middle of town are a great many ugly iron shanties, with not a scrap of garden-ground or anything green in view. It was to give pleasure to the unfortunate people living in such streets that my main object was to make this park as attractive as possible. True, I have had many failures, but then such is always the case. "The workman hath in his heart a purpose; he carrieth in mind the whole form which his work should have; there wanteth not in him skill and desire to bring his labour to the best effect; only the matter which he hath to work on is unframeable." Hooker's *Polity*, quoted in a note to Cary's *Dante*, Par. Canto I.

Owing to our very dry winter and spring, all plants which flower early in the year do not thrive very well here—such as Tulips, Hyacinths, Daffodils, Narcissus, Anemones, Ranunculus, Snowdrops, Cyclamen, and most Cape bulbs (they have a moist winter and spring at the Cape). Yet Englishmen delight to have some flowers in their gardens to remind them of their far-off homes, so Violets, Primroses, and Daisies, are general favourites, and often do very well; so also do Columbines and Pansies. Honesty I have tried to grow in vain! When the rains fairly set in from Midsummer to autumn, then Roses and Carnations give plenty of bloom, and make a very good show. Later on, annuals give satisfaction, together with Cannas, Tuberoses, Heliotrope, Pentstemons, Pampas Grass, Phloxes, Campanulas, and Chrysanthemums. The only flowers which can be relied on through the winter in the open are, Phlox Drummondi, Candytuft, Indian Pink, and Mignonette.

There is a considerable demand for cut flowers and Ferns of all classes; we have morning sales of cut flowers and pot plants in the market, and nearly half a dozen florists shops in town. During the summer, all demands are supplied from local nurseries, but in winter the Cape and Natal sends us Roses, Azaleas, Callas, Heaths, and Proteas, for as yet no one has gone in for forcing fruits, vegetables, or flowers under glass. The vegetable market is very well supplied all the year round; and the growers are mostly local Italians and Portuguese.

Of fruit and fruit-trees and tree planting, I have something still to say before bringing these rambling notes to a close. *R. W. Adlam, Joubert Park, Johannesburg, Transvaal.*

(*To be continued.*)

CULTURAL MEMORANDA.

THE PROPAGATION OF VIOLETS.

In reply to Mr. F. Strong's criticism in the *Gardeners' Chronicle*, p. 268, I may say that I wrote my note as a reminder to those who, from lack of the necessary convenience for earlier propagation, or from choice, use the strong side-growths which are found upon plants that have flowered in the winter in cold pits or frames. When the old plants have been properly attended to during the winter there is little difficulty in obtaining healthy runners with roots attached, and if such are planted and afforded the necessary attention they form good plants by the autumn. *C. R. Fielder.*

AGAPANTHUS UMBELLATUS.

This plant in warm localities is so far hardy as to withstand ordinary winters, if afforded some slight protection; but the practice is not to be recommended, high winds damaging the leaves, and making the plant very unsightly. The old plants should be occasionally divided, or repotted, using loamy soil as a basis, dried cow-manure, sand, and bone-meal, doing the potting with some degree of firmness. In the growing season they require much water and full sunshine.

Repotting should not be performed frequently, but the size of the specimens and their condition will afford the gardener indications in this matter When large plants become pot-bound, they derive benefit from being turned out and divided, and on no account should a richer soil be used than that indicated, or flowers will be but sparsely produced. Division should be carried out during March or April, and the plants placed in a forcing-house and be daily syringed, and after a few days hardened off, in readiness for placing out of doors.

The Agapanthus is semi-aquatic, and the best position for it is near a basin, a lake, or a stream, as much water is required; indeed, the plant may be deluged with it in its season of growth. During the winter, just sufficient water should be afforded as will prevent loss of the leaves; and the fuller the rest, the better the results in the matter of flowers. As soon as frost approaches, the plants should be taken indoors, where frost can be excluded. *H. T. M.*

ALOCASIAS.

The noble proportions and handsomely-marked foliage of these plants should commend them to all lovers of ornamental-leaved stove plants. Within recent years several magnificent varieties have been introduced to our gardens, and the genus has become thereby more popular than was the case at one time. All the species, with the exception of A. macrorhiza variegata, require stove treatment throughout the year. During the growing season, which extends from March to October, the plants require a temperature of 70°, with a rise to 85°, accompanied with abundance of humidity. A temperature of 65° in the winter will suffice, and the supply of water, both overhead and at the roots, at this period must be considerably reduced; still, these plants should not be dried off, but be kept gently growing.

The variety A. macrorhiza variegata, when well grown is admirably adapted for greenhouse or conservatory decoration, but it is now seldom met with, owing probably to the tendency of the leaf-colour to degenerate. A well-grown specimen of this variety should have its large light-green leaves heavily blotched with white. To succeed in maintaining this characteristic a too-liberal treatment should be avoided during the early stages of growth. The end of the month of February is a good time for repotting those specimens that require it, and young plants may be repotted at any time when it is necessary. A light open soil is essential, viz., one consisting of three-fifths fibrous peat broken up by hand, and two-fifths chopped sphagnum-moss, little bits of charcoal, and sharp silver-sand. The pots or deep pans in which the plants are grown should be clean and well drained, i.e., the potsherds should be well placed, for much water is needed by the plants. The pots or pans should be half filled with drainage, and over this a thick layer of the roughest of the compost should be placed. Having thus prepared a pot, carefully remove some of the exhausted soil, and place the plant on the new material, the crown of the root-stock coming somewhat higher than the rim of the pot; then fill in with soil, finishing it off in a convex form, or the thick fleshy stems will be apt to decay.

When the repotting is finished, place the plants in the warmest part of the stove, and supply them with tepid water, so as to wet every part. The after-treatment will consist of frequent syringings with clean rain-water, and damping the paths and stages twice or thrice daily. Clear soot-water afforded at alternate waterings does good. Thrips and red-spider sometimes appear on the plants, but these are easily eradicated by sponging the leaves with tepid-water in which a bit of soft-soap is dissolved; indeed, the plants are much benefited by an occasional sponging of the leaves. Propagation is effected by dividing the crowns at the repotting. A few of the most desirable species are A. metallica, A. intermedia, A. Jenningsii, A. Martin Cahuzac, A. Lowi, A. argyrea, A. zebrina, A. Sanderiana, A. Veitchi, A. Mortfontainensis. *H. T. M., Stoneleigh.*

CLEMATIS FLAMMULA.

This is, perhaps, one of the oldest Clematis in cultivation, and it is of use in covering trellis-work, the stumps of trees, &c.; the flowers are not showy, but they have a most delicious fragrance, and they are produced in huge masses. The plant is readily increased from cuttings taken off with a heel, and put in sandy soil under a hand-light. The roots of this variety are frequently used for grafting the more beautiful varieties upon. Many years ago, when I was employed in Fisher, Holmes & Sibray's nursery at Sheffield, the roots were simply slit down and the wedge-shaped scions inserted, tied, and then potted and plunged in a warm propagating-house; and, if my memory serves me aright, they never had any losses among the grafts. *H. Markham, Wrotham Park.*

THE ROSARY.

NEW ROSES, &c.

With regard to the new Roses which are being brought out, there is no diminution in their numbers, for I find that the foreign raisers announce forty-four Teas, fifteen hybrid Teas, and fifteen hybrid Perpetuals; it will be seen that this list varies considerably from what we used to have when the Hybrid Perpetuals comprised the great bulk. It does not at all follow that we shall have the opportunity of seeing many of these, indeed the experience of the last few years points to the contrary; but it is different in regard to our home-raised Roses, which the Waltham Cross, Cheshunt, and Newtownards firms have brought forward. There is no doubt we shall have the opportunity of seeing these, and some interest will be excited by the Gold Medal Roses which have been thus honoured by the National Rose Society.

There is another point which rosarians will do well to bear in mind this year; the National Rose Society will publish a new catalogue in the autumn, and its members are particulárly requested to notice the new varieties which will be exhibited, in order to see which are to be placed in the new catalogue, and also what Roses at present there are to be expurgated, for, while many varieties still retain their place in the favour of the Rose-grower, there are others which have to give place to newer ones of the same colour, which possess some superiority. There are, it is true, some varieties that are less likely to be excelled, such as General Jacqueminot, which has been in cultivation forty-six years, and others of our home-raised Roses, like Beauty of Waltham, thirty-seven years. What a multitude of flowers have come and gone during that long period! The National Rose Society will not hold a southern exhibition this year, and therefore there will not be such an opportunity of seeing garden Roses as there has been during the last two or three years, for the date of the Crystal Palace shuts out a good many of the early flowers in this section. Most of the seedling Roses are past, and if we are to see them anywhere it will most probably be at the Royal Horticultural Society's show, at the Drill Hall. No doubt there will be garden Roses at the Palace, and probably some of our northern amateurs may be able to show them in numbers. *Wild Rose.*

TREES AND SHRUBS.

SORBUS AUCUPARIA, L., S DULCIS LACINIATA, BEISSNER.

In the number of *Die Gartenwelt* for March 5 last, Mr. L. Beissner, one of the first German dendrologists, describes the above new variety of our common Mountain Ash, and a coloured plate very well illustrates the beauty of this novelty. The variety, it is said, is a natural sport of S. Aucuparia var. dulcis (moravica). In 1893, Mr. Ordenny, head gardener of the Prince of Lobkowitz, at Eisenberg, near Borix (Bohemia), discovered the mother plant in the highest regions of the (Bohemia) Orc mountains.

Mr. Beissner describes the plant as follows:—Branches and stalks of leaves bright dark blood-red; leaves thin and regularly laciniate, like fronds of Ferns, of a deep lustrous green in summer, golden-yellow in autumn; lowest leaves of totally different form, curled; the ripe fruits are tile-coloured, edible like those of S. Ancuparia moravica, in taste resembling those of our common red Bilberry (Vaccinium vitis) when preserved.

This new sport of S. Aucuparia is as hardy as the typical plant, and if planted where it has a dark background, will produce a very beautiful effect. *C. K. S.*

THE HERBACEOUS BORDER.

THE BEDDING VIOLA OF THE FUTURE.

There is still need for a race of early flowering Violas. Of the many hundreds of seedlings which are raised annually, and of the numerous varieties sent out every year, nothing that I have seen can lay claim to special precocity. Beds of Hyacinths and Tulips especially, have a dreary appearance until the beginning of April, when the plants begin to develop their flower-stems. But if we had a race of Violas that would come into bloom with the Crocus and the Primrose, they would be of great value, especially in our London parks. Large patches of grass are in full glow of vernal beauty; Crocus, Scilla, Chionodoxa, Narcissus, Tulip, &c., vie with each other in cheerful floral service. But the flower beds are yet dreary, except where there is a margin of early spring flowering bulbs. Even Myosotis dissitiflora, except in highly favourable spots, is not yet in flower.

That the Viola can be "educated" into precocity, there can be no doubt, just as the late Mr. William Ingram of Belvoir "educated," as he happily termed it, his Wallflowers, Anemones, and other spring flowers into the habit of early blooming.

The mistake made by some raisers of new varieties is that they think its highest service is on the exhibition table. Its real service is in the flower garden, and especially in early spring. That is a matter, there is reason to fear, too much overlooked by those who raise seedlings. Habit of growth has been made subordinate to the shape and size of the blossoms. The Viola of the future should be early flowering, because an early variety can also be employed in the summer display; but no resource can make a Viola that flowers naturally in May to bloom in March. An earlier bloom could be obtained in the open by taking cuttings in July, placing them in a cold frame, which would bring the young plants into bloom earlier than if wintered entirely in the open, and planting out as soon as in flower.

It is a ridiculous designation to term the present day Violas, as some do, "tufted Pansies." Too many of the newer varieties are by no means of close tufted growth; they are, instead, lanky, and can be employed with effect in the flower garden in association with other plants which furnish a kind of support. What is wanted is a really tufted growth, dwarf and compact, with the flowers produced in symmetrical masses well above the leaves. Varieties which throw their flowers at irregular heights are not effective in the flower-garden. Persistency in bloom is another point, the property of lasting in flower for a considerable time; so long as Violas produce seeds freely, so long will there be loss of bloom. Freedom and continuity of bloom, and sterility in seed-bearing, should characterise the Violas of the future. Then endurance is required, meaning thereby the property of enduring hot sunshine and drying weather. The heat and drought of last summer brought out the peculiar weakness of many varieties which flower through one half of May and June, and then go down under the heat of July. Further, the newer Violas should be as far as possible mildew-proof. Some take the mildew speedily, and soon terminate their floral services; those that endure are but few. The rayless and miniature varieties appear to be constitutionally weak, and unable to stand our southern hot summers. It is possible that the efforts made to withdraw from the flowers anything in the way of coloured ray-lines round the eye has led to breeding to a great extent in-and-in, with resultant weakness of constitution.

There is ample room for an improved race of Violas. Early flowering, persistent, and constitutionally vigorous, a race is wanted which, if planted out in October, will be in bloom at the end of March; and with the assistance of an occasional top-dressing, continue in bloom till September. There must be so much of constitutional vigour as to resist such attacks as mildew; and so much of sterility as will conduce to a continuous, well-sustained bloom. He who can produce such a race will be a benefactor to floriculture. *Florist.*

VARIORUM.

The Broccoli Traffic in Cornwall.—In the early part of the season the Broccoli crops looked anything but promising. But things took a turn for the better, and the toothsome vegetable not merely came on fast, but in very fine condition. On one day in the second week in April, there were dispatched from the stations of Penzance, Marazion, St. Erth, and St. Ives, 223 truck loads. It was the record day of the season, and the largest quantity of Broccoli ever sent in one day from West Cornwall. Taking the quantity loaded and dispatched on that day to average two and a half tons to the truck, it gives a total of 557½ tons. The crates usually average thirteen to the ton, so that the total number of crates would be 7,427; and carrying the calculation a little further, and estimating the crates to contain five dozen heads of Broccoli each, which is a fair average, we have a total of 434,820 Broccoli. *The West Briton.*

FOREIGN CORRESPONDENCE.

LANDSCAPE GARDENING IN CALIFORNIA.

Liberality is a prominent trait of the American, as has recently been illustrated in California. The International competition for the best scheme for a State University, in Berkeley, is hardly over, and is yet fresh in everybody's memory. Mrs. Phœbe Hearst supplied the means which made such an undertaking possible; and the eleven landscape architects, fortunate enough to win prizes in the preliminary competition, visited us to study the grounds, and compose new designs for the final competition to be held in September; this year not in Antwerp as hitherto, but in San Francisco, our metropolis. After the adoption of the final plan, a prize of 8000 dols. will be awarded to the successful designer. The grounds comprise some 250 acres, and are to be widened to about 300, to include the grand piles of rockery, will be designed and laid out to correspond with the noble work of structural architecture. The slope, at the foot of which these buildings will be erected, is grand in shape and outline. It faces south-west, lies opposite the Golden Gate, the entrance to the spacious Bay of San Francisco, and rises from 200 to 550 feet in elevation, having Mount Grizzly at its back, and surmounting it. Small groves of old Oaks (Quercus agrifolia) grow along the banks of the creeks across the site, and clumps of Eucalyptus that can be turned to account when remodelling the landscape.

Mrs. Hearst's generosity goes even further than this. The idea has been conceived that the streets of San Francisco should be improved, and in response to the invitation of the above-named lady, the architects here examined the city also, and are to lay before us suggestions and plans for the improvement of a site as grand as that upon which Rome was built, and as charming as is the country around Naples.

Some of the leading ladies of the city have established the "California Club," and their self-imposed duty is to add everything possible to the beautifying and improvement of the surroundings of the town. Playgrounds for children are to be opened, beginning with the providing of gymnastic and other apparatus on vacant spaces, the laying-out of race-tracks for the boys of the town, and the arrangement of sand-heaps for the youngsters to play in. Most of our public squares create an impression that the gardeners who laid them out learned their profession from practising the making of sand-heaps and mud-pies. Slowly but surely we are awakening from such conditions, and the grand charter, formed from ideas incorporated from those of the best municipal governments here and abroad, and adopted now for our metropolis, will come into force next January. The requirements of the Civil Service will rule in all departments, and gardening in our squares will be free from disturbing political "pulls." It is the ladies of the "California Club" also who have taken up the idea of laying-out our squares effectively. It is proposed to furnish the most central one entirely with shrubs and trees from our own forests. And should we not be proud of our flora, and feel ashamed of having neglected to profit by its charms for so long? Our nurserymen have given up growing Californian shrubs, because nothing but Palms and Bananas would suit the gardeners and their clients. It would be well if, for some years to come, some pest, even worse than the San José scale, would devour every stiff-leaved, varnished-looking Palm grown by us. Monterey Cypress, Austrian Pine, and Eucalyptus trees, form the mass of the plantations in our parks, and only gradually are these being replaced by plants that should have been grown under their shade for ten or fifteen years past.

And as we try to improve on a small scale in our towns, we are also realising the need of greater care of our forests and preserves. One tract after another has been set aside from entry by settlers, and we are bound to secure the yet remaining plantations of timber along the main water-sheds. A new society has been formed for this very purpose, and it has met with the hearty co-operation of every club working on similar or affiliated lines. Future visitors to our State will find signs of a new era, and will give us credit for undertaking an important enterprise before it is too late to perfect it. *Geo. Hansen.*

RUXLEY LODGE.

Lord Foley is making a considerable addition to the glass structures in the gardens at Ruxley Lodge, his residence near Esher. During the past two or three years he has built a moderate-sized Cherry or orchard-house, with two divisions, and a case or two to enclose some fine specimen Fig-trees, that used to fruit well upon a protected wall, but not with equal certainty to those inside. An old Rose-house has been removed, and a fine and lofty structure with a lantern-roof has just been completed upon the same site. But these are quite minor additions and alterations compared with the large conservatory now in course of erection.

The residence will be extended on the west side by an elevated passage, which will connect with a tower, now being built, at a distance of 120 feet from the house. This tower will be upwards of 80 feet high, and will command extensive views of the Surrey and Sussex landscapes. The wall from the house to the tower will be something like 20 feet high, and upon reaching the tower will make an elbow for a further distance of 55 feet. The conservatory will follow this wall, and the length of the structure will therefore be about 174 feet, 119 feet of which will have an aspect nearly due south, and 55 feet will face the east. Its height is to be about 30 feet, the back of the roof resting on the above-mentioned wall. The width of the conservatory will be 26 feet throughout. This house will be very much the largest in these gardens, and will afford plenty of space for standard Orange-trees, Palms, Tree-Ferns, Myrtles, Eugenias, Araucarias, Camellias, Azaleas, &c., many of which will doubtless be planted in borders, where growth is more free than in the case of cultivation in pots or tubs.

Lord Foley enlarged the dwelling-house a couple of years or so back, by building a billiard-room and library; and previous to this considerable building had been done to render the accommodation of the stables more complete.

It has been a matter of much inconvenience at Ruxley that there exists a public footpath through the park, which passes the south front of the dwelling at such a distance that pedestrians were in full view from the flower-garden and the sitting-rooms. Last autumn efforts were made to lessen the inconvenience by throwing the soil into two terraces, which now moderately well screen the footway, and when the Yew-trees that have been planted upon these banks have grown up, the screen will be an effective one. Several acres of land have been added to the pleasure-grounds, and new walks are in course of formation, that will approach a mile in length.

The Fruit Prospects

at Ruxley are at present very satisfactory. The Vines, without exception, are showing good crops, and the earliest Grapes are now colouring. The trees in the earliest Peach-house, like many in the suburbs of London, have not more than a thin crop, but those in the succession-houses and late ones will need to be thinned severely. Figs, always a specialty at Ruxley, have been in use for dessert since the end of February; and Melons will soon be ripe. As in numerous other gardens, the variety Royal Sovereign is now the favourite Strawberry for forcing, and some plants now fruiting in pots are carrying an unusually heavy crop of fruits of first-class quality.

Out-of-door fruits of a tender nature have been greatly affected by the weather, but there will probably be a thin crop of Apricots upon walls; and of Peaches also upon walls, there will be it is hoped, as good a crop as usual. The out-of-door Peach-crop rarely fails at Ruxley. Strawberry-plants give abundant promise. Apples and Pears will hardly be safe until the end of the present month, but the wood was thoroughly ripened last autumn, and there is an abundance of blossom, now at its best.

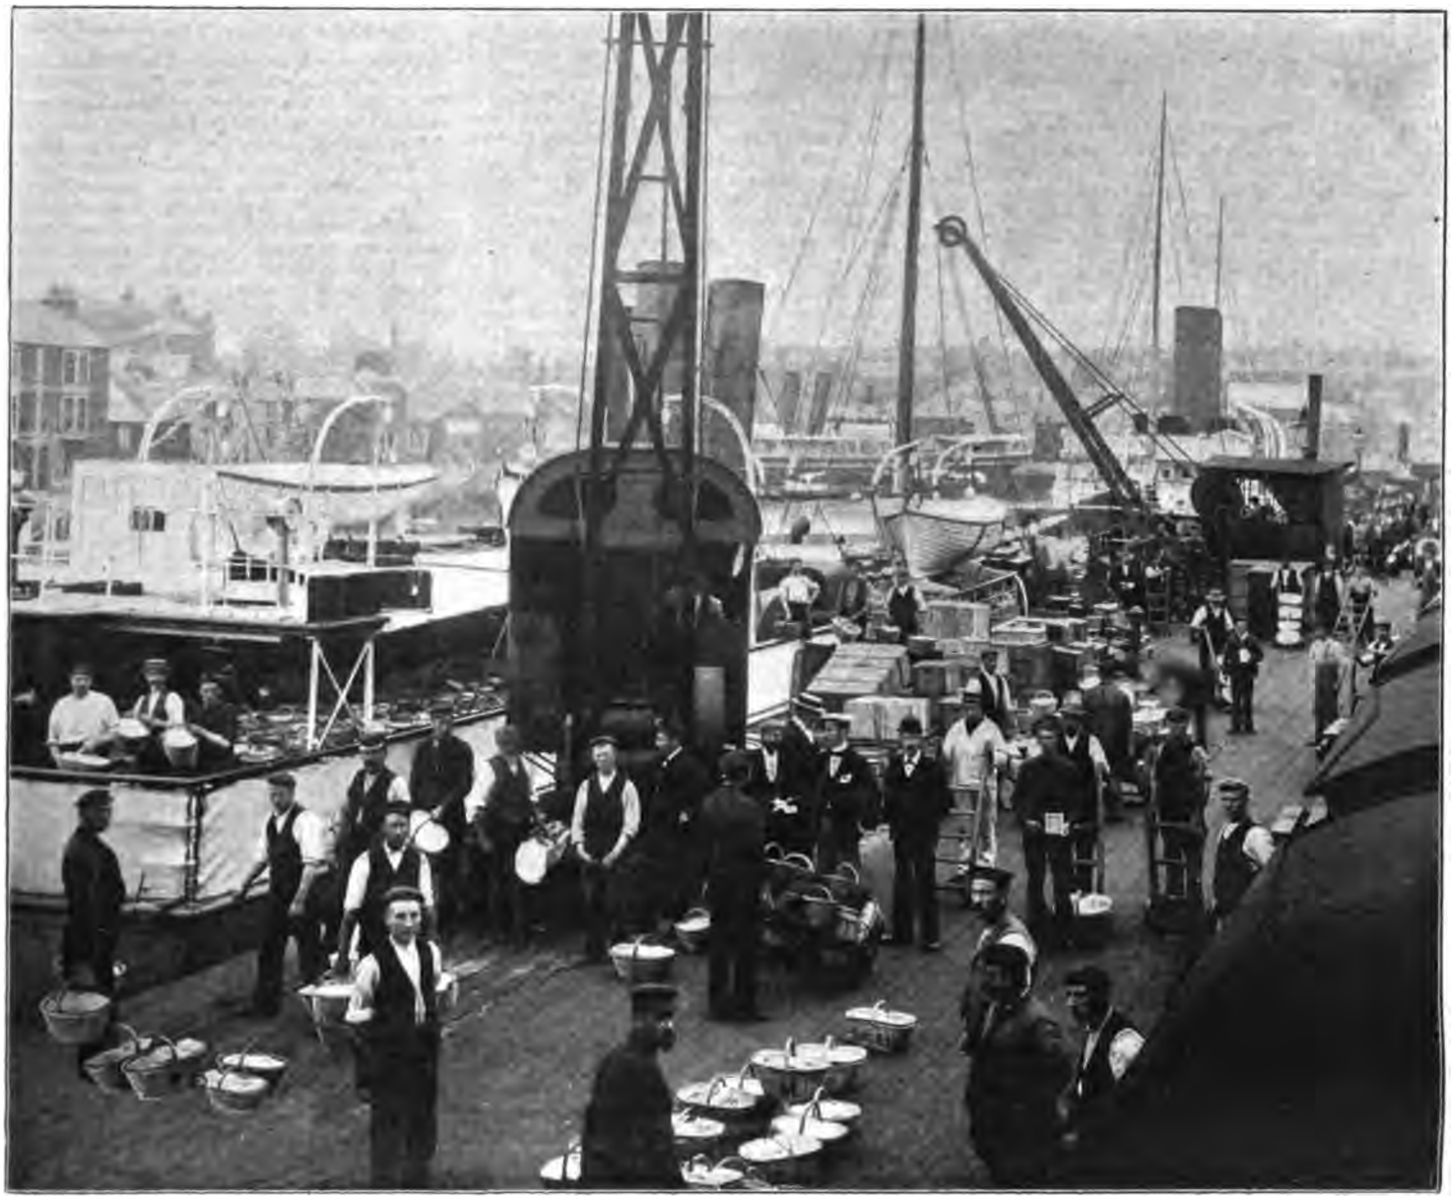

FIG. 107.—MARKET GARDENING IN THE CHANNEL ISLANDS: ARRIVAL OF THE GREAT WESTERN S.S. "LYNX" AT WEYMOUTH.

Lord Foley takes a very close interest in the management of the gardens, but his veteran gardener, Mr. J. W. Miller, now in his seventy-eighth year, nevertheless finds abundant room for his extraordinary activity of mind and body.

MARKET GARDENING IN THE CHANNEL ISLANDS.

IN supplement to the series of articles from our "Special Correspondent," describing the very extensive horticultural trade now existing in the Islands of Jersey and Guernsey, we now reproduce a photograph of one of the steamers by which the produce is conveyed to the mainland for distribution in the markets. For this purpose, and for the conveyance of passengers, the steamships of the London & South-Western Railway Company from Southampton, and those of the Great Western Railway Company from Weymouth are continually plying across the Channel. The accompanying illustration from a photograph (fig. 107) represents the ss. *Lynx*, one of the Great Western Railway Company's boats, as she appeared immediately after her arrival at Weymouth one day last autumn. The vessel bore very large quantities of Grapes, Tomatos, and other produce in cross-handled baskets, all securely packed and labelled. No sooner had she been secured to the wharf, than a number of men commenced to unload the horticultural cargo, passing the baskets from one to the other, and depositing them in a position, where all were sorted according to the marks upon them.

Following this, they were immediately placed upon some trucks waiting on a siding close at hand, for despatch to the various markets. The cargo on this particular day was addressed to about sixty different markets, chiefly those of the Midland and Northern shires.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By W. STRUGNELL, Gardener to the Right Hon. W. H. LONG, Rood Ashton, Trowbridge.

The Second Early Vinery.—The thinning of the bunches must be done betimes, as this operation can be carried out more easily when the berries are small, and the danger of piercing them with the point of the scissors is less. They grow very freely in size after the thinning. Never over-crop a Vine, or a lessening of the vigour of the plant, bringing in its train insect troubles, small berries, and indifferent colour, will surely result. This is a point difficult to give advice about, so much depending on particular circumstances as to what constitutes a light, medium, or full crop. As soon as the berries are thinned a plentiful application of water should be made to the border, and if a suitable liquid manure is not obtainable, artificial manures may be employed with about equal benefit. [A manure for the Vine should contain nitrate of potash, 1 cwt.; sulphate of lime, 1 cwt.; and dissolved bones, 2 cwt., and this manure may be applied at the rate of 2 lb. per superficial square yard, at intervals of four weeks (*vide* Barron on *Vines and Vine-culture*). Ed.] The damping of the vinery-floor and the path in the evening with liquid manure, stimulates growth, and aids in keeping red-spider in check. The lateral shoots must be stopped once in seven days, and plenty of space afforded for the primary leaves to expand without crowding, as well as sufficient space between them and the glass to prevent any scalding.

Early Melons.—The earliest crop of these fruits being in a more or less forward state, and the top and bottom heat of the right degree, it will be an easy matter to have ripe fruits in the present month. In order to ensure high flavour, the common practice of drying off the plants by withholding water from the soil should be avoided. The chief object the gardener has in view in drying off his Melon-plants is the prevention of cracking. However, if the plants are regularly afforded water, the degree of moisture in the soil is not allowed to fluctuate in the fruits less prone to splitting. For example, if a heavy application of water be applied to a dry soil, and the Melons are almost or quite fully grown, some or all of them will split. When in the last stages of ripening, each fruit should be examined daily, and upon the slightest sign of separation of the stem from the fruit, that fruit should be cut together with the stalk and placed in a cool room, or if required for immediate consumption, on a shelf in a warm house is the better place. Melons vary much in their ripening, some varieties developing flavour, and the rind softening whilst still on the plant; others require to be for several days in a cool room before perfect condition is attained. Careful ventilating of the Melon-house is of much importance, for if the air be moisture-laden, a similar effect is produced as that which follows an application of water to the roots.

General Treatment.—More seeds of Melons in variety may now be sown, one or two seeds in a pot. The fruits from this sowing will ripen during the months of July and August. The best kind of soil to employ in the pots is turfy-loam, in which some mortar-rubble, finely sifted, is mixed. Melons from this sowing may be grown in unheated pits and frames, provided a bottom-heat of about 80° is afforded by a bed of tree-leaves and stable-litter. These plants may be grown in any sufficiently warm house, close to the glass, until such time as they are strong enough for planting in the pits, &c. The soil of the beds should always be allowed to get warm throughout before planting is done. Earlier-sown plants should not be allowed to get pot-bound before transferring them either to larger pots or to the beds. The stopping and regulating of the growth of Melons need almost daily attention in heated pits, and when the flowers show, afford air as freely as may be safe, having regard to the nature of the weather, fertilising freshly opened flowers about mid-day, and when they are perfectly dry. Syringing during this stage should not be practised. When it is seen that three or four fruits per plant are increasing in size rapidly, all superfluous growth should be suppressed. When the roots are observed to have reached the surface of the hillocks on which the plants stand, apply a thin layer of warmed loam, repeating this dressing as occasion may require, till the bed is brought up to one level surface, but always keeping that part of it where the stems are, higher than the rest of the bed. In the case of loam of poor quality having to be employed, liquid-manure may occasionally be used, after the fruit has begun to swell; or even manure in small quantity mixed with the soil previous to planting. When an ordinary hotbed of manure, &c., supplies the warmth, it is well to cover the bed with boards or slates, so as to keep the roots out of these materials. The number of plants in a pit or frame will depend on the size of the lights, but the largest seldom need more than two per hillock, and for small lights, i.e., 5 by 4 feet, one is sufficient. In all cases the seedlings must have the point pinched out after the first pair of true leaves have formed, thus obtaining three to four shoots, each of which may be allowed to carry one fruit.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Cattleya Warscewiczii, commonly known as C. gigas, is now making rapid growth, but until the bulbs have almost attained their full length, few roots are made. A very prolonged rest is required by the various forms of this species, and even when any plant commences to grow anew, only sufficient water need be afforded to prevent the pseudo-bulbs shrivelling. When the sheaths appear rather more may be applied, carefully guarding against excess, especially in conjunction with a moist atmosphere. Do not afford a top-dressing until the sheaths have appeared. C. gigas should be repotted only when new roots appear at the base, even should it be during the flowering season. That the plants appreciate light is proved by the fact that those suspended nearest to the roof-glass produce the greatest number of flowers. Suspended plants become dry soon after watering, and they are generally in conditions more resembling those of their natural habitat.

On Exhibiting Orchids.—At this season, a large number of choice Orchids are usually taken from their quarters and conveyed by road or rail to exhibitions, which more often than not are held under canvas. That the plants so exhibited suffer, goes without saying, considering the difference in the conditions obtaining in their home quarters, and those inseparable from the exhibition-tent. One would hardly suppose that Cattleyas and Lælias suffer to a much greater extent than other Orchids from this cause, but the suffering is increased if the plants have been afforded water before leaving the garden. This fact being understood, plants selected for exhibition should have no water afforded for a day or two previously, unless they are in absolute need of it, and then a slight sprinkling of the surface will suffice. The latter method should also be adopted during an exhibition that lasts two or three days, and also on the plants returning home, which kind of treatment, if accompanied by an extra amount of shading for a few days, will enable the plants to recover from their journey. Another source of harm consists in thrusting stakes into the mass of roots, sphagnum-moss, &c, often to the injury of many of the roots. With small plants this may be avoided by enveloping the pot in wood-wool, and thrusting the stakes into that. Large plants usually have stakes fixed in the pots at the time of repotting, and these can often be made to support a plant by splicing other sticks to them when packing them; but where there is none, those required should be fixed very carefully.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Cleaning the Land.—In sunny weather let the hoe be kept steadily at work in order to aërate the soil and kill the weeds, this work being chiefly carried out with the Dutch-hoe, let it be used pretty constantly amongst growing crops. The Onion crop should be taken in hand at an early date, and if the plants are doing well, thin out some of the plants when they are 2 inches high, but the final thinning may come later on. Some gardeners sow new Onion seed somewhat thinly, and do not thin the plants. The produce is varied in size, and therefore economical in use. A dressing of soot will be found useful for Onions where the maggot is feared. Whatever the crop, thinning should not be deferred till crowding takes place.

Mushrooms.—Beds may still be made up at intervals in size and number to suit the demand, and now that the weather is warmer, some beds may be made in a cool shed, or in a sheltered spot in the open; the principal point to be observed being good stable-manure from corn-fed horses, which should be sweetened by repeated turning. It needs not to consist entirely of the dung of horses, but a little short straw as well may be used. Let the beds be made bit by bit, packing the materials by treading and beating them, as the work proceeds. Spawning should not take place till the warmth of a bed has sunk to 98°, and after that is done the beds may be cased over without further delay; all beds, whether in the open or in the Mushroom-house, should be repeatedly examined, and if found dry, they should be afforded warm water, first removing the covering, if any. The temperature of a Mushroom-house should not be more than 60° or less than 58°.

Seed Beds.—Let a careful examination be made of all seed-beds, making good all mishaps without delay. The weather so far has been unfavourable to the germination of seeds and the growth of seedlings, so that should mild showery weather set in, plants raised from seed sown at this date will in some instances catch up those sown earlier. The young Brussel Sprouts, Cauliflowers, Savoys, &c., raised from seed sown in March having made little progress, should be afforded water, following this with a slight dusting of fresh soot and lime.

Turnips.—A considerable breadth of land may now be sown with two or three varieties; those who prefer the yellow-fleshed Turnips sowing Golden Ball or Orange Lily, two good-flavoured varieties. Excellent white Turnips for present sowings are Snowball, Early Milan, and White Stone. Keep a sharp outlook for the Turnip-flea; dress the rows frequently with wood-ashes, soot, and lime, and should the pest become very troublesome apply water frequently, and then sprinkle wood-ashes over the plants. The chief aim should be the encouragement of growth in the plants, as it is only in the seed-leaf stage that the flea is so injurious.

Cucumbers for Pickling.—Seed should be sown three in a 60-pot, and the pots placed in a mild hot-bed or a forcing-pit, putting out the plants on ridges under hand-lights when they are large enough, and have been hardened off a little. A warmth of 55° to 65° is ample, and such will keep the plants sturdy and healthy till the time arrives to set them out.

FORESTRY.

By A. C. Forbes.

Shedding of Scots Firs Needles.—The danger of leaving brushwood to rot in a plantation, is, in many cases, more imaginary than real, for it is very seldom that insect or fungoid-attack on living trees is occasioned by insects or fungi, which rather infest dead twigs and small branches. The chief danger occurs during the short period between the cutting of the wood and that stage of decay at which the food material of these parasites has lost its sustaining properties, for the reproductive powers of these pests is so great, that want of food or a suitable medium for growth, seems their only limit. Large quantities of partially dead shoots, in the presence of a parasitic fungus, may thus become a source of danger to living trees above and around it, for the air at times, being full of its spores, any weak place in leaf or shoot is at once seized upon, and becomes a centre of infection to neighbouring parts. An instance of fungus-attack recently came under my notice, which illustrated this point very clearly. In September, 1897, the rides in a young plantation of mixed Conifers (in which Scots Fir predominated), were widened for shooting purposes, and the cut trees dragged back under the cover of the trees which stood behind them. This was done partly to save trouble of burning or removing, and partly to provide ground-cover for rabbits, and no further notice was taken of them. In February of this year the Scotch Fir on the margin of the rides began to put on a scorched appearance, as if a fire had been lit too near them, and had singed the needles. Inspection proved, however, that this was due to the attack of a fungus, which is too well known amongst young Scots Fir plantations in Northern Europe, but which does not as a rule give much trouble in this country, although the fungus is found more or less on Scots Fir everywhere. Known to mycologists as Hysterium pinaster, it attacks the needles of the Scots Fir generally, although its effect is more easily seen on plants from one to ten years of age. The first external symptom of the disease is a discoloration of the needles, brown and purple patches taking the place of the green of healthy leaves. Examined under the microscope at this stage, yellowish-brown masses of mycelium will be found in the fibro-vascular bundle of the needle, and in the spaces between the resin-ducts. In a week or two the inner surface of the needle begins to shrink, leaving the sharp edges projecting, these latter ultimately curling round as the shrivelling process goes on. In April and May the affected needles usually fall off, leaving the shoot almost bare until the new shoot is developed in June. In the following autumn or spring, according to the weather, numerous black specks appear on the dead needles, the spermogonia and apothecia of the fungus, and by which its spores are produced. According to R. Hartig, a spell of wet weather is necessary for the bursting of the apothecia and the escape of the spores from the asci, and warm wet winters are very favourable to the spread of the disease. Occasionally the fructifications appear before the fall of the needle, and this occurred in the present attack. This disease is so widely spread, and so disastrous to seed beds of Scots Fir in many of the German forests, that great difficulty is frequently experienced in regenerating cleared ground, and the term "schütte" popularly given to it on account of its effect on the needles, indicates the reputation it has so long held as a parasitic pest. Under the circumstances usually prevalent in the raising of plantations in this country, the spread of the disease from one wood to the other is less likely to occur, than in a compact area of Scots Fir forest where young and old plantations adjoin. After the trees have obtained a height of a few feet it does not appear to give much trouble so far as their growth is concerned, but the case quoted above proves that favourable circumstances for its development may render it troublesome to older plantations. The one in question is ten years of age, and growing on good loamy soil, too good, in fact, for Scots Fir. The whole of the widened rides have their marginal trees affected in the same way, independent of exposure or aspect, although it is quite possible that sudden exposure to light and sun, after growing in partial shade, may have injured the affected needles to some extent, and predisposed them to attack. A few yards further into the cover the trees are not similarly affected, although the fungus occurs on the needles of suppressed and weakly branches. At the present time (end of April) many trees are quite bare of needles, even up to the leading shoot, and many others are totally brown, so that at least six weeks must elapse before the trees resume their normal appearance. Although appearances point to the conclusion that the dead and decaying trees left in the plantation after cutting, had a good deal to do with the attack, it is possible that it is merely a coincidence, and that spores from the suppressed branches might have effected the same result had the cut trees been made away with at the time. It is evident, however, that it is unsafe to neglect the simplest precautions in the presence of these minute foes of trees or plants, and that cleanliness in a plantation may be as necessary as in other matters of daily life.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Seedling Carnations.—If seeds were sown as directed in a previous calendar, the young plants will now require to be put singly into small pots, and subsequently removed to a cool pit or frame. Keep the atmosphere somewhat close for a few days, and shade the plants during bright sunshine until the roots have again become active, when quite opposite conditions will need to be gradually introduced.

Celosias and Cockscombs are best kept in small pots until they show signs of flowering, when they may be potted into 5-inch pots. For this purpose use a rich open compost, such as three parts loam and one part each of spent hot-bed manure and leaf-soil, adding plenty of sand. The plants should be kept near to the roof-glass in a night temperature of about 60°, and of 70° by day. Syringe freely and often among the pots as a preventive of attacks from red-spider. When the flowers are well developed, the plants may be gradually hardened, and removed to the conservatory or greenhouse.

Acalypha hispida (Sanderi).—Keep a sharp outlook for aphis in the flower racemes. They are difficult of detection until the portion of the raceme attacked has become discoloured. It would be well to occasionally place these Acalyphas in a house about to be fumigated. The lower leaves of the plants are liable to be attacked by red-spider, but, as the surface of the leaves is smooth, sponging with soft-soap and water is an effective means by which to clean them.

Show Pelargoniums.—In giving specimen plants the final tying, the shoots should be so disposed that the flower-trusses will be equally distributed over the plant. Examine the plants for aphis, and if its presence be detected, fumigate them with Richards's XL-All Insecticide. The flowering will be greatly assisted by affording the plants an occasional application of weak manure-water.

Miscellaneous.—Prick out seedlings of Primula obconica, P. floribunda, P. verticillata, &c., directly they are large enough to be handled, and keep them well shaded for a time. Seedlings of Tuberous Begonias and Gloxinias may be potted in small pots. Sow seeds of Primula chinensis and Cinerarias for early winter flowering.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore Maidenhead.

Sweet Cherries.—The growth of these trees, owing to north-east winds and general low temperature, has been considerably checked, and as a result the black aphis has already begun to infest the foliage. This pest should be forthwith destroyed with Quassia or Tobacco-water, or by fumigation under cloths, the remedies being repeatedly applied so long as any insects are observed. The curled-up leaves form a hiding-place for caterpillars, which should be killed by squeezing the leaves between the finger and thumb, and grubs should be similarly treated. Owing to the backwardness of the trees, syringing with strong mixtures has hitherto been unadvisable, but now that the fruit is set and swelling, the means above-named will not be injurious. In mild weather the trees may also be syringed with clear water, which will help in the same way. The frosts have considerably thinned the crops of sweet Cherries, and a full one will be an exception in this district.

Morello Cherry-trees are as yet scarcely in bloom, and they give promise of an abundance of blossom, which at this date may reasonably be expected to be safe from frost, although the weather still remains cold and unseasonable. Where the soil of the borders of Morello Cherry-trees is heavy and retentive, a few inches of the upper crust may be removed, substituting soil for it with which a good proportion of mortar rubbish and small brick-rubble has been mixed. In lack of a suitable sort of soil, a good dressing of mortar rubbish alone may be pointed into the surface.

General Remarks.—Peaches, Apricots, Plums, and Cherries may now have their protective coverings removed, as the foliage now acts as a protection against any frost that we are likely to have, in the south at the least. If the copings are portable they may remain over the trees for another week or two as a slight extra protection. Netting or other materials used should be thoroughly dried and then be put into store. Where grafting has been carried on, the clay coverings of the grafts will, after the dry weather of the past week or two, require to be smeared over with wet hands, or thin slip of clay-and-water, in order to fill up the cracks. It is imperative that moisture and air be excluded as much as possible from the bark of both scion and stock, otherwise no union will result. Strawberry-plants grown solely for furnishing runners should have the flower-trusses removed.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Herbaceous Borders.—The Dutch-hoe should be used frequently. Thin out all weak growths from plants of Aconitum, Delphinium, Aster (perennial), Phlox, &c. Any that have made growths 1 foot to 18 inches high should be staked, and if the clumps be large, drive three stakes 1 inch in thickness at angles around the plant. These should be of sufficient height. Divide the shoots equally, and loop them loosely together with tarred-string in such a way that the plant can grow freely. Thin out annuals which have been sown in the flower borders, allowing each plant sufficient space for its natural development.

Pentstemons.—Autumn-struck cuttings should be planted out in well-drained soil; and if this be poor, some leaf-mould and sand may be added. Pinch the points of the shoots of any that have a leggy habit. Plants raised from seed are more robust, and require more space.

Stocks.—The dwarf German, large-flowered, or the Giant Ten-Week that have been raised from seeds, may now be planted in good rich soil, either in groups or beds, selecting for them a cool and moist position. The smallest plants should be selected as they usually produce the best double flowers. Those of strong growth, with forked roots, are invariably single-flowered varieties. Stocks should never be allowed to become dry at the roots. Afford them liquid-manure when the spikes are formed and it will increase the size and colour of the flowers.

Tuberous-rooted Begonias.—Many of the seedlings that have been pricked out in boxes or pans will now be sufficiently large to be potted off into 4-inch pots. Well drain these pots, and add a little more loam to the compost than was recommended for them when being transferred from the seed-bed Afford the plants but little water until the root have again become active, but a slight damping between the pots will be helpful. Admit as much light as possible, but shade from the sun, and prepare the plants for transference to the beds by the middle of June.

Megaseas, also known as Giant Saxifrages, are effective the whole year through. They are easy of cultivation in good stiff loam, and if clumps be parted and planted at this season, they will start quickly into growth. The bright green leaves in the summer, and the lovely tints these become in the autumn, alone make them worthy of prominent positions in the dressed grounds. M. crassifolia and M. cordifolia (purpurea are beautiful early-flowering sorts that require some protection from frost. M. Milesii is very pretty, but being delicate requires wintering in a cold frame. What are known as the Newry hybrids are very robust, and in these gardens flower much later than others. The varieties Brilliant, Distinction, corrugata, Sturdy, and Progress, planted in bold masses on the margin of the lake here, and in conspicuous places in the pleasure-grounds, attract much attention from visitors. Saxifraga peltata, both in exposed and shady parts of the garden, grows freely and produces large loose clusters of pale pink flowers and huge cup-shaped leaves. S. ciliata, another fine-leaved plant, is deciduous in winter, and requires a sheltered, partially-shaded nook, and well-drained soil.

THE APIARY.

By Expert.

Swarming and its Prevention.—Amid the many devices, good and bad, introduced of late years, in the shape of "non-swarming hives," "swarm-preventers," &c., the fullest credit must be given to those who have given time and thought in furtherance of the object of ensuring perfect control over the issue of undesirable swarms. Nor can there be any doubt that, with this end in view, several very good hives have been devised, and are now on the market. The principle involved, however, is nothing more than the well-known axiom of "giving timely room and ventilation;" and we quite believe that equally good results will be secured by those who do not care to invest in a non-swarming hive or appliance, by taking an equal amount of trouble (in the application of the timely room and ventilation principle) as is required in the working of a "non-swarmer." On the other hand, we consider the newest type of non-swarming hive to be advantageous, apart from the idea of swarm-preventing, in that the feature of getting bees to work down into a box of shallow frames placed below the brood-nest is an excellent one. It saves the time so frequently wasted by bees hanging idly outside the hive for days together for sheer want of room inside. Moreover, the subsequent removal of combs and bees—when the latter have got fairly to work—to a position above the brood-nest, does away with the frequent reluctance of bees to pass through the excluder, and enter surplus chambers.

Renewing Combs in Brood-chamber.—We strongly advise the removal, every spring, of a couple of outside combs—choosing the oldest or most faulty ones, of course—substituting frames fitted with full sheets of foundation. Then after the bees have fairly started to build out the foundation, the frame may be placed right in the centre of the brood-nest without the slightest fear of chilled brood. By this means we get two new combs built every season; and by gradually renewing the whole, not only keep the brood-combs in good condition, but avoid faulty ones, and thus conduce to the comfort of handling workable frames when manipulating our hives.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	MAY 13	Royal Botanic Society, Meeting.
TUESDAY,	MAY 16	Royal Horticultural Society's Committees. National Rose Society's Committee Meeting
WEDNESDAY,	MAY 17	Imperial Russian Gardeners' Association: International Exhibition at St. Petersburg (10 days).
FRIDAY,	MAY 19	Manchester Royal Botanical Society's Whitsuntide Exhibition, continuing until May 25. Royal Botanic Society, Lecture.

SALES.

TUESDAY,	MAY 16	Established Orchids, at Protheroe & Morris' Rooms. The Collection of Duplicate Orchids formed by F. Hardy, Esq., at Tyntesfield, Ashton-on-Mersey, by Protheroe & Morris (2 days).
WEDNESDAY,	MAY 17	Lilies, Gladioli, Carnations, Greenhouse Plants, Palm Seeds, &c., at Protheroe & Morris' Rooms. Unreserved Sale of Greenhouse and Bedding Plants, by order of Mr. Geo. Allin, at the Floral Hall, Highbury Place, N., by Mr. Herbert Wm. Rendell.
FRIDAY,	MAY 19	Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period April 30 to May 6, 1899. Height above sea-level 24 feet.

Remarks.—The weather has been rather dull, with cold winds, and very sharp frosts on the mornings on the 4th, 5th, and 6th inst. No rain has fallen since the 29th ult.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—54·8°.

ACTUAL TEMPERATURES:—

LONDON.—*May* 10 (12 P.M.): Max. 60°; Min. 45°.
PROVINCES.—*May* 10 (6 P.M.): Max. 62°, Bath; Min. 49°, Tynemouth.

A Horticultural Hall.

WE may shortly learn of some further practical attempt being made to arouse public interest in this object, as it is rumoured that the Council of the Royal Horticultural Society will shortly be urged to approach the Government with a view to obtain the grant of a suitable site for the erection of such a hall. No doubt, could such a site be obtained, an immense deal would be gained. It is not at all improbable that, with a site furnished, the money could be raised to enable the hall to be erected; but the getting of the site by purchase presents very great difficulty, as land is so costly in London, especially in any central position. Indeed, so enormous is the value of land that it would, were it a case of purchase, cost as much to purchase a site as to erect a suitable building. But it needs a good deal of confidence in the generosity of a Government to assume that it will grant what is proposed to be asked for. The present Government has, no doubt, been generous to the Royal Botanic Society in the matter of leasing to them that splendid area in the Regent's Park. It is scarcely too much to say that, either from a scientific point of view, or from that of a national industry, the Royal Horticultural Society accomplishes more in one year than the Royal Botanic Society has done in the whole term of its existence. What the Royal Agricultural Society is to agriculture the Royal Horticultural Society is to horticulture, if, indeed, it be not very much more. But Governments are hard to move, especially if any appeal to their generosity, even for most important national purposes, has not some powerful influences behind it, or if no political object is to be gained. No doubt a government may find itself justified in sheltering itself behind a refusal, on the ground that, granting so great a favour to one society would but entail similar applications from many other bodies. In this connection it may be urged that several scientific societies are already housed in one building by the favour of the Government. The Royal Society, the Chemical Society, the Linnean Society, the Society of Antiquaries, the Royal Academy, all find quarters in Burlington House; whilst the University of London occupies a site in immediate proximity, a site that may be vacated if the University should be transferred to the Imperial Institute.

A horticultural hall, if erected, could hardly be continuously employed for horticultural purposes, and as a huge area for exhibition, there is good reason to assume that such a building would be available for similar purposes by other, and to some extent, cognate bodies. For all ordinary purposes, even the Royal Horticultural Society could not well utilise a huge hall more frequently than once a fortnight, and as ample light is indispensable for most shows, and for garden products notably, the roof must be largely of glass. It is evident, therefore, that the basement would have to consist of a series of offices with a lofty, well lighted hall above. That several great scientific or industrial societies could thus be housed under one roof is evident.

It is pleaded that for the purposes of the Royal Horticultural Society's meetings, of which there are some twenty-four now held during the year, the present Drill Hall is not large enough. That is sometimes, but not always, true. Still, we may not forget that the securing of the Drill Hall when South Kensington was evacuated was a great gain, and the society has under its roof developed wonderfully. But it must also be remembered that for London the Drill Hall is a large building, and except Olympia, the Crystal and Alexandra Palaces, or the Agricultural Hall, it would be very difficult to find a building in the metropolis that would give more available space. If, therefore, the present Drill Hall be admitted to be occasionally too small, a very large site would be needful to enable such hall as seems desired to be provided. That could hardly be done in London; but, of course, it might be possible to secure a building, giving halls one above the other, and in that way providing the needful area. Still, that is not what the advocates for more room seem to desire. If the proposed appeal be made to the Government, there is just a possibility of success, whilst the chances of refusal are very much greater, in spite of the fact that the Royal Horticultural Society is probably the most important body of its kind in relation to horticulture in the whole world.

It has often been said that the Westminster Aquarium occupies one of the finest sites in the kingdom, yet it is but a music-hall on a large scale. True, its area is occasionally employed for exhibitions, but the surroundings render its utilisation for such meetings as those of the Royal Horticultural Society impossible. St. Stephen's Hall is at present not largely used. It is roomy, but needs a materially lighter roof. Its position is first rate, and had it the aid of a powerful light, and if it were anywhere else but where it is, it would make a capital hall for the purposes of the Royal Horticultural Society. At present it stands in a great position, and is unworthily occupied. Probably it is larger than the Drill Hall, but that is uncertain. If not larger, no gain would attach to removing to it. However, a pretty problem is proposed to be considered, but the solution is not to be readily found.

ROYAL HORTICULTURAL SOCIETY.—At the next meeting of the Committees of this Society to be held on Tuesday, May 16, a lecture on some of the plants exhibited will be given at 3 o'Clock, by the Rev. Prof. G. HENSLOW.

NATIONAL ROSE SOCIETY. — The Rev. H. HONYWOOD D'OMBRAIN and Mr. EDWARD MAWLEY, hon. secretaries, desire us to state that a meeting of the General Purposes Committee will be held at the Rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday, the 16th inst., at 3 P.M., for business purposes.

HORTICULTURAL CLUB.—The usual monthly dinner and conversazione will take place on Tuesday, May 16, at 6 P.M. The subject for discussion will be "The Method of Preserving Vegetables by Evaporation, as Carried Out at Rayne in Essex," to be opened by Mr. R. GOFTON SALMOND.

THE SURVEYORS' INSTITUTION.—The Institution will be closed from May 16 to May 25 (both inclusive) to facilitate the removal to the society's new house, 12, Great George Street, Westminster, to which all communications should be addressed on and after May 24.—The next ordinary general meeting will be held on Monday, May 15, 1899, when a paper will be read by Mr. R. M. D. SANDERS (Fellow), entitled "Land Purchase in Ireland." The chair will be taken at 8 o'clock.

THE HYBRIDISATION CONFERENCE.—Judging from what we hear, this is likely to be an important affair. Several of the leading experimentalists from the United States, as well as from the continent, have intimated their intention of being present, and others who are not able to come will

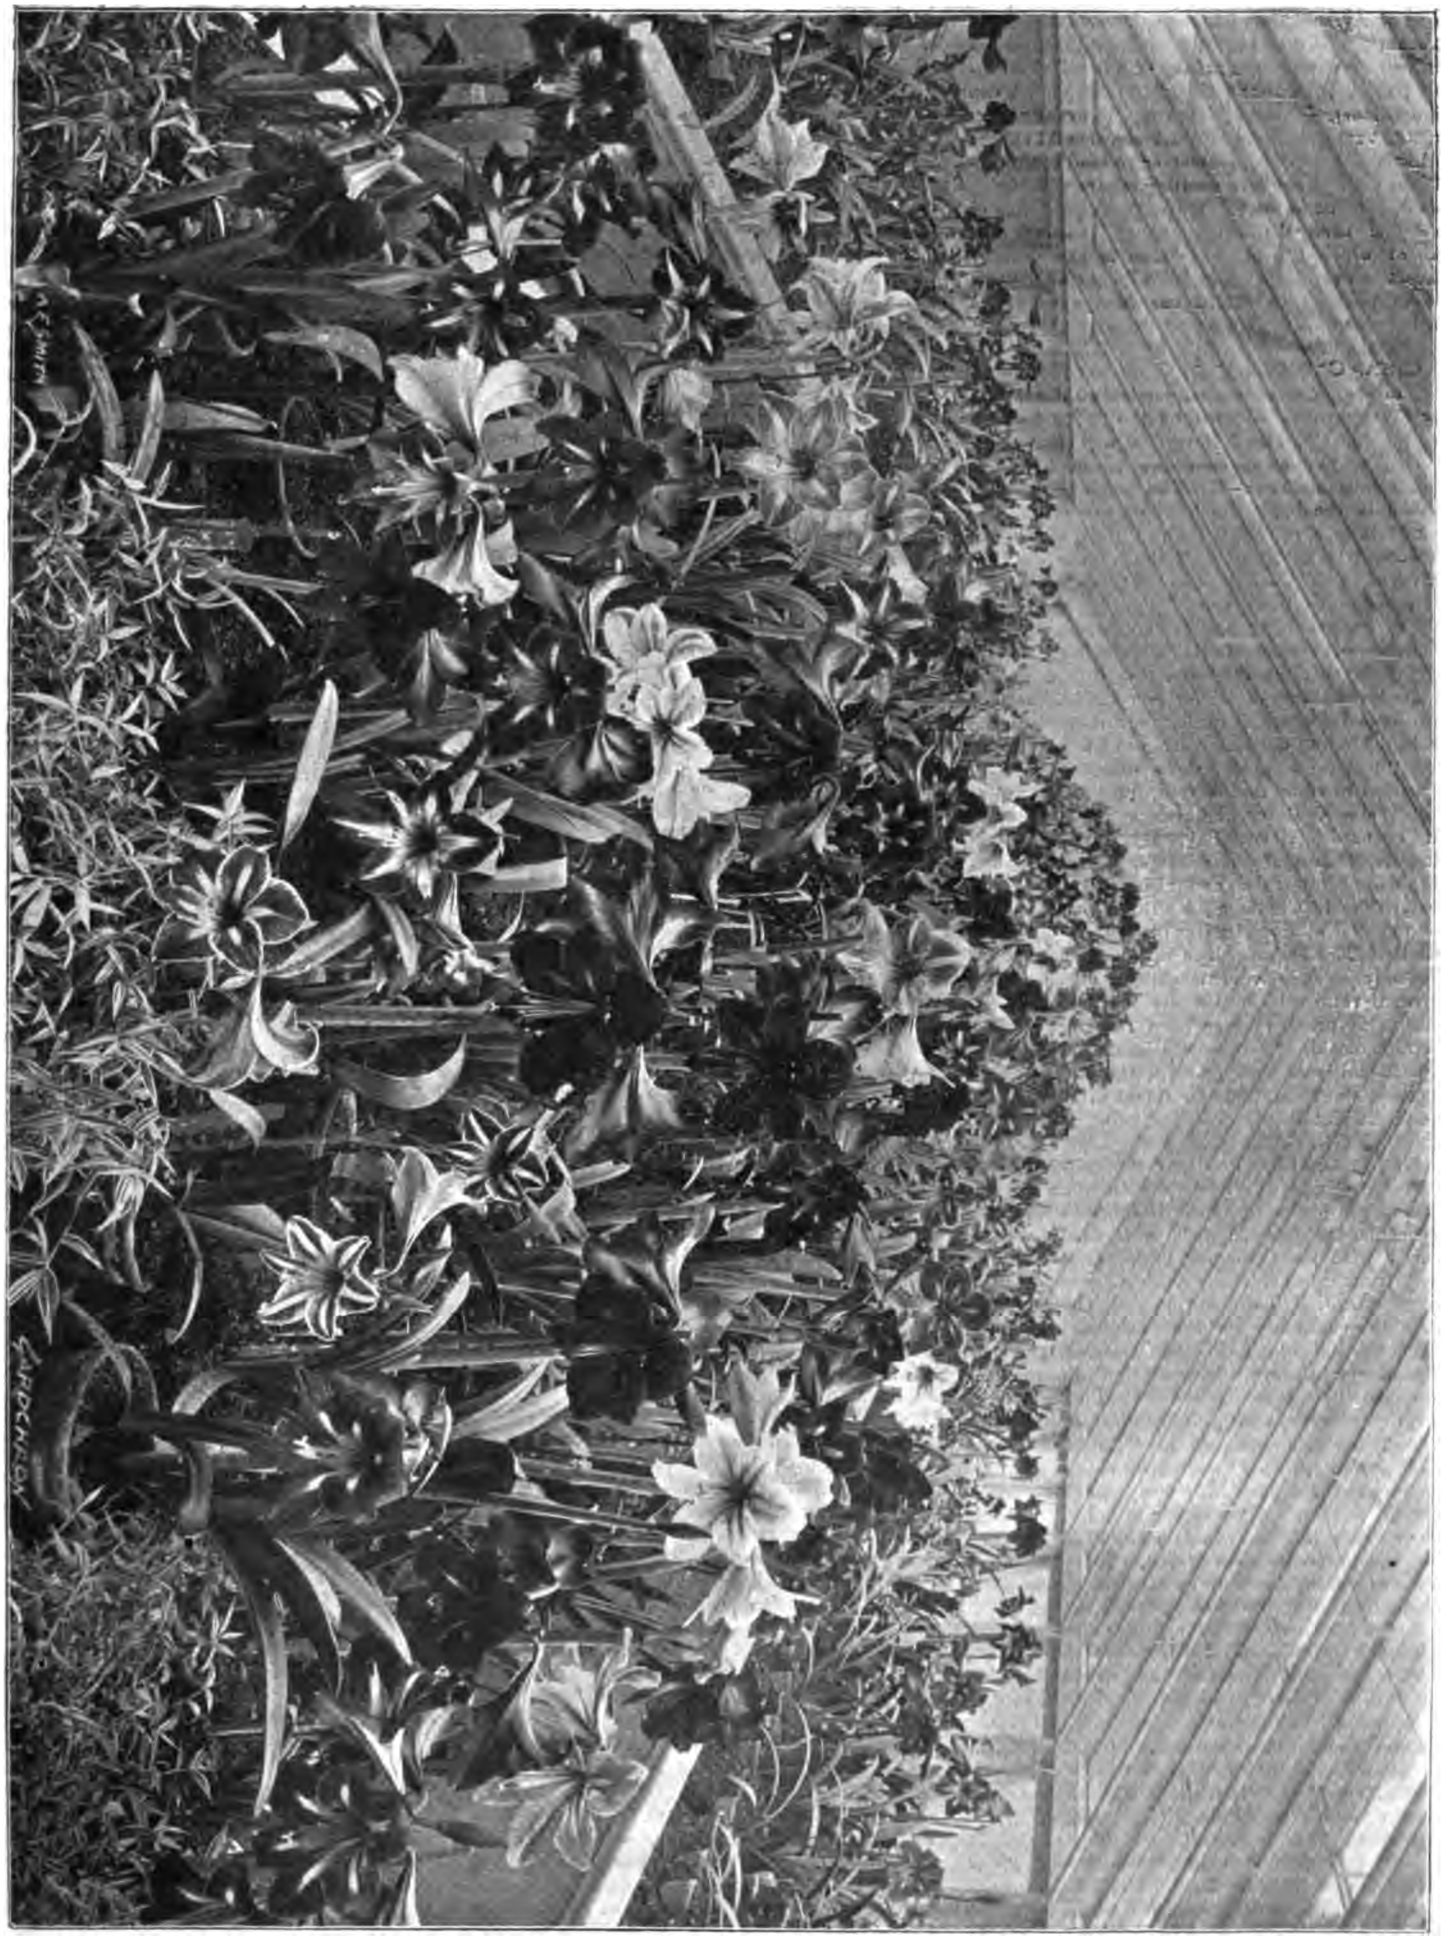

FIG. 108.—INTERIOR OF CAPTAIN HOLFORD'S HIPPEASTRUM-HOUSE, WESTONBIRT, TETBURY. (SEE P. 301.)

send papers or illustrative specimens. We hear of a representative from the United States Department of Agriculture, of Messrs. DE LA DEVANSAYE (Anthuriums), MEEHAN, Philadelphia; HUGO DE VRIES, Amsterdam; BAILEY, of Cornell University; FOCKE, BURBANK, MAX LEICHTLIN, DUVAL (Bromeliads), MARLIAC, MARON, TRUFFAUT, LEMOINE, VILMORIN, and of other continental raisers as likely either to be present or to send communications; whilst our own seedling-raisers will doubtless be present in force. We expect a gathering of scientific horticulturists and experimenters the like of which has not been seen in this country since the ever memorable "'66." Arrangements are in progress to accord our foreign visitors a cordial reception.

CHEAP CONVEYANCE OF COUNTRY PRODUCE.—Here are some additional particulars relating to the system to be adopted by the South Eastern and London, Chatham & Dover Railway Companies, of which we gave an announcement in our last issue. The conditions are:—(1) The produce shall be packed in the boxes which are on sale at the different stations, or similar ones; (2) the boxes shall be secured by nails only; (3) the produce shall be conveyed at owner's risk, and the carriage prepaid, the prepayment being made by parcels stamps on sale at the stations; and (4) no box shall be of greater weight than 60 lb. Provided that these conditions are fulfilled the produce will be conveyed at a reduced charge of 4*d.* for every 20 lb., and 1*d.* additional for every 5 lb., or part thereof, up to 60 lb. (including delivery within the usual limits), from all stations (except those within 20 miles of Charing Cross) to Birchington, Broadstairs, Deal and Walmer, Dover, Folkestone, Hastings and St. Leonards, Herne Bay, Hythe, Littlestone, Margate, Ramsgate, Sandgate, Westgate-on-Sea, and Whitstable, and also from all South-Eastern and Chatham & Dover stations to London and stations in the companies' suburban district. The boxes, which are intended for use once only, so as to avoid the expense of conveyance of small returned empties, are to be sold at the stations at prices ranging from 1½*d.* to 5*d.* The adoption of this system should be of great advantage to cultivators of fruit in the south-eastern counties, and to consumers resident in London and the places mentioned.

NATIONAL FOOTPATH ASSOCIATION. — A general meeting of this Society was held on Monday evening, the 8th inst., at the Holborn Restaurant, to consider the question of the amalgamation of the Society with the Commons Preservation Society. Lord RIBBLESDALE, the President, occupied the chair. Mr. J. F. TORR having read the report of the acting secretary on the business transacted during the last six months, the Chairman said, that when, six months ago, the secretary died, proposals were made by representatives of the Commons Preservation Society, which had the same interest as themselves, for the amalgamation of the two societies. A sub-committee which was appointed to consider the question had gone fully into the delicate question of financial adjustment, and had reported unanimously in favour of amalgamation. He moved that the proposals be accepted. The motion was seconded by Sir JOHN BRUNNER, M.P., and after discussion the proposal was agreed to.

HOLLY "GOLDEN KING." — We learn from Messrs. LITTLE & BALLANTYNE, Carlisle, that this new variety of Holly, which received an Award of Merit at the last Temple Show of the Royal Horticultural Society, has obtained a First-class Silver Medal at the Ghent show—a fact we were unable to ascertain at the time. It is a distinct variety, and the yellow variegation is very bright.

WINTER-FLOWERING TROPÆOLUM.—When at Cambridge recently we noticed in the University Botanic Gardens a very valuable winter-flowering Tropæolum, that furnished a rafter in one of the span-roofed houses there, and gave a magnificent blaze of bloom. Mr. LYNCH, who has won so much esteem at Cambridge, said he had some difficulty in obtaining a variety to his liking until Mr. BLAIR, of Trentham gardens, furnished him with this one, which he now calls "Blair's Beauty of Trentham." The flowers are of moderate size, intense colour, and have a long spur. The leaves are very small.

CAREX PANICULATA.—In the semi-wild portion of the grounds at the Botanic Gardens, Cambridge, is a specimen of this interesting plant that well illustrates its peculiar root-growth. The specimen has an upright stem 3 feet high, which consists of closely-packed roots. That this is not a proper stem only becomes apparent after close observation, as the drooping foliage screens the lower portion of the plant from view.

MR. B. HARTLAND'S NEW NARCISSUS.—The pretty variety of Narcissus figured by us in our last issue, p. 283, has been distinguished by the name Parmenia by its raiser.

METROPOLITAN OPEN SPACES.—There is some prospect of Lambeth Palace Gardens being added to those now under the care of the London County Council—at least, permission has been given for volunteers to drill there, with a hint at the possibility of a wider use. What a boon this would be for the neighbourhood! only the inhabitants thereof can form an adequate idea. We know what is said to attend on a healthy body; and this concession on the part of a great ecclesiastical authority would show the existence of a healthy mind. The London County Council have acquired the famous Elizabethan mansion and park at Bromley, which will as soon as possible be placed at the service of the community. We understand that some 16½ acres in extent have been secured in what is called Upper Sydenham, to be opened in the course of the ensuing summer as a recreation-ground. In Deptford a children's gymnasium has been opened, and another at Cable Street, Shadwell. Again, between Wandsworth and Putney, on the river banks, 19¾ acres of land has been secured, and will be opened as Wandsworth Park, some nine months hence. An area of about three-quarters of an acre has been formed out of what was the forecourt of Aske's School, in Pitfield Street, near Shoreditch Church; and there is another small plot in course of transformation in Ivy Street, not far from the latter. A small pleasure-ground is now being arranged at Bromley-by-Bow. Another public garden is that known as Northbrook Park, now in the hands of the County Council. There are 17 acres of grass-land at Lea, given by Lord NORTHBROOK. The Council, in conjunction with the vestry of the parish of Lea, have agreed to purchase Manor Park, 9¼ acres, and the old Manor House, Lord NORTHBROOK'S birthplace. All this indicates progress in a healthy direction.

MR. GEO. SAVAGE, whose death is recorded in the American journals, was one of the most distinguished Orchid cultivators in the United States. Deceased was born in Warwickshire, England, fifty-four years ago, and after employment for a time in several private establishments here, emigrated to America, and served in Mr. GEO. SUCH'S establishment at South Amboy, New Jersey, and other nurseries. But it is mainly in connection with the collection of Orchids belonging to the late W. S. KIMBALL, of Rochester, N.Y., that deceased was best known on that side of the Atlantic. Under Mr. KIMBALL, he formed a collection second to none in the States, and produced a number of hybrids. His name is commemorated in Cypripedium Savageanum.

THE FLORISTS' MUTUAL FIRE INSURANCE ASSOCIATION, that had been established in the United States of America, has just dissolved. Much regret is expressed in the American journals; the florists and horticultural trade generally are blamed for the disinterestedness and apathy they have shown in the matter, and they are warned that many will live to regret their inaction. Quite contrary experience has been our own Nurserymen's, &c., Hailstorm Insurance Corporation, which appears to have received very satisfactory support indeed.

VEGETABLE PATHOLOGY.—M. G. STAES, of the University of Ghent, has recently published an interesting article on the science—phytopathology. The Krundkundig Genootschys Dodonæa, at Ghent, has done most to familiarise us with the new science. In fact, this society has for some time made a study of phytopathology; but only since the end of 1892 has publicity been given to the fact that the society on application was prepared to furnish, gratis, information on any subject relative to the diseases of plants. A comparatively large number of applications has been received—over a hundred since 1894. It has, further, been arranged that at Ghent, Alost, and Turnhout, where public instruction is given, a certain number of lessons relative to plant diseases shall be included. In 1894 there was a public course devoted to the diseases of plants. M. G. STAES has been entrusted with the organisation of these lessons. In 1895 the Société Dodonæa started, in connection with the Phytopathologisch Laboratorium at Amsterdam, a journal *Tijdschrift over Plantenziekten* (*Journal of Plant Diseases*), under the editorship of Professor RITZEMA BOS and M. G. STAES. This publication is in its fifth year; it is illustrated, and issues plates. At the Agricultural Institute at Gembloux, phytopathology forms part of the course of instruction; but at the State horticultural and agricultural schools the study of injurious insects and of cryptogamic diseases is made of less importance.

LECTURES ON THE EVOLUTION OF PLANTS.—Prof. D. H. CAMPBELL has published through MACMILLAN & Co. a series of lectures delivered by him at the Leland Stamford Junior University. Beginning with the simplest forms of life, the author passes in review the various groups of plants. Prof. CAMPBELL considers the Volvocineæ to represent more nearly than any existing forms the ancestral type of all the higher green plants. From it have arisen a number of independent lines of development resulting in very divergent types of structure. The first step is the loss of motility in the vegetative cells. Then come the beginnings of a distinction between vegetative and reproductive cells, and the arrangement of cells in threads or thalli. The varying arrangements met with among Algæ are summarised, the red and brown Algæ being considered to represent the highest expression of their respective lines of development. The higher green plants are considered to have originated from the simple fresh-water green Algæ, and so we pass from Mosses and Liverworts to Ferns, Conifers, Cycads, and flowering plants. Plants, in fact, "have succeeded in adapting themselves to almost every environment. From the open ocean to arid deserts and lofty mountain tops, some plants have succeeded in establishing themselves, and from the equator to the poles no district is completely wanting in some types of vegetable life." These are very interesting matters for speculation, and their discussion cannot fail to elicit further information and to correct error.

A MONUMENT TO THE LATE BARON VON HÜGEL.—A flower show, under the patronage of the PRINCESS METTERNICH, was held in Hietzing, near Vienna, on Thursday, May 11, which was instituted by the gardeners and garden-amateurs of this pretty suburb of the Austrian metropolis, for the purpose of obtaining funds wherewith to erect a monument to the memory of the renowned traveller, discoverer, and horticulturist, the late FREIHERR KARL ALEXANDER VON HÜGEL. One of the main ideas of the exhibition was to exhibit most of the plants wherewith HÜGEL enriched European gardens, a collection of which has been carefully cultivated in the imperial gardens at Schönbrunn, and in those of

Graf Harrach, at Bruck, on the Leitha. The amateur's and gardener's club were so fortunate as to obtain, for the site of their show, the glasshouses and garden in which, in the forties, the flower-shows of K. A. von Hügel took place, and which had such great attractions for the Viennese. This garden passed on Hügel's removal to Florence in 1849 into the possession of Prince Wrede, and later into that of the Duke of Cumberland. This possessor soon sold it, and so it came into the possession of Dr. Ehrenfeld, who, in the friendliest manner, allowed the show to be held therein.

Apples from the Antipodes.—The inland traffic manager of the Orient line of Royal Mail steamships informs us that the *Ophir* is now on her way from Hobart, &c., to Tilbury Docks, with 24,000 cases of Apples.

Gardening not Healthy.—Gardening is generally considered one of the healthiest of occupations, but the German Gardeners' Association has issued a warning to those who intend entering the industry. They cite the fact that during the years 1887 to 1897, of the 291 members of the Association who died in Germany, not fewer than 142 succumbed to consumption and other affections of the lungs.

De Langhe's Cyclamen papilio at Antwerp.—The progress made with this extraordinary strain of Cyclamen during the last year is very great; the flowers which M. de Langhe showed at the Drill Hall last year had more or less of a drooping habit, which English florists object to, but now the blooms are much more upright, and the whole habit of the plants has improved. Nothing could possibly have been finer than the group shown at the Antwerp exhibition, and he deservedly received a large Gold Medal, and for the cut flowers a Silver-gilt Medal.

Stock-taking: April.—This month we have again to note a falling-off in the value of imports to the amount of £889,694—that is to say, the imports for last month amounted to £39,357,000, against £40,246,716 for the same period last year. The items of decrease are:—Animals, living, for food, £18,627; duty-free food, £1,284,380; Tobacco, £30,255; chemicals, &c., £14,777; raw materials for textiles, £1,276,812; and Parcel Post, £1,062. Barley fell off £328,387; Wheat gave way £626,515; and Oats record a drop of £144,252. The import of cotton fell away by some 863,668 cwt. (value £1,520,288); the reduction in Jute is £47,186. Wool increased its value by £37,487. The increase is in oils, metals, caoutchouc, wood and timber, tallow, manures, &c. It may be noted that we imported Clover and grass-seeds to the value of £52,282; Flax or Linseed, £263,878; Rape-seed, £16,873. Of paper-making materials, Esparto and other vegetable fibres, mounted up £77,035; pulp of wood, chemical and mechanical, £140,824; wood and timber are valued at £376,275, against £388,425 in April, 1898. The following are our usual quotations from the summary table for the past month:—

Imports.	1898.	1899.	Difference.
	£	£	£
Total value ...	40,246,716	39,357,022	—889,694
(A.) Articles of food and drink — duty free	14,262,300	12,077,920	—1,284,380
(B.) Articles of food & drink—dutiable	1,899,372	1,951,532	+52,160
Raw materials for textile manufactures	7,610,695	6,333,883	—1,276,812
Raw materials for sundry industries and manufactures	3,441,017	3,934,956	+493,939
(A.) Miscellaneous articles	1,174,175	1,323,463	+149,288
(B.) Parcel Post ...	99,117	98,055	—1,062

We now make room for the figures connected with fruits, roots, and vegetables, suggesting to the authorities that they might with advantage to both producer and consumer gather more ample statistics. A lot of Spanish Asparagus has made its way to the markets, lacking mention of place of origin.

Imports.	1898.	1899.	Difference.
Fruits, raw:—			
Apples ... ... bush.	167,121	148,878	—18,243
Cherries... ... ,,	...	24	+24
Grapes ... ... ,,	2,259	1,626	—633
Lemons ... ... ,,	135,486	201,326	+65,840
Oranges ... ... ,,	589,337	1,023,171	+433,834
Pears ... ... ,,	1,355	957	—398
Plums ... ... ,,	1	...	—1
Unenumerated... ,,	63,760	86,029	+22,269
Onions ... ... ,,	613,633	639,183	+25,550
Potatos ... ... cwt.	1,186,653	514,748	—671,905
Vegetables, raw, unenumerated ... ... value	£131,952	£149,367	+£17,415

The value of imports for the past four months is put at £157,551,443; and this compared with £159,317,623 for April last year, shows a decrease of £1,766,180. Coming now to—

Exports,

we have to record an increase of £1,961,435, that is to say, in April last year the total was £17,496,011, the figure for last month was just £19,457,446. Coals, &c., figured largely in the increase in raw material exported, as does also wool; yarns and textile fabrics went up by £625,539; new ships were exported to the value of £492,365; metals, and sundry manufactures therefrom, increased by £193,351; machinery and millwork advanced by £11,288; articles of food and drink increased in export and value by £54,376. By the way, an inquirer into the export of confectionery, &c., states that he found these were placed to the credit of pickles in the records of the Board of Trade! The Canadian preferential tariff does not appear to be so much appreciated as it might be, so says the Finance Minister of the Dominion; exports to that part of the world, however, are gradually swelling in volume: of the four months just ended we note the exports have achieved £81,511,487, against £75,203,129 for the same period last year—or a gain of £6,308,358. This looks very well indeed, and with a clearer political outlook all round even better results may with safety be anticipated.

The Fifty Best Orchids at the Ghent Show.—M. A. A. Peeters, nurseryman, 62, Chaussée de Forest, Ghent, writes: "I am happy to inform you that the fifty best Orchids that were exhibited at Mont St. Amand belong to me."

Reduction of Working-hours in Nurseries.—A valued boon has been conferred on their *employés* by the nurserymen in the Woking district, in the reduction of the hours of labour on Saturdays. Through the cordial co-operation of the heads of the various establishments, the working hours on that day have been reduced one and a half hours, viz., from 5.30 to 4 p.m. This concession by the nurserymen will do much to foster a friendly feeling on the part of their men, and is an example which might be copied with advantage by other establishments throughout the country.

The Nightingale is not altogether unknown to London suburban districts. On Wednesday evening last, at 11 p.m., we had the pleasure to hear this delightful bird singing beautifully at the extreme corner of Wimbledon Common, adjoining Putney Hill, and scarcely a mile from the High Street. The bird was resting in a Birch tree not many yards from a lighted street-lamp.

Publications Received.—*Roses and Rose Culture*, by William Paul (Simpkin, Marshall, Hamilton, Kent & Co., London). When we say that this is the ninth edition (tenth thousand) of this shilling illustrated handbook, we have sufficiently set forth its use and value.—*Agricultural Journal of the Cape of Good Hope*, March 30. This contains, among other articles, a good paper by Mr. Thos. Sims, on the Elementary Principles of Sylviculture or Woodcraft.—*Proceedings of the Agri-Horticultural Society of Madras*, October-December, 1898.—*Annual Report for* 1898 *of the Botanic Gardens, Straits Settlements*, by H. N. Ridley, director. This includes some notes by Mr. C. Curtis on a Botanical Tour in Perak.—*The Fern Bulletin*, Vol. VII., No. 2, April (quarterly).—*Société Nationale d'Horticulture de France*, Liste générale des membres de la Société. Arrêtée au April 1, 1899 (Paris).

PLANT PORTRAITS.

Cienkowskya Kirki.—An East African Scitamineous plant allied to Kæmpferia, and not far from Ginger (Zingiber). It bears large violet flowers with a yellow centre. *Revue Horticole*, April 1.

Diervilla Wagneri ×.—A cross between D. florida and D. Middendorffiana, *Gartenflora*, t. 1461.

Helenium autumnale superbum, *Garden*, April 1.

Pear Doyenné d'Alençon, *Bulletin d'Arboriculture, &c.*, April.—An early variety, of excellent quality.

Rhododendron diversifolium ×.—Said to be a hybrid derived from R. arboreum. Some of the leaves are linear, others oblong, and the numerous rose-coloured flowers are in terminal clusters. *Wiener Illustrirte Garten-Zeitung*, April.

Solidago nemoralis, Aiton, *Meehans' Monthly*, April.

HIPPEASTRUMS (AMARYLLIS) AT WESTONBIRT.

For many years the late Mr. Holford took great interest in the cultivation of Hippeastrums, and half a century ago he purchased the following species:—aulicum, reticulatum, pssitacinum, solandriflorum, stylosum, Johnsoni, and some of the best hybrids from the noted collection of the late Mr. Sweet, of Clifton, Bristol. By crossing and intercrossing these, some pretty hybrids were obtained, but the constitution of most of them became weak, especially those having high-coloured flowers, and it soon became needful to employ a more robust species in order to strengthen the constitution of the strain. Consequently, in 1870, H. pardinum was purchased. The flowers of this species are 6 inches in diameter, creamy-white in colour dotted over with crimson, and having scarcely any tube. This species was employed as a male parent, which improved both the constitution and also the form of the flowers. In 1879, a variety named William Pitt was added to the collection; the flowers of this were small, of a shade of scarlet, with a broad white stripe up the centre of the segments. This variety when crossed with the best of the seedlings, gave added brilliancy of colour to the larger flower. A species named Leopoldi was next purchased from Messrs. Veitch & Sons, Chelsea, and this, when crossed with other varieties, gave a roundness of form to the segments, but the first crosses from these did not possess the enduring property of the flowers of the older varieties, and until further and distinct crosses were made, good constitution and substance, and colour in the flowers were not obtained. In 1880 H. Empress of India was purchased, this fine-constitutioned plant proving an excellent parent, and imparting vigour to our best seedlings. Out of the thousands of seedlings raised, only those of perfect form, good substance, and pleasing colours are retained and named; and these at the present time number about 300, and includes flowers of a variety of shades of colour and markings. The shades of crimson, scarlet, and the white grounds, flowers flaked and veined with scarlet, rose, purple, and vermilion, are of perfect shape and good size, but the white form raised some years ago has not in its numerous seedlings improved in either of these points. Seedlings are raised which flower in three years, the seeds being sown as soon as they are ripe (which is generally during the month of May), in pans or boxes of light sandy soil, placing these in a brisk moist heat to germinate. As soon as the bulblets are formed they are potted in 3-inch pots, three plants in each, kept growing in a gentle heat without a check, and not drying them off till they become large enough to occupy 6-inch pots. The compost used for their final potting consists of three parts fibrous loam, one part leaf-mould, some silver-sand and charcoal to keep it porous; and in this they are first flowered and proved. After flowering, they are grown on till they have completed the two centre leaves, then gradually dried off at the roots, and exposed to the full sunshine. This is found to be beneficial to the bulbs, and they flower strongly the next season. They are wintered in a dry, airy position, withholding water until the time of starting. The house illustrated (fig. 108) is 56 feet long, and 24 feet wide, having a wide central pit, and two narrow side-pits, which contains about 2000 bulbs in pots plunged in the beds. This house was erected by Captain Holford for the special purpose of growing Hippeastrums, and he takes the greatest interest both in the selection of the parent-flowers in crossing, and the special cultivation of the plants.

FLOWERS ON MIDSUMMER SHOOTS OF THE APPLE AND PEACH.

THESE are not uncommon, but when they do occur, they are generally double-flowered by multiplication of petals, or by the substitution of petals for stamens. Moreover, the Apple proper is not formed. A similar state of things occurred in the Peach of which we now give an illustration (fig. 109). It was formed at the end of a young shoot, its five sepals were replaced by leaves, the petals were increased in number, but the true carpels were not present. The specimen was kindly sent to us by Mr. Balderson, of Hemel Hempstead.

PENCILS AND OF WHAT THEY ARE MADE.

THERE are few more useful articles in the world than a blacklead-pencil. While most other things have their seasons of prosperity or usefulness, a blacklead-pencil is always with us. Yet there are times, we are informed, by those who ought to know, namely, the makers, when there are greater demands for these useful little articles than at others. For instance, at the time of a general election, the homely pencil is fulfilling a great work, and the destiny of the country, it may be, is dependent upon its use in the ballot-boxes. But there are other seasons also when pencils of a different character are much in demand—we mean at the season from which we have now emerged, when no ball-room or dance-programme is complete without its daintily-finished appendage, the pencil.

Under these circumstances, the history of the birth and growth of a blacklead-pencil, as seen by me at Messrs. E. Wolff & Sons, Falcon Pencil Works at Battersea, may be of some interest, more especially as wood, though perhaps not the primary material in its composition, is by no means an unimportant factor. But there are woods and woods used in pencil-making; and though of late years many new woods have been tried, the so-called Pencil-Cedar still maintains its superiority over all others, and is always used for pencils of the best quality. The reason for this is obvious, for anyone who knows anything of the nature of woods will at once own that no other wood equals it in the ease with which it can be cut, as well as in its straight grain and absence of knots. It is the Juniperus virginiana of Linnæus, and is the most widely distributed of North American Coniferæ, being found, according to Prof. Sargent, in Southern New Brunswick, shores of Georgian Bay, Northern Michigan, Northern Wisconsin, and Minnesota, South, to Cape Malabar and Tampa Bay, Florida, and the Valley of the Colorado River, Texas, West to Eastern Nebraska, Kansas, and the Indian territory to about the 100th parallel of west longitude; in the Pacific region, Rocky Mountains of Colorado to Vancouver's Island, British Columbia, not extending to Western Texas, California or Oregon; in Utah, Nevada, and Arizona rare and local. The tree grows to a height of about 80 feet, and to a diameter of about 3½ feet. In America the wood has a variety of uses, such as the construction of posts, sills, railway ties, and for cabinet-making, and it is said to be durable underground.

It is the wood of this tree, then, that is always used for the best pencils, and on my visit to the works before-mentioned, I saw under shelter of a roof in the yard, a large quantity of huge logs, some perfectly sound, while others showed knots and shakes, and others again a large proportion of decay, the work of the spawn of a fungus. These logs have to be very carefully overhauled, and the close even-grained wood is alone selected for pencil-making. Pencil Cedar comes into England in very large quantities, always in the form of logs, and is shipped mostly from Florida.

[Juniperus virginiana, the so-called Red Cedar, is not only widely distributed, but it runs into numerous varieties, some of which are in cultivation. Some of these varieties are thought sufficiently distinct to be counted as species. Professor Sargent, we believe, considers the Florida form to be worthy of a specific name. We may here remark that a specimen sent us lately from Florida by Mr. Thomson seems to be identical with the form known in gardens as J. Schotti. The Bermuda Cedar is closely allied to the Juniperus virginiana, but differs from it. It might be utilised for "Cedar" pencil-making. The Jamaica form, specimens of which were sent to us by Mr. Fawcett, are so like J. virginiana that we should assign them to that species. We presume the wood of the Jamaica tree would be equally serviceable; in any case, it is worth trying to ascertain whether another minor industry might not be added in Bermuda, Jamaica, and other islands in the West Indies. ED.]

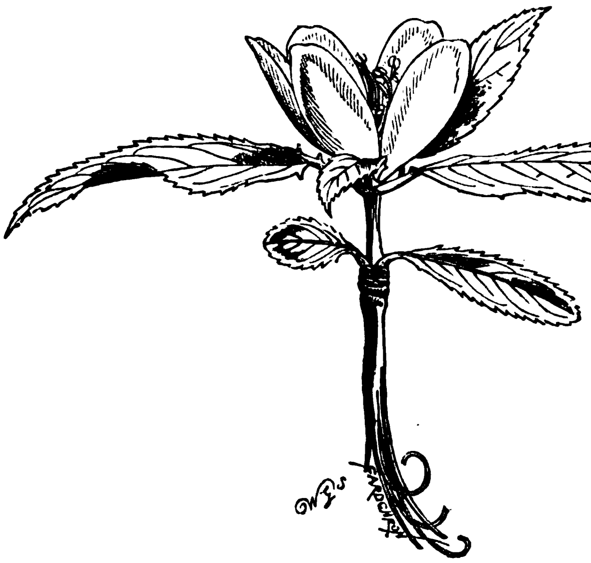

FIG. 109.—PEACH BLOSSOM ON SUMMER SHOOT: SEPALS LEAFY; PETALS AND STAMENS NUMEROUS; PISTIL ABSENT.

Before proceeding to the inside of the factory, I noticed in the same yard, where the timber was stacked, a number of casks or hogsheads, which were filled with plumbago, or as it is commonly called, black lead. This was in a crude form, just as it comes from the mines, and as it is imported from Spain, India, Mexico, and Ceylon. Besides this, there was a large stock of "pure Cumberland lead," which I was informed was purchased many years ago by the firm, and is very highly prized by them, as it produces the best pencils that can be made. A cask of plumbago is like so much coal-dust, mixed with lumps of irregular sizes. Passing into the factory we find a powerful crushing machine, into which the plumbago is put and crushed, or ground to an impalpable powder. It is next made into a thick paste under heavy rollers, and if it were brown instead of black it might readily be mistaken for chocolate paste. Very great care and expert knowledge is required in preparing this paste; the least coarseness or grittiness would, of course, spoil the pencil, and the substance has to be specially prepared for the different grades of hard and soft leads. When it is sufficiently prepared it is placed in a kind of cylinder, with a small opening at the bottom of the diameter of the lead required for the pencil, either round or square. The cylinder is attached to a powerful machine, and an enormous pressure is brought to bear upon the contents, so that the lead in its plastic state is squeezed through the aperture at the bottom of the cylinder, and comes out in the form of a long black cord—more, indeed, like a strip of india-rubber than anything else. It is taken by girls, who sit at tables immediately contiguous to the machine, and laid in grooves on a thin plate, each strip being cut off of uniform length with a knife. These strips are then removed to a kind of oven, and submitted to a process of drying or baking, until they become hard; they are then ready to be placed in their wooden cases, which are prepared by first planing the wood to an uniform thickness—namely, half the thickness of the pencil, sufficiently wide to cut six pencils, and of the length required, for pencils vary both in length and thickness. Six grooves are then cut longitudinally and simultaneously by a machine, either half round and of the depth and diameter to fit the lead, or square, according as the pencil is to have a round or a square lead. The dried or baked leads are next taken, six at a time, and dexterously laid in the grooves made in the wood, and when so placed by one set of girls, are passed on to others who take a correspondingly grooved piece of wood, and brushing each piece over with glue, bring the surfaces together. A number are then placed in a small screw-press and submitted to very heavy pressure. So neatly is this joint effected, that it is often difficult to find it in a finished pencil. When the glue is set and quite hard, they are removed to a machine which ploughs the wood out between the leads, cutting it half-way through; by turning it over and repeating the operation on the other side, the wood is cut quite through, and the six pencils all fall out in their cylindrical forms. All this is done with wonderful accuracy and rapidity. The pencils are next rubbed down with glass-paper to remove any roughness, and to give them a perfectly smooth surface. Though this may be the finishing touch of many pencils, a large proportion of them are now polished or stained in various colours, and then polished. This is all done by machinery, the pencils being really French-polished, and not varnished. The final touches consist of cutting off the ends, pointing, and stamping the maker's name.

At the time of my visit, a large number of girls were employed in making the dainty little white pencils for ball programmes. Some were fixing the enamel-like coating over the slender Cedar-wood; others were fixing the ivory or bone tops, and others again were attaching the white silken cords and tassels.

As some indication of the extent of the pencil manufacture, I may say that the stock of "leads" stored away in boxes at the factory at the time of my visit, and ready to be placed in their wooden receptacles, was estimated at many hundred thousand gross.

The pencil manufacture was at one time carried on at Keswick, in Cumberland; but I am assured that at the present time little is done there, but that the principal factories are in the neighbourhood of London, and that which I had the privilege of visiting is the largest. Though pencils are made on a large scale in Bavaria and other places on the continent, it is satisfactory to know that those of English make are of the best quality in the market.

An interesting branch of the pencil manufacture is, that the resulting chips and shavings of the Cedar are not absolutely waste products. The wood, as is well known, contains a quantity of very fragrant oil, and the cuttings are all very carefully collected, and sold to the chemists and perfumers for distillation.

Though, as I have before said, other woods than that of the Pencil Cedar have been, and are still, sometimes used, such as Lime (Tilia europea), and American Redwood (Sequoia sempervirens), yet no wood equals that of Juniperus virginiana, either for ease in cutting, freedom from cracking or warping, or adaptability for finish. *John R. Jackson, Museums, Royal Gardens, Kew.*

LILIUM AURATUM IN SCOTLAND.

In the months of August and September last year, visitors to the watering places on the shores of the Firth of Clyde flocked in large numbers to see a grand example of the golden-rayed Lily of Japan, Lilium auratum, growing in the small garden in front of Darroch-dhu Cottage, Dunoon, the residence of Mr. James McGibbon, to whom we are indebted for the accompanying illustration from a photo (fig. 110), showing the stately proportions of the handsome specimen. The figures in the photograph, among whom Mr. McGibbon is seen on the right, give a good idea of the size and stature of the plant.

The history of the specimen given to us by Mr. McGibbon is rather interesting, although simple enough. He bought the original bulb, in a bag containing a dozen, in Messrs. Hutchison & Dixon's Public Sale Rooms, Glasgow, six years ago, the cost being 3*s*. the lot, or 3*d*. the bulb. This particular bulb he planted soon afterwards in his garden at Dunoon, where it has grown and thriven ever since without more than a slight protection from severe frost in the winter.

In 1897, it sent up sixteen stems, which bore 292 blooms, and drew a considerable amount of attraction from visitors to the pretty watering-place. Last year it produced twenty stems, carrying the enormous number of 428 fully-developed flowers; and another stem, which bore twenty-five perfect flower-buds, got injured near the base, and had to be removed, which, had it come to maturity, would have given a total of 453 flowers—a number probably unprecedented on a plant grown in the open air in Scotland. The stems ranged from 5 to 7 feet in height, and the thickest girthed 3¼ inches at the base, and bore forty-three perfect blooms. One malformed flat stem carried as many as sixty-one flowers, all fully developed, but smaller than the others, and made a very pretty show while in bloom. Other stems bore from ten to twenty or thirty flowers, and the gay show they made can be easily seen in the illustration, although it cannot convey to the senses any of the rich odour dispersed around in the early morning and at dewey eve. Travellers who had seen the golden-rayed Lily growing in Japan, India, California, and Australia, as well as in European gardens, all declared they had never seen such a grandly-developed plant, and visitors to the Clyde during the coming autumn would do well to keep it in mind. *Scotus.*

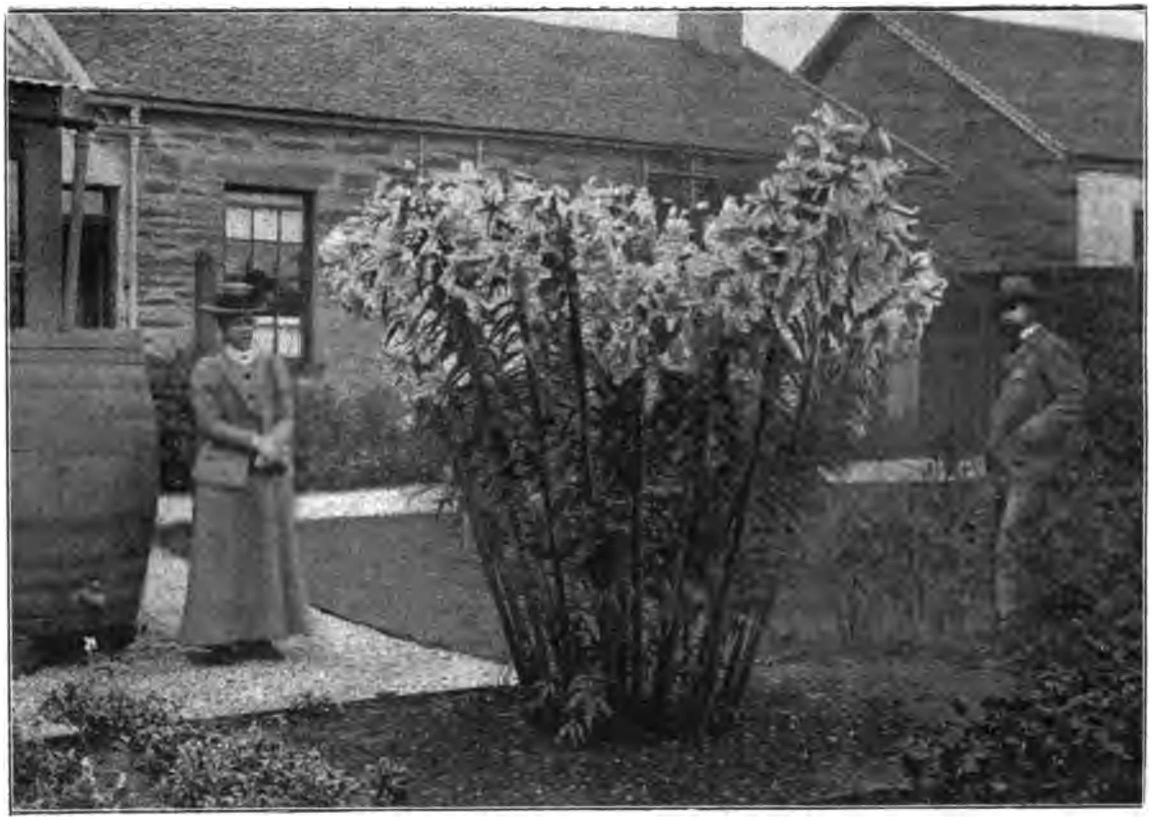

FIG. 110.—LILIUM AURATUM IN SCOTLAND.

HOME CORRESPONDENCE.

GARDEN PESTS.—I received from Mr. Geo. Lamb, of the University Botanic Garden, Cambridge, a number of Tulips which were supposed to be suffering from growing in the shade of an Apple-tree. The bulbs were badly decayed, and were found on examination to be suffering from the attacks of five different pests, any one of which would have been sufficient in itself to cause the blight. These pests were: 1, Julus pulchellus, a pretty but very destructive millipede, known to attack Celery, Cabbages, Wheat, and almost every kind of cultivated plant. 2, Acarus, or bulb-mite; this is allied to the bulb-mite which wrought so much mischief among Eucharis Lilies a few years ago. 3, Larva of a beetle; there are many species of beetle, as of acarus, which prey on cultivated crops and plants; all are to be carefully guarded against. 4, Nematode worms of microscopic dimensions, but none the less destructive because they are small and able to carry out their operations unobserved. 5, Enchytræis parvulus, the Aster-worm described by me in these columns Aug. 14, 1897. This small white worm is now found to be ubiquitous, and while it serves a useful purpose as a scavenger, as I have recently been able to demonstrate, it becomes very injurious when it gets into flower-beds and kitchen gardens. The case of the Tulips is hopeless. All decaying and affected material should at once be burnt, the plots frequently dug, and treated with lime, salt, nitrate of soda, or other insecticide. No highly cultivated plants should be set in the same beds till the latter have been disinfected. Care should also be taken when any new application of manure or fertiliser is made. The gardener should always see to it that mould, decayed vegetable matter, manure, and other materials used are freed from these pests before they are applied to beds or mixed in the flower-pots. Waste materials reserved for fertilising should be mixed with gas lime, salt, or other remedies against these minute but ever-to-be-dreaded enemies of horticulture. I shall be glad to report on other cases, but must ask all correspondents who wish their consignments acknowledged to enclose stamped envelope for reply. *Hilderic Friend* (*Rev.*), *Ocker Hill, Tipton, May* 3.

BIRDS AND FRUIT-TREES.—I can assure my friend, "R. M." (*Gardeners' Chronicle*, p. 268), that the tomtit really does destroy the somewhat advanced buds of the Pear. This year these birds have been very destructive, and I and the men working in the fruit-garden have watched them at a short distance, and upon examining the spot immediately we have found the destroyed buds on the ground beneath the trees. No trace of any insects could be found in the remaining buds. The past year or two the birds have destroyed nearly the whole of the buds of our white Lilac and double-flowering Cherries, and the bushes are half dead as the result. *C. Herrin, Dropmore Gardens.*

—— I do not agree with "R. M., Newbury," on p. 268. I have myself shot tom-tits when pecking at Black Currant buds, and have found the same in their beaks when dead. They are also most destructive to soft Apples, and all kinds of dessert Pears. Last season I was obliged to net my Pears on some trees where I wanted the fruits for exhibition purposes. In the case of some of the trees the net went round them four times, but even then the tits found their way through it. The birds that keep me busy with the gun are bullfinches, tom-tits, blackbirds, thrushes, chaffinches, offinches, and jays. My Cherries are under wire-netting, that is the reason I have not added the starling. I destroy all the birds enumerated above whenever a chance occurs. *E. Coleman, Kent.*

NEMESIAS.—When a few years since Messrs. Sutton & Sons introduced those beautiful half-hardy annuals in variety, known as Nemesia strumosa, the needs of these plants were not fully understood, and they suffered in many gardens from such treatment as raising from seed under glass, then dibbling them out into the open ground direct from the seed-pans. That there is a method of treatment that will ensure entire success is evidenced in a cool greenhouse at Mr. Mortimer's nursery, Farnham, where there are several thousands of plants in luxuriant growth, literally growing like Watercress. The major portion are of the newer compact form, but some are of the earlier and more spreading habit. The plants are in scores, in boxes 12 inches by 9 inches, and 3 inches deep. No doubt it would have been better had there been but twelve plants instead of twenty in each box, but such luxuriant growth as has resulted could hardly have been foreseen. Pricked out more thinly, transplanting into the open ground with good balls of soil and roots would have been easy. These plants, however, are not for this purpose, and possibly they may make a very attractive feature in London a few weeks hence. Seed was sown early in January, and also at the end of the month; but all the plants now are alike, and but for severe pinching would be a mass of bloom. *A. D.*

ALLEN'S EVERLASTING APPLE.—We have grown this Apple here since 1873, and in my fruit record-book the word "None" does not appear, though there are blanks against it in 1876, 1877, 1878, 1879, 1888, and 1893, when I may have failed to enter the date at which the crop was gathered in those years. The latest date we have gathered it was Nov. 19 last year, and the earliest Nov. 7. I put the fruits in a box in the fruit-room, it prevented them from shrivelling. The first week in April (last month) I took out eleven dozen, *i.e.*, five good ones, one dozen that were spotted with decay, and two dozen badly decayed. We are still eating fruits of this variety, and they are mostly unshrivelled. *H. R.*

HOLLAND HOUSE.—The articles in the *Gardeners' Chronicle* upon the gardens at Holland House, reminded me of an account of the history of the place which appeared in the London *Daily News* of October 24, 1889. In this there is a reference to the improvement of the grounds and gardens by Harry Fox, by whom they were acquired on lease in 1749. He purchased them in 1767. Lady Caroline Fox appears to have been the moving spirit in these improvements. Fox's friend, the Hon. Charles Hamilton, of Pain's Hill, "a gentleman celebrated for his exquisite taste in gardening" (Loudon refers to him and his garden in the *Encyclopedia of Gardening*) was consulted, and Mr. Peter Collinson was also called in. Collinson was invited to meet Hamilton at dinner when, as Fox said, in his letter to the former, "Lady Caroline has a thousand questions to ask about flowers, and I not much fewer about plants." In 1750 Fox again wrote Collinson, asking if he could procure some cones of Cypresses, some "Acorns of Scarlet Oak, and a bushel or more of Chestnuts, for sowing." He thought "they are less likely to impose on one so learned than on your ignorant and humble servant, H. Fox." Later, Collinson was again in request, for Fox wrote, "Mr. Watson advised me to sow something with a hard name, to creep on the ground and cover with green all the vacant spaces in my young plantations. I wish you would tell me what it was." On the letter, which, the *Daily News* tells us, is now with others in the MS. department of the British Museum, is endorsed, "Double Snowdrops. To remind him in March to sow Candytuft, Rock Stock, Venus' Looking-glass, &c." *S. Arnott.*

BROCCOLIS.—What has become of the old style of Broccolis? I used formerly to grow a purple Broccoli, with a solid, rather conical, Cauliflower-like purple head [The true Cape Broccoli. ED.], which, when cooked, was green and deliciously "marrowy" in quality, with delicate flavour. Now I can only get seed of sprouting Purple Broccoli, not heads—quite a different thing; and I have had the same sent to me from Northants, excellent as sprouts, but not Cauliflower heads. I used also to grow an excellent vegetable Sulphur Broccoli [This is better known now as "Portsmouth," but it has many synonyms. ED.], very hardy and well-flowered. Now these seem to have disappeared. To me it seems a pity that these old, excellent, and hardy products should be superseded by others which, if more showy for the exhibition-table, are not equal for culinary purposes to the older kinds. Are we not going in too much for the competitive exhibition-table, to the detriment of the dinner-table? Will your correspondent call this a "green-meat" question? *R. Milne-Redhead.*

—— The unfortunate citizen in Londen pent, is, perforce, obliged to make use of such varieties and kinds of vegetables as the market gardeners in their collective wisdom and special knowledge of his supposed tastes, or in utter disregard of them, vouchsafe to bring to the market. In the matter of Broccoli, we have got far away from the delicious early Penzance, which can be had in season by making three sowings, two in April, and one towards the end of May, from October to April. The variety is a small grower with a rather conical head, and being of an erect and moderate growth, it does not need much space in which to grow, say 1½ foot each way. Being less able to withstand frost than some others, I always planted it on a sheltered west border with a high wall behind. The purple Cape is rarely or never seen in London. The plant is hardy, and the head of delicious flavour; and by making more than one sowing, it may be had in season from late October to April. The Walcheren, which is as much a Cauliflower as a Broccoli, is another well-flavoured useful variety, which in the south may be sown as early as March, and as late as May 14. It does not get so large as Autumn Giant if not heavily manured, and is, therefore, a nice variety for the best table; moreover, its flavour is not, then, inferior to a Cauliflower. The same may be said of all Broccolis and Cauliflowers, it is the excessive use of manure that spoils their flavour, and inordinately increases the size of the crowns, besides rendering them susceptible to injury by frost. The Wilcove, Knight's Protecting, and the Portsmouth or Sulphur, seldom come to market, and our tables are consequently the poorer by their absence. *M.*

CULTURE OF CONIFERS.—On page 260 of the *Gardeners' Chronicle* there appeared an extract from a paper on the cultivation of Conifers. The writer there said "Thuya orientalis, however, refuses to unite with this" (Thuya occidentalis). If this be his experience it is totally different to mine. I have grafted T. orientalis on T. occidentalis and *vice versâ*, although I have read and also been told that the two would not unite. Further on Cupressus sempervirens is mentioned as the stock on which to graft the Cupressus family. Surely this is an error, and C. Lawsoniana is intended? C. sempervirens as I know it, is a species of fastigiate habit, a native of the Mediterranean region, and not quite hardy in our climate, therefore totally unfit as a stock for our hardy varieties of Cupressus. *F. Roberts, Winchester.*

THE "CASTOR-OIL PLANT" AT MANCHESTER.—The plant, which appears to be commonly sold in the Manchester markets and by itinerant plant vendors as the Castor-oil plant, is not a Ricinus, but Fatsia (Aralia) japonica. I am informed by a Manchester correspondent that nine out of ten of those who have a Fatsia as an indoor plant, know it as the Castor-oil plant; and the florists in Smithfield and other markets, if asked for such a plant, would give the purchaser a Fatsia. The itinerant plant vendors in Manchester are mainly girls, and, in addition to selling Fatsias as Castor-oil plants, they advise purchasers to pour a dose of castor-oil on the soil occasionally, as this assists the Fatsia in retaining its leaves! It would be interesting to know from what source this custom of giving castor-oil to a Fatsia to enable it to retain its leaves grew; one would think that anything like a frequent application of it to the soil would result in occasioning a consistency anything but favourable to healthy plant life. *R. D.*

CYTISUS SCOPARIUS VAR. ANDREANUS.—The origin of this splendid variety is now well known as having occurred in France some few years ago as a sport from the common Broom—Cytisus scoparius. Up to the present time I have never heard of it occurring in English gardens; but a few days ago, on examining a bed of seedling common Broom, I noticed several plants exhibiting this sporting tendency. To show that these are undoubtedly sports, it is only necessary to mention that the plants in the bed all flowered last season, and none exhibited this characteristic. It is also noteworthy to remark that only on some of the branches was it apparent. I send herewith a few branches for your inspection; and I should be glad to know if any readers of the *Gardeners' Chronicle* have noticed a similar occurrence? In connection with the raising of Cytisus s. var. Andreanus from seed, I have noticed that these flower as a rule much earlier than grafted plants. *E. S., Woking.*

GREEK CURRANTS.—For the past year or two, with the assistance of the Greek Consul-General, we have been enabled to give some particulars concerning the Greek Currant crop—the fall in price and the insufficient market demand. The authorities of the Foreign Office have within the past few days published some interesting details, supplementing notes already published. The industry is in a bad way. Greek eggs are too much in one basket, with the result consequent on a fall. Some fifteen or sixteen years since the Phylloxera ruined French vineyards, and French wine-makers had import arrangements altered so as to admit of the importation of Greek Currants; then was the heyday of that fruit. But the Vine-louse was grappled with—was exterminated; French vineyards were restocked, and prospered; the Greek Currants were no longer required for the production of claret; the vineyards required protection—Currants were shut out; the "good friend" was shown the door, and the Greek grower, unable to find another market, has gone to the wall. It takes five years to set up profitable Currant plantations, and the grower did not care to at once sacrifice his money and his labour, and so the Greek Government enacted that 15 per cent. of the annual crop should be bonded and sold after shipments were finished, for home consumption. There has been a failure in this palliative, and now the Greeks are found to insist on the destruction of this reserve, as Billingsgate salesmen condemn an over-supply of fish to be returned to the sea—dead ! The problem now is, how to make a profit on the present output. Possibly some will advocate the making of claret, getting extra "body" from some other source—perhaps Australia. We can only here express the wish that the Greek agriculturist may find a speedy and effectual solution to the economic problem now set before him for solution. *E. C.*

PRIMULA OBCONICA AND SKIN IRRITATION.—Thirteen years ago I knew a young lady who suffered whenever she touched this plant ; but she was the only member of the family the plant affected. Since that time I have seldom met a person whom it does affect ; but as the irritation is generally felt almost immediately, and each time the plant is handled, it would be an easy matter for any individual to find out for himself. For every one that it hurts there must be a host who feel no ill-effects from it, and why discard so useful a plant simply because someone else has been stung by it ? There is a man in this district who cannot clip Ivy because it makes his face, hands, and arms swell to nearly double their usual size, but we are not thinking of discarding Ivy for that reason. Holly has a bad effect on my own hands and arms, so has the sap of Figs. Violas give me heartburn whenever I am working among them ; but Primula obconica has absolutely no effect upon me. For most purposes, P. obconica is more useful than P. sinensis, and is easier of propagation. *R. E. C.*

—— I have been potting P. obconica by the side of a fellow-workman, and his hands have suffered a great deal. I have never seen or heard of a teetotaller being affected in this manner. *R. E. Brain.*

DOES LAND DETERIORATE ?—The question can be answered yes or no, for land does deteriorate from neglect, starvation, and foulness, and when these three things occur it does so to a great extent and loss, it being unable to produce to its full power. On the other hand, land manured, clean, and well attended to, shows its action on plants by their vigorous growth, and greater productiveness. Liberally-manured, well-tilled, and kept free from weeds, you can plant as long as you choose, and it will respond to the treatment. My experience is practical ; my land has been planted with corn ever since I can remember—Wheat, Barley, and Beans, one after the other, and I never heard my father say other, and that with farmyard manure, the most lasting food for farm crops. Artificial manures may answer, but from my observations at least, not on my land. My neighbour, some years ago, had a great fondness for it instead of the genuine article, and had some sown across a piece of freshly-sown Barley, and it took such an effect upon it, that one could not see any difference between the dressed and the other part of the field. Another gentleman gave me his experience, which was similar. I have an artificial loaf, which looks very nice and real, but it is of no use ; and artificial flowers are showy, but they want a little of Rimmell's scent to them, and what are they as compared with real flowers ? I know there are manures offered for every crop that is grown, but I believe the best results are found in the pockets of those that sell them. For how many crops will one dose of these mixtures last ? does it benefit one or many ? I use the same thing out of my farmyard, solid or liquid, for any kind of crop. I dilute the liquid if I think it is too strong for plants in pots ; but for the arable field or on grass-land I use it just as it is, and very effective manure it is, soon changing the look of the crops. I give it to all kinds of plants that I grow, if I think they require a little assistance. Not being a novice in plant cultivation, I apply manure to exotics or any kind of plants, and if my land will produce good crops year after year that of others will do the same. I was interested in the remarks on manure in the *Gardeners' Chronicle* some time since, and I have taken the liberty to give the experience of many years in manuring, which I am fully satisfied with. My land has produced more than seven quarters of Wheat, and seven of Barley after Wheat, to the acre, which is not a bad result for hard work and good cultivation. *J. C.*

PELORIATE DENDROBIUM.

From the gardens, Mill House, Halifax, we have received a very interesting specimen of Dendrobium fimbriatum, in which the two lateral sepals had assumed the same form and coloration as the lip. The flower (fig. 111), therefore, has three lips, and affords an instance of irregular peloria. The column is erect.

We are informed by Mr. J. A. Woods, the gardener at Mill House, that the growth which carried the flowers was 6¼ feet in length, that the flower-spike had three branches, and that all of the flowers with the exception of three were similarly malformed.

In the case of peloriate flowers of Orchids it is usually the lateral petals which take on, more or less, the form and coloration of the lip, but in a variety of Dendrobium nobile, lately figured, the two lower sepals had become lip-like.

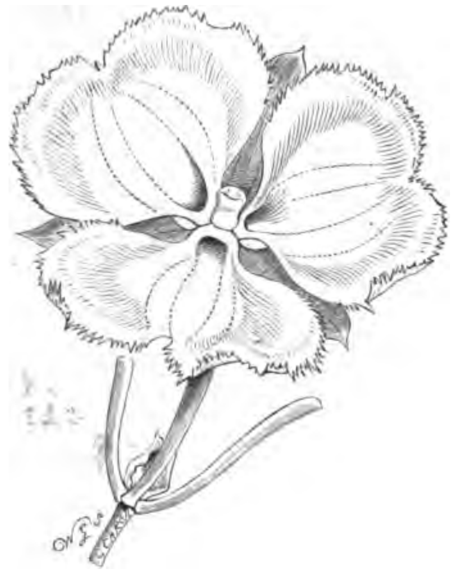

Fig. 111.—Peloria of Dendrobium fimbriatum: flowers yellow.

BELGIUM.

F. SANDER & CO.'S NURSERY, BRUGES.

In our issue for May 14 last year, p. 290, we published a brief account of this wonderful newly-founded nursery at St. Andrée, just outside one of the old gates of Bruges. We mentioned the huge blocks of contiguous houses, some with party walls, and some without any, that were filled to their utmost capacity with Palms, Dracænas, Azaleas, and Orchids chiefly. Much of the stock of plants then existing in the houses have gone to fill the insatiable demand for plants all over the Continent and in America, and yet the houses are as well filled as then. Roughly speaking, Azalea indica are arranged at the present time in the contiguous houses of which mention is made, covering 5 acres of land, cheaply built, light and commodious, with just the requisite heating apparatus, but without any superfluities. Presently the entire stock of Azaleas will be planted out in narrow beds, with brick kerbing, with 2 feet alleys between, filled with the renowned Belgian leaf-mould. As but comparatively few Azaleas are cultivated in pots in the Belgian nurseries, either under glass, or when growing in the open ground, the labour of transferring this immense number of plants is greatly facilitated. The trade in Azaleas is but in its commencement, and new houses for harbouring great numbers are being constructed. Messrs. Sander are not satisfied with cultivating varieties raised by others, but they go largely into the business of raising new ones, and consider themselves extremely fortunate if one in 5000 turns out to be a better thing than any existing variety. It is needless to say, that, all that do not reach this standard are consigned to the rubbish-heap as soon as they have bloomed.

The Palms, which in importance equal the Azaleas, occupy glasshouses covering, at the lowest computation, 1½ acre of land, and they are mostly contiguous with some overhead hot-water pipes, as a means of equalising the temperature ; and, as a whole, they are remarkable for handsome development, abundance of roots, and healthy-looking, handsome leaves. A sickly plant must be a great rarity, and we did not observe one in any of the houses. The plants are plunged in tan-beds in most cases, the smaller in the side beds, and the taller in the central bed, for almost every house is provided with three beds, the middle one being sometimes 12 feet wide. Latanias were in strong force, also Cocos Weddelliana, and Kentias of species. Of the more rare species mention should be made of Livistona rotundifolia, of which there is a great stock of plants, a handsome Palm for table work, Ceroxylon niveum from Columbia, an importation of Mr. W. Bull some years ago, and now obtainable as seed in quantity, a fine species ; Licuala grandis, many fine plants ; Martinisia, with broad handsome leaves and leaflets—new ; a species of Kentia that throws up numerous stems from the root, and has brown-tinted heart-leaf, is a fine Palm ; Kentia Belmoreana Mooreana, has brown ribs and stems, and is valuable for variety ; and of Caryota majestica a fine lot of plants was observed, chiefly young stuff, growing in a house apart. Other species, of which considerable quantities exist, are Chamærops excelsa, French-grown plants, strong, and good ; Phœnix reclinata, P. canariensis, also of the same origin, a most useful Palm that is much in request on the Continent, and of which a houseful of specimens 5 to 6 feet in height, bushy, and vigorous, was seen ; Cocos flexuosa, about as equally popular a species ; Demænorops species, and others.

A houseful of Dracæna stricta plants of a regular height of 2 feet, and perfect in form and leafage, was remarked, as well as a splendid lot of Pandanus Veitchi, another popular plant. Of Dracæna Sanderiana and D. Godseffiana, there were noted great numbers of compactly-grown smallish plants. Anthuriums are cultivated in considerable numbers, and hybridising is constantly going on. A pink-coloured variety of A. Scherzerianum with a double spathe was observed, which has shown this feature constantly for two seasons, will be increased. Orchids are constantly being received in immense numbers from their native countries, some in large masses of 3 feet in diameter, and also as quite small plants, and so generally rapid is the transit in these days, that it is rarely that many are dead or past recovery on arrival. Odontoglossums form the greater proportion of the stock, and an extensive trade is done in cut blooms of this genus. Some of the finest O. crispum in the possession of the firm are probably unmatched, the natural hybrids being of special beauty. Of other species there were fine forms visible, and mention should be made of a natural hybrid of O. cirrosum, which is said to be the finest that a collector has ever discovered in regard to the size, form, and markings of the flower. It will doubtless arouse much admiration when it is brought over to the next Temple Show. Beautiful varieties of O. triumphans and of O. Halli were noted. A very beautiful natural hybrid of O. Halli and O. luteo-purpureum, lip white with a semicircular line at the base ; sepals and petals dark brown, and the width of the flower about 5 inches, was pointed out to us.

Of Cattleyas in species, thousands can be seen in all stages, including a quantity of C. Harrisoni. Thousands of plants of Cattleya labiata, newly imported, were spread out on benches in the houses. Lælia anceps were very numerous, and we cannot remember to have observed stronger or healthier specimens of L. purpurata.

It was remarkable to observe how the Orchids formed a net-work of the healthiest roots in the leaf-mould of the country, sphagnum-moss being only employed as a top-dressing, and as a means of judging the condition of the whole mass in reference to moisture. A fine stock of Sweet Bays as pyramids and standards were noted in all stages of development, from the rooted cutting up to the perfect saleable specimen, and growing in the open ground and in tubs and pots.

As showing the manner in which every available space is turned to use in this remarkable nursery, beds for the germination of Palm-seeds occupy the spaces under the stages and lateral brick-pits in all the houses in which Palms are grown, as well as in many others.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

Present: Dr. M. T. Masters (in the chair); Prof. Church, Mr. Sutton, Rev. W. Wilks, Rev. Prof. G. Henslow (hon. sec.).

Cattleya Malformed.—Dr. Masters exhibited a blossom having only one petal, one sepal, and a straight column. This reduction to a symmetry of "two" is not uncommon in Orchids.

Parasitic Fungi.—Some interesting communications, with specimens of Polyporus ulmarius, showing how it appears to cause the decay of the interior of the tree, and fructifies in the hollow, were sent by Dr. Plowright; also descriptions of parasitic fungi on Alders and Willows. Figures of these will appear in the *Gardeners' Chronicle* shortly. A vote of thanks was given to Dr. Plowright for his communication.

BRISTOL & DISTRICT GARDENERS'.

At the annual meeting held recently at St. John's Parish Room, Redland, Mr. W. A. Garaway, who presided, stated that the Society, though started only a year ago, now numbers over 100 members. Meetings are held, and lectures given on subjects of interest to horticulturists, the average attendance being seventy. Mr. H. Cary Batten was again elected President.

WARGRAVE AND DISTRICT GARDENERS'.

May 3.—On the above date, Professor Groves, F.L.S., gave a lecture on "Mosses," tracing the similarities and differences between them and Ferns in a very clear manner.

The way in which the moss-plant produces spores for reproduction, and the quick growth of the plant, by which large patches of land are covered in a short time, were carefully explained. The reasons why moss is always found in damp places were pointed out; and the diagrams explanatory of the lecture were most useful.

Mr. T. Haskett, gr. to J. W. Rhodes, Esq., Hennerton, exhibited some beautiful Rhododendrons, which were much admired.

NATIONAL AURICULA.

(Northern Section.)

May 5.—The annual exhibition was held on the above date in the Coal Exchange, Manchester. Notwithstanding the lament of our old friend Mr. D'Ombrain, that "the popularity of the Auricula is on the wane," there can be no doubt the Auricula has still many enthusiastic votaries in the North, who love the flower well enough to give it all the attention so essential to its well doing.

On this occasion the quality of the flowers was of a high order of merit, bearing in mind the very treacherous season that has been experienced. As old Ben Simonite remarked, "they had every reason to congratulate themselves, both on the quality and quantity of the exhibits." General regret was expressed at the absence, through indisposition, of the Rev. F. D. Horner, whose plants are always an interesting feature of the show. Over 600 plants were staged, and the principal prize-winners were Mr. T. Lord, Todmorden; Mr. B. Simonite, Sheffield; and Mr. A. R Brown, Birmingham.

New exhibition varieties were exhibited by Messrs. Lord and Simonite, Mr. Simonite showing a very fine, new, green-edged variety of great promise.

New alpines were shown by Messrs. R. Gorton, Eccles; and R. Holding, Birmingham.

The best six Auriculas, dissimilar, were from Mr. T. Lord, Todmorden, who showed Geo. Lightbody, Acme, F. D. Horner, R. Headley, Mrs. Potts, and Abram Barker—a fine lot; 2nd, Mr. Ben Simonite, Sheffield.

or four Auriculas, dissimilar, Mr. T. Lord was again 1st, and Miss Woodhead 2nd.

The best collection of six Alpines (six dissimilar), was that from Mr. A. R. Brown, Birmingham; and for four Alpines (distinct), those of Mr. J. Beswick.

The premier Auricula was Mr. T. Lord's Abram Barker (First-class Certificate); and the premier Alpine, Mr. A. R. Brown's J. F. Kew.

Mr. Frank Law, of Sale, exhibited a fine collection of Narcissus.

Obituary.

Malcolm Dunn, V.M.H.—Just before going to press we are shocked by the news of the death after twenty-four hours acute illness, of our valued contributor, Mr. Dunn, head gardener to the Duke of Buccleuch, Dalkeith Palace, since 1871. We are unable, for the moment, to write more than an announcement of this sad event, but in our next issue we hope to give some particulars of the life and work of this excellent gardener, who for many years has been the best known of Scottish horticulturists. His extreme willingness to assist every deserving cause was most remarkable.

T. A. Dickson.—It is with deep regret we learn of the decease of Mr. T. A. Dickson, head of the firm of T. A. Dickson & Co., florists, Centre Row, Covent Garden. Mr. Dickson was taken ill in August of last year, and subsequently had a paralytic stroke, which, together with general weakness and debility, prevented him from again resuming the active part he had taken in the management of the business, and he passed peacefully away on Tuesday, the 9th inst., in his sixty-fifth year.

The firm of Dickson has been associated with Covent Garden Market for almost a century, and fifty years ago deceased's father had a stand in the market, and a nursery at Brixton. The site of the nursery has long since been built upon, and changes almost as great have taken place in the firm's position in the market. From the "stand" that used to be erected opposite the church, which had to be cleared away every Saturday evening, Messrs. Dickson moved to a position in the Centre Row, and later to the shop nearest to the church, which they at present possess. The business is now purely that of a florist's, and a number of young persons are employed continually in the making up of bouquets and other floral devices. A considerable trade is done in moderate-sized plants of a decorative character, and a group of the flowering plants in season could always be seen outside of the shop. A brother of deceased was, at one time, superintendent of the market previously to Mr. Assbee.

Mr. T. A. Dickson had been employed in the market from his youth. His wife, who was also engaged in the business, pre-deceased him, and he leaves one son. The business, we are informed, will be carried on, as usual, and under the same name, by Mr. F. S. Lucy, a nephew of the deceased gentleman.

Deceased was greatly respected by all frequenters to the market, and his unobtrusive and kindly personality will be much missed. He at one time was a member of the Board of Works, and was also much interested in the Covent Garden Lodge of Freemasons, and in various horticultural charities. For ourselves, we have been indebted to him for valuable information respecting market prices from week to week. The funeral will take place at Norwood Cemetery on Saturday, at 12 noon.

The late MALCOLM DUNN, V.M.H.

THE PANSY.

Its Names and Its Evolution.—Though the Pansy is deservedly admired at the present day, it is open to question if we now regard it with the same affection as did our forefathers. The names they have left us—some thirty in number—are, for the most part, indicative of a deep-rooted sentiment. To explain some of these names, much ingenuity has been exercised during the last hundred and fifty years. Dr. Johnson provides an instance of an extreme nature. In his *Dictionary*, Pansy is explained as a corruption of Panacey (Opopanax); while in his edition of *Shakespeare*, he declares the word "is for thoughts, because of its name Pensées." In this case we may perhaps question the great lexicographer's ingenuity, but not his learning. It is perhaps not so well known that Pansy was at one time a designation applied not to the whole plant, but to the flowers only. In a description of the plant, Dodoens says:—"The French call the flowers 'pensées.'" The Belgians and the people of Brabant employed the word in the same sense. Pansy as a name was not in common use until the present century was well advanced;

it appears sometimes as the Garden Violet, but more commonly as Heartsease. So late as 1840, long lists of varieties, as well as cultural remarks, were published under this title. Sometimes Heartsease alone was employed, though very frequently "or Pansies" was added—as, for example, in Carter's Catalogue for 1844.

"Love-in-Idleness" has been long obsolete. The experience of Lucentio points to a belief that the flower was as potent as a love-philtre in producing the "grand" passion. Shakespeare calls it also "Cupid's Flower." It is mentioned in the same sense by Spenser, and Milton names the Pansy as one of the flowers that formed the couch of the first happy pair. "Cuddle me to you," and many other expressive names bespeak affection. "Flamy" carries us back to the time when Viola flammea was recognised as one of its botanical appellations. Phillip's *World of Words* (1720) has "Flammula, Herb Trinity, or Heartsease." A century later another Phillips says it received the name of "Flamy, because its colours are seen in the flame of wood" (!).

Banwort or Bonewort appears in *The Plant Lore* of Shakspeare as a name of the Pansy and Daisy. Banwyrt in one of Douglas' Prologues is Ranunculus bulbosus, which Markham declares is "venimous for the beast." The Banewort of Lyte's *Herbal* is "Speerwort, or Ranunculus Flammula," which is there said to kill sheep. Yet another Banwort is Atropa Belladonna.

The Pansy found a place in medicine, and was employed to "conglutinate blood" for falling sickness and some other illnesses. In cookery it found no place, but both on the continent and in England it was an early introduction to the "Garden of Pleasure." So little, however, has been said of its qualities by old writers, that we may skip those previous to Miller. He states there were many varieties which differ greatly in the size and colour of their flowers. Some of the varieties have very large, beautiful flowers, which have an agreeable odour; others have small flowers, without scent." And, again, "Some of the varieties have the flowers much larger, and others of the size of March Violets; some of them have the two upper petals of a deep yellow colour, with a purple spot in each, the two middle of a paler colour, with a deep yellow spot, and the lower petal of a velvet colour; in others the petals are white with yellow and purple spots; in some the yellow is the most prevailing colour, and in others the purple." The "spots" above mentioned are doubtless blotches, as later growers called them. Miller, and other cultivators, down to about the year 1825, appear to have raised plants solely from seed, though we may note the mention of Pansies of two distinct shades of blue, which occur in a sensibly-written little book called the *Florist's Manual*, by Miss Jackson, in 1827. This lady employed these Pansies for massing in flower-beds. That keen florist, Hogg, of Paddington, does not mention the Pansy in the first edition (1821) of *A Treatise on Florist's Flowers*. In 1822, second edition, "Heartsease" occurs in a list of hardy plants; and in 1833, when a 208-page supplement of the above-named work was published, about seventy varieties are enumerated. In that year, in an article on the cultivation of Pansies, Harrison, then of Wortley, assures his readers that about 200 varieties were cultivated. Blooms grown to the largest possible size measured 2¼ inches deep by 2 inches across the upper petals. The colouring of many of the flowers about this time was most beautiful. One possessed upper petals of a deep violet, with the lower and side-petals yellow, and splashed on the edges with dark green. Another, in form exactly like a Viola, had a lemon ground colour, with a narrow edge of the faintest blue round all the petals. The upper petals of another variety were dark plum-coloured, the whole of the others cream, belted with peacock-green, and below the eye a blotch of dark orange. One of the prettiest appeared in 1840. This variety had a white ground with a rough belting of lavender, upper petals of the same shade, but faintly edged with light-blue; dark blotches cut off the yellow eye from the white ground. From this date the flowers more and more nearly approached the "properties" of the florist. These Show Pansies were long favourite flowers among the humbler class of florists, one of whom, I remember, on account of his proclivities, having received the sobriquet of "Pansy Will." About 1860, John Downie introduced the Fancy Pansy from Belgium. Its progress was much slower than that of the Show Pansy, because many growers would have nothing to do with it. So late indeed as 1873, a writer in *The Gardener* mentions the variety "John Downie" as approaching very nearly the qualities expected in high-class blooms. In another ten years "Fancies" had become first favourites, a position they have maintained not only on account of their greater beauty, but also because of their stronger and more floriferous habit. Fancy Pansies are obtained fairly true from seed, and for ordinary purposes it is perhaps the best method of propagation. Sown in a little heat in the month of February, very strong plants are produced for flowering in late summer and autumn. *R. P. Brotherston.*

MARKETS.

COVENT GARDEN, MAY 11.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Potatos.

Bruce, Saxon, and Main Crop, 80s. to 100s.; Up-to-Date, 100s. to 105s.; Dunbar Main Crop, 105s. to 110s. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

Remarks.—Jersey new Potatos are now coming in, but there is only a light supply at present. Gooseberries are not very plentiful at present. Foreign Cherries and Apricots are yet of medium quality. There is much variety in Asparagus, home-grown samples are not large. Some of the Australian Pears are very poor. Home-grown Radishes are good.

SEEDS.

London: *May* 10.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that, although the spring Clover-seed season is now about over, a few sowing orders still drop in, which are executed at the low rates current. There is no change in Tares. Full prices are asked for Mustard and Rapeseed. Hemp-seed, on account of its real scarcity, and some resultant speculation therein, is again dearer. For Canary-seed, there is also an improved feeling. The late strong rise in Butter Beans, has hardened values of White Runners. Peas, Haricots, and Lentils also tend upwards. The Linseed market is steady.

FRUIT AND VEGETABLES.

Glasgow: *May* 10.—The following are the averages of the prices recorded since our last report:—Apples, Canadian Spies, 14*s.* to 18*s.* per barrel; Boston States Russets, 18*s.* to 20*s.* do.; Oranges, 4*d.* to 8*d.* per dozen; Tomatos, Guernsey, 4*d.* to 8*d.* per lb.; do., Scotch, 6*d.* to 8*d.* do.; Grapes, home, 2*s.* to 4*s.* 6*d.* per lb.; do. foreign, 6*d.* do.; Spring Cabbages, 10*d.* to 1*s.* per dozen; Broccoli, Edinburgh, 2*s.* to 2*s.* 6*d.* per dozen; Herbs, assorted, 1*d.* to 2*d.* per bunch; Leeks, 1*s.* 6*d.* to 3*s.* 6*d.* per dozen bunches; Mint, green, 6*d.* per bunch; Onions, 4*s.* to 5*s.* per cwt.; Parsley, 3*s.* to 4*s.* per stone; Carrots, new, round, 1*s.* per bunch; do., 5*s.* to 7*s.* per cwt.; Cucumbers, 4*d.* to 6*d.* each; Lettuces, round, 1*s.* 6*d.* per dozen; Radishes, English, long, 1*s.* 6*d.* per dozen bunches; Horseradish, 1*s.* 9*d.* to 2*s.* per bundle; Radishes, round, 6*d.* to 9*d.* per dozen bunches; Mushrooms, 1*s.* to 1*s.* 2*d.* per lb.; Beetroots, 6*d.* to 7*d.* per dozen; Mustard and Cress, 3*d.* per punnet; Spinach, 4*s.* to 6*s.* per stone; Rhubarb, 14*s.* to 16*s.* per cwt.; Turnips, new French white, 1*s.* to 1*s.* 3*d.* per bunch; Swedes, 2*s.* to 2*s.* 6*d.* per bag; Broccoli, Irish, 2*s.* to 2*s.* 6*d.* per dozen; Greens, 5*s.* to 6*s.* for ten dozen; Seakale, 1*s.* to 1*s.* 6*d.* per bunch.

Liverpool: *May* 10. — *Wholesale Vegetable Market.* — *St. John's.*—Potatos, 1*s.* per peck, Peas, 6*d.* per pound; Cucumbers, 4*d.* to 6*d.* each; Grapes, home, 3*s.* to 4*s.* per pound; Pines, English, 4*s.* to 6*s.* each; Mushrooms, 1*s.* 4*d.* per pound. *Birkenhead.*—Potatos, 1*s.* to 1*s.* 4*d.* per peck; do., new, 2*d.* to 5*d.* per pound; Peas, 6*d.* do.; Asparagus, 2*s.* to 3*s.* per 100; Cucumbers, 2*d.* to 6*d.* each; Strawberries, 4*s.* per pound; Cherries, 8*d.* do.; Grapes, English, 1*s.* 6*d.* to 3*s.* 6*d.* do.; Mushrooms, 1*s.* to 1*s.* 6*d.* do.

CORN.

Average Prices of British Corn (per imperial qr.), for the week ending May 6, and for the corresponding period of 1897, together with the difference in the quotations. These figures are based on the Official Weekly Return :—

Description.	1898.		1899.		Difference.	
	s.	d.	s.	d.	s.	d.

The districts indicated by number in the first column are the following :—

0, Scotland, N. *Principal Wheat-producing Districts*—1, Scotland, E. ; 2, England, N.E. ; 3, England, E. ; 4, Midland Counties ; 5, England, including London, S. *Principal Grazing, &c., Districts*—6, Scotland, W. ; 7, England, N.W. ; 8, England, S.W. ; 9, Ireland, N. ; 10, Ireland, S. ; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 6, is furnished from the Meteorological Office :—

"The *weather* was rather unsettled at the commencement of the week, with occasional rain at most of our more northern and north-western stations. After Tuesday, however, very dry conditions, with fine bright days and cold nights, set in over the whole Kingdom, and continued throughout the rest of the period.

"The *temperature* was just equal to the mean in 'Ireland, S.' and the 'Channel Islands,' but below it elsewhere, the deficit ranging from 1° in 'England, S.W.' and 'Ireland, N.,' to 4° in 'England, N.E. and E.,' and 'Scotland, N. and W.,' and to as much as 6° in 'Scotland, E.' The highest of the maxima were registered either during the middle or end of the period, and ranged from 67° in 'England, S.,' 66° in 'England, S.W.,' and 64° in Ireland, to 57° in 'England, N.W.,' and to 52° in 'England, N.E.' The absolute minima, which occurred during the latter half of the week, were very low for the time of year. In 'Scotland, N. and E.' the thermometer in the screen fell to 25°, in 'Scotland, W.' to 27°, and in 'England, N.E.' and the 'Midland Counties' to 28°, while elsewhere the minima varied from 29° in 'England, E.,' to 33° in 'England, S.,' and to 43° in the 'Channel Islands.' The diurnal range was, therefore, large, and sharp ground-frost prevailed almost nightly, the lowest grass readings reported being 22° at Fort William, and 23° at Ochtertyre and Loughborough.

"The *rainfall* exceeded the mean in 'England, N.E.,' and just equalled it in 'Scotland, W.,' but was much less than the normal elsewhere. Over the southern half of the Kingdom [illegible] was hardly appreciable, and many stations were [illegible]hout rain.

"The *bright sunshine* was in excess in all districts. The percentage of the possible amount of duration ranged from 58 in 'England, N.W.,' and 57 in 'England, E.' and the 'Channel Islands,' to 39 in 'Scotland, E.,' and 38 in 'England, N.E.'

Answers to Correspondents

Carnations Diseased : *A. P. F.* The mouldy dirty appearance of the foliage, and the rotten stems, are due to fungi. The plants are being kept too damp. Useful hints on treatment of Carnations will be found in a recent report to the Royal Horticultural Society, Scientific Committee, see *Gardeners' Chronicle*, April 29, p. 270. The disease on your plants is not clearly bacteriosis, yet the fungus present is greatly favoured by excessive moisture. To check the fungus use some fungicide, for example, potassium sulphide at rate of ¾ ounce to each gallon of water ; apply as a fine spray above and below the foliage at intervals of two or three weeks.

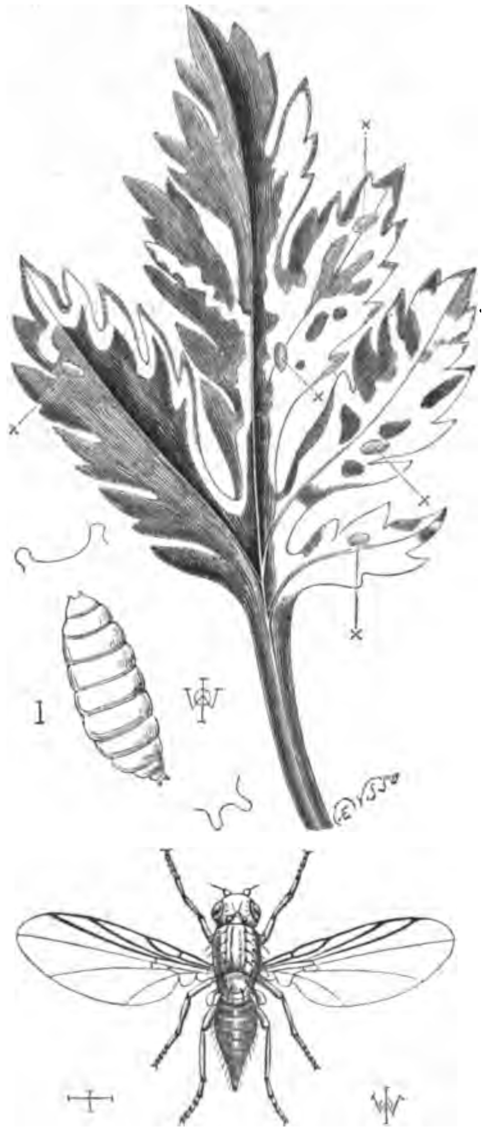

Fig. 113.—The Marguerite Leaf-miner (Phytomyza nigricornis).
[The instances of maggots in the above leaf are indicated by a ×.]

Cucumbers turning Yellow at the Tip : *A. C.* This may be due to several causes, viz., to lack of top or of bottom heat, to disease of fungoid nature, or to eelworms at the root, these being introduced with the soil. Please send some fruits, roots, foliage, &c., for our inspection.

Cytisus scoparius Sport : *E. S.* The plants sent, that have come up in a bed of Cytisus scoparius are identical with C. s. Andreanus.

Dendrobium Jenkinsii : *Veritas.* Dendrobium Jenkinsii usually flowers from the last-matured pseudo-bulbs, although any of the older bulbs may produce flowers from the unflowered nodes.

Fish Manure : *R. B.* Yes ; use in the proportion of one part manure to sixteen parts compost.

Fruit by the "S.S. Omrah" from Tasmania : *J. Barnard, Bowes Park.* The vessel was expected in the river on Thursday last, *i.e.*, a day and half before the advertised time. The major part of the cargo will go to Covent Garden, and be there disposed of by auction. It is usual for samples of the fruit brought over from Australian ports to London to be exposed at a few shops in Monument Yard one day before sale takes place, and announcements of sales are made in the same quarter.

Insects : *Windsor.* The beetles are Aphodius fossor ; very common at times in cow-dung and manure. Not in any way injurious, that we are aware of.—*B. L. H.* In respect to the woodlice, you must catch them. Hollowed pieces of Potato, Turnip, &c., turned with hollowed side downwards, make very good traps ; and if looked at occasionally, and those insects found secreted thereon plunged into boiling water, you will soon diminish their number.

Marguerite Leaves : *South Walian.* The leaves are attacked by the Marguerite Leaf-miner (Phytomyza nigricornis), see figure, which we reproduce below. The maggots of this insect eat all the fleshy portion of the leaf, leaving the two surfaces entire. It will be best to remove every badly-infested leaf from the plants, and burn them. Go over the plants occasionally afterwards, and by examining leaves still affected, the maggots can be detected, and squeezed between the thumb and finger.

Melon Leaves Diseased : *Constant Reader* and *F. L.* This is an "anthracnose," due to a fungus. Melons and allied plants are attacked by various fungi which produce spotting of the leaves. The same is the case abroad, and much attention has been given to diseases of this kind in America, where they are very prevalent. A good remedy has yet to be found. The kind of fungus present indicates too much moisture and lack of air ; the plants would be stronger and the fungus checked if this were adjusted better. With regard to spraying, the best we can do is to quote an American of much experience. He says, "Cucumbers, &c., may be treated with fungicides for anthracnose and mildew with reasonable hope of success. Bordeaux Mixture was the best substance employed in my experiments, it not only increased the yield, but prevented rotting of the fruit."

Names of Plants : *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*B. A. C.* 1, Dendrobium pulchellum ; 2, Cypripedium Lawrenceanum ; 3, Adiantum hispidulum tenellum ; 4, Selaginella viticulosa ; 5, Berberis stenophylla ; 6, Kerria japonica flore pleno.—*S. G. S.* Begonia incarnata maculosa ; 2, Selaginella viticulosa ; 3, Adiantum cuneatum mundulum ; 4, Pitcairnea angustifolia ; 5, Cissus discolor ; 6, Begonia nitida, probably, send when in flower.—*F. M.* Oncidium luridum ; 2, Oncidium altissimum ; 3, Oncidium sphacelatum.—*M. G.* 1, known in gardens as Chlorophytum Sternbergianum ; 2, Tracheleospermum jasminoides ; 3, Centaurea ragusina ; 4, probably Libonia penrhosiense, send when in flower.—*R. E. C.* Ornithogalum nutans, and may be found wild in many places.—*F. G. S.* Vitis antarctica, known in some gardens as Cissus antarctica.—*E. S., Durham.* Asclepias curassavica.—*W. T.* Your Odontoglossum is a pretty form of the pink-tinted O. Andersonianum known as O. Ruckerianum. It is not a true O. crispum, but a natural hybrid of it and O. gloriosum.—*F. C.* Too scrappy to be named with certainty.—*G. H.* 1, Anemone hortensis var. stellata ; 2, Exacum affine ; 3, next week.

THE
Gardeners' Chronicle
No. 647.—*SATURDAY, MAY* 20, 1899.

AN OLD SCOTCH FLORIST.

"ABOUT the beginning of the eighteenth century the best garden in Scotland was that of J. Justice, at Crichton, near Edinburgh." So wrote Loudon; but he was scarcely correct. Because the fame of this celebrated garden was unknown till the thirties, and it was not until towards the end of his career, perhaps twenty years later, that the reputation of the garden was at its highest pitch. As in the case of Shenstone, the love of Justice for gardening was carried to such extreme lengths, that a few years previous to his death (1762) he had to dispose of his property and his collection of plants. His father was a merchant in Edinburgh, and must have been possessed of no little wealth. He, himself, was a lawyer, and held an appointment as one of the principal Clerks of Session, an office held later by Sir Walter Scott. Justice is now most generally known as the pioneer cultivator of the Pine-apple in Scotland, having in 1732 erected a pine-stove in his garden at Crichton, and there commenced its cultivation, which soon spread over the country. A plan of this structure appears in his *Scots' Gardener Director*, and it is obvious that, for the period, it was erected regardless of expense.

The above-named work was first published in 1754, and it was the intention of the author at first that it should have comprised all sections of gardening. He, however, found that it would be inconvenient to do so, and merely divided it into two parts, the first of which, "Practical Instruction in Gardening," is confined to the cultivation of fruit and vegetables, and the second, "Anthology; or a Treatise of the Culture of Flowers, and Practical Instructions given therein, being the result of Experiments in Floristry, from 1726 to 1751." The first part, though it was at one time highly esteemed, is in reality the least interesting, because one feels that much of the matter is largely subject to conjecture on the part of the author. The portion devoted to flowers, on the other hand, is very largely original, and with the lapse of years must become increasingly valuable as a record of successful floriculture in the eighteenth century.

Perhaps, next in time to *The Scots' Director*, the work entitled *The British Gardeners' Calendar*, chiefly adapted to the climate of North Britain, to which is added a Dissertation on Forest Trees, would make its appearance. It was published in 1759. *The British Gardeners' Director* was the last of Justice's effusions, and is largely an extended *Scots' Director*. It appeared in 1764.

Reverting to *The Scots' Director*, one is pleased to find it the repository of exhaustive lists of vegetables and flowers cultivated in Scotland 150 years ago. The 1721 edition of Reid's *Scots' Gardener*, as well as that of 1766, no doubt contains a limited number of flowers, in addition to those named in that of 1683. But compared with the lists in the *Director*, they are limited indeed. It is, however, not a little curious that the Potato, though mentioned by Reid, does not appear in the above. The omission seems to emphasize the early dislike exhibited by the Scots to the noble tuber, the reason for which may have been the same as that of the Puritans, viz., the absence of any mention of the esculent to be found in Scripture!

Vegetables, as detailed in an inserted copy of Patrick Drummond's *Catalogue for* 1754, were numerous and well selected; the gardener, for example, having had to select from: twenty-four sorts of Peas, twelve sorts of Lettuces, eight kinds of Kidney Beans, ten sorts of Cabbages, not including Savoys and Kales.

The "Pot-herbs" include Columbine, Virginian Tobacco, cultivated as a vulnerary; White Poppy, and Carduus Benedictus, the last esteemed as a febrifuge. Evelyn mentions how he sat covered with blankets, his legs in a "deepe churne filled with hot milk, and drinking carduus posset, then going to bed and sweating." It worked a cure!

In the lists of hardy fruits, we find in addition to many French and English Apples, such decidedly Scotch varieties as the Grey, Yellow, and Stoup Leedingtons, Fulwood, Gogar Pippin, Potteraw Apple, and the French "Orgillon," generally thought to be Scotch under the names of Oslin and Arbroath Pippin. Among Pears are Achan, Swan's Egg, Crawfurd, Golden Knapp, Carnocks, and Lemon Pear. Plums include "Hairsflaws," a name I have nowhere seen but here. We gather from the text that hardy fruits were cultivated almost entirely in "Orchyards," which Justice recommends doing away with, and instead, growing Apples, Pears, and Plums on dwarfing-stocks, as espaliers in kitchen gardens. "Currans" are recommended to be trained upon walls on north aspects; and the finer Apples—Golden Pippin, Nonpareil, and Reinette Gris—on walls for dessert.

It was, however, as a cultivator of flowers, and particularly as an expert in bulb-culture, that Justice excelled. He appears to have cultivated what in his judgment were the most beautiful of all kinds of flowering bulbs, and in order to thoroughly understand continental methods of culture, he made two voyages to Holland and Flanders, and also travelled through Italy. The result of his observations was the adoption of Dutch methods, modified to suit the climate of Scotland. Success, as he informs us, beyond that achieved by foreign growers, attended his efforts, and instead of imported bulbs dwindling in size as was usual, they increased from year to year, and produced better spikes than he had ever elsewhere seen. The soil he employed for Hyacinths was largely composed of dung, or, in his own words, of "four shares of old, well-rotted cow's dung, one share of pure white sand, and one share of peat."

In his opinion the soil near Leith was eminently suited to produce bulbs of the best quality, and he strongly advised florists to undertake their propagation and growth in that locality. The method of growing Hyacinths from offsets is fully detailed, and that of raising new varieties from seeds. The best kinds to grow for seeding are also named, which were all semi-doubles, though Hill (*Eden*, 1759) recommends a single variety called Zumbul for this purpose. Justice was fully convinced, as the results of his own observation and experiments, that new varieties could be originated in Scotland, and old varieties multiplied as successfully as in Holland, and the necessity of annually purchasing from the foreigner a supply of flowering roots of Hyacinths, Tulips, and Narcissus obviated. But it cannot be concealed that a Hyacinth in 1754, was a different flower from that of to-day. The finest spike he was ever able to produce was composed of thirty-eight bells, and he considered that number extraordinary. Varieties engraved in Hill's *Eden* had only a few bells on each, and as late as 1807 a plate by Sydenham Edwards of a group of Hyacinths, shows that the advance had been inconsiderable at that date. Raising good seedlings, it will therefore appear, was not so very difficult.

In addition to a long list of named varieties set down without remark, there is also a descriptive list of the best single and double varieties in the collections of the celebrated firms of Voorhelms and Van Zompell. Of single varieties sixty-two sorts are thus described, and of double kinds eighty-six. The finest of the former was La Reine des Femmes, which produced, at Crichton, thirty-four to thirty-eight bells, and was sold when new at 50 guilders a root, "which is a great price for a single Hyacinth." From Hermaphrodite, a semi-double variety, he "raised some very valuable double flowers." Justice entertained no doubts as to which, single or double, were best worth growing. The former were esteemed for growing in "Water-glasses," but the latter were in a particular manner the flowers of the florist. Gerard mentions both double and single sorts, and there is, therefore, good reason for thinking doubles to have been the chief sorts cultivated for the better part of three centuries. The money-value of double sorts will appear from the following quotation, while it also displays the descriptive powers of our author:—

"Konig Solomon is one of the grandest and prettiest flowers which has ever appeared amongst the Hyacinth tribes, and it may well be named King Solomon, as it may justly vie with that great Prince in the prime of all his glory. This hath a high and bold strong stem, adorned with a great Number of vast, large, strong, succulent, spicy-smelled, erect, and admirably well-reflected Bells, which attract the Eyes, and inspire Joy to the Beholder, and display a large Heart most admirably enamelled with carnation, white, yellow, and bright green Colours, it has a noble Spike, and is a late Blower; at its first appearance it was sold for 600 Gilders per Root." That is, £51 5*s.*; Gloria Mundi sold for 500 guilders, but common sorts were inexpensive.

He also cultivated a large collection of Tulips, in which "Semper Augustus" of Tulipomania fame appears. For want of time he did not attempt to raise seedling Tulips. One of his favourite flowers was Polyanthus Narcissus, among which appear among others the names of Soleil d'Or and Bazelman Major, sorts still in commerce. He notes these as being well suited for water-glass culture. Ranunculus and Anemones were planted not only in the open ground but also in pots. These were cultivated with great zest at the period under review, and Justice introduced numbers of seedlings. His collection of these and some other plants seem to have passed into the hands of Anderson & White, nurserymen, whose collection of Anemones in 1766 was said to be the finest in Britain. Fritillarias, Irises, and Liliums were also largely grown by Justice. His collection of Primroses, and in particular of the Polyanthus Primrose, was large. Of the latter he sowed the seeds in boxes of soil in June, planted out the following March, and when the plants flowered, he selected the best, and preserved them only. He remarks, "Some incomparable beauties happen often to reward the trouble of sowing and cultivating them." His collection was considered superior to any in Great Britain.

For Auriculas also, Justice was deservedly famous. The seed of Scotch Auriculas was said at this period to have been exported to Holland, and its produce imported to England. At this time the quality of the individual flowers was not so much considered as size of truss. Justice allowed two trusses to remain and develop on his blooming plants. He raised seedlings from seed sown directly it was ripened and gathered. He cultivated a few plants in the open ground, and potted them up to flower. Frames, provided with wooden shelves rising in tiers were used to exhibit the plants when in bloom, and a portion of the collection was cultivated in frames facing north.

In addition to the flowers already mentioned, other 400 sorts are more or less fully described and culturally treated. For seven years he tried to raise the double white Hepatica from seed, but failed, "although," he says, "I raised many singles and semi-doubles of various whites, flesh, and carnation colours; and will try again for it, for I am told the florists in Holland have obtained it from seeds." The double white Hepatica is one of the mysteries of floriculture, it having been recorded as existing by many old authors, while others altogether deprecate its having ever had an existence. With the Sweet William he had a more gratifying experience, for as he relates:—"In Anno 1749 I raised in my garden a plant of the whole-podded double Sweet William, of a colour finer than Fairchild's Mule. These plants put into pots in a light fresh soil, make a pretty appearance in the windows or chimnies of rooms in summer." His remarks on Carnations are very good, and these he preferred to grow in pots, because "it makes a better show to blow them in pots, and upon a proper stage, than in the open ground." From which it will appear that our author was before everything a florist. *R. P. Brotherston.*

THE BULB GARDEN.

CRINUM LATIFOLIUM.

THIS magnificent Crinum is just now in flower. It has a flattened bulb, 8 inches in diameter, and a dozen tapering, channeled leaves, each 3 feet long, and 6 inches wide at the base. The peduncle is 3 feet high, and now bears an umbel of a dozen almost sessile, fragrant flowers, each 10 inches long, and consisting of a green, curved tube, and a horizontal, cupped limb of equal length. The perianth segments vary in width from 1 to 2 inches, are recurved at the tips, and have a pale band of red on the outside, a very slight tint of this colour being suffused throughout the whole flower. The plant delights in an open, rich, and durable soil, plenty of water, and a temperature during growth of 60° F. The leaves being deciduous, the plant may be rested in a temperature of 45° F., and the bulbs require but little or no water until the following spring. C. latifolium is an Asiatic species, and is in no respect difficult to cultivate. By shading the plants from strong sunshine they may be grown out-of-doors during the summer months.

HIPPEASTRUM ORGANENSE.

Like many other species of Hippeastrum, H. anense (*Bot. Mag.*, t. 3803), has been crowded from most gardens by the showy cross-bred varieties. An example is now flowering here, from an importation of last year, described by the importer as having been found growing "in a sub-epiphytal state on the bifurcated trunks of forest trees in Brazil." It is characterised by having acute leaves, 1½ foot long; a peduncle as long as the leaves, bearing two flowers with short green tubes. The perianth segments are undulating, thin, and satiny, light crimson above, bright green below, and are united at the base by an ivory-white incurved corona. The plant requires an open, rather loose compost, as the roots ascend if they meet with much obstruction. The temperature and shading usually given to Cattleyas suits this plant.

ELISENA LONGIPETALA.

This beautiful and rare bulbous plant produces lorate, distichous leaves, a yard or more long, and a flattened peduncle, 4 feet high, bearing seven pure white flowers, each with a spreading limb, 9 inches in diameter, the segments being narrow, undulating, recurved, and much twisted. The stamens and styles are very conspicuous, and recurve at the tips. The plant requires a temperature of 55° F., when growing, with plenty of water, and shade from strong sunshine. The bulbs may be dried off gradually when growth has ceased, and the leaves begin to turn yellow, withholding water altogether from the beginning of the following winter until growth recommences. E. longipetala may be propagated by offsets or by seed, both of which it produces very sparingly. The plant grows well in a light sandy loam, enriched with leaf-soil, and if healthy, it should not be disturbed for several years. The plant was figured in the *Bot. Mag.*, t. 3873. *G. B. M., Isleworth.*

KEW NOTES.

MARANTA MAJOR, *hort.*—When a market-grower gets hold of a useful decorative-plant that is new to him, he gives it a name which fits it more or less, and serves his purpose. This is what happened to the plant known in gardens as Maranta major, which has been grown by London nurserymen for at least six years, finding a ready sale for furnishing purposes. It is described as a Maranta of pleasing aspect and graceful habit, with tufted leaves 2 to 3 feet high, composed of slender brown petioles, and an oval blade 4 to 9 inches long, of different shades of green. It has the constitution of an Aspidistra, enduring for a long time without injury the dry atmosphere and changing temperature of the dwelling-house. This plant has been grown at Kew for the last twenty years at least, and its correct name is Ischnosiphon leucophœus. The genus Ischnosiphon is closely related to Maranta, and consists of over a dozen species of tall green-leaved plants, with long, slender branching spikes of sheathing bracts, and small uninteresting flowers. All the species are natives of tropical America, I. leucophœus being Brazilian.

DIANTHERA ILLUSTRIS.

Plants of this pretty Acanthad, also called Porphyrocoma lanceolata, were exhibited under the first-mentioned name by Messrs. F. Sander & Co. at the meeting of the Royal Horticultural Society held on April 18. Although an old garden-plant, it puzzled the Floral Committee, and it was only on examples of it being forwarded to Kew, that it was identified with the plant figured in the *Botanical Magazine*, t. 4176 (1845). It is there described as "a truly charming plant, for the possession of which we are indebted to Mr. Forkel, gardener to His Majesty the King of the Belgians, at Brussels, who sent it to us under the above name; but, unfortunately, without any history, so as to leave us in the dark as to its native country, or the author of its very appropriate name (*porphyros*, purple; and *kome*, head of hair), given in allusion to the singularly richly-coloured spikes of deep purple, from within the scales of which the scarcely less brightly-coloured bluish flowers appear. It was exhibited in the Horticultural Society's Rooms, and excited admiration from the beauty of the blossoms, which consist in the dark purple comb-like parts, half covering the Lamium-like violet flowers." It grows to about a foot in height, and has drooping lanceolate dark-green leaves. It has been called Amphiscopia Pohliana, and is now known to be a native of Brazil.

RICHARDIA SUFFUSA.

Except for the absence of grey spots from the leaves, and the larger size of the spathe, I do not see how the plant exhibited at the Drill Hall last week under the first-mentioned name differs from R. melanoleuca, figured in the *Botanical Magazine*, t. 5765 (1869). This species is remarkable for its wide, almost heart-shaped leaf-blade, the presence of bristle-like hairs on the base of the leaf-stalk, the comparative shallowness of the spathe, which is cream-yellow, and open to the very base, thus exposing the large irregular blotch of dark purple at the base, and the short, erect spadix. It was first introduced by Mr. William Bull, and flowered in his Chelsea nursery in 1868. The absence of spots on the leaves of the plant shown last week is not of much significance, as everyone acquainted with the plants of this genus knows. Thus, there are green and spotted forms of R. Pentlandi and R. Elliotiana; and I have seen a green-leaved R. Rehmanni. R. aurata, of which a flower was shown for comparison with the plant called suffusa, is a form of R. hastata, which has very different leaves from R. melanoleuca. *W. W.*

THE ROCK GARDEN.

THE ROCK GARDEN AT LITTLE SILVER, HIGH BICKINGTON, NORTH DEVON.

THE accompanying illustrations depict a portion of a rock-garden which—on behalf of Messrs. R. Veitch & Son, Exeter—I had the pleasure of constructing about four years ago. Little Silver, the property of Captain Barton, is situated on a very conspicuous hill among picturesque surroundings, within a dozen miles of Barnstaple. The approach is by means of a rather steep carriage-drive, traversing a wood, but the summit of the hill on which the house stands is only scantily planted with trees, and affords therefore admirable views over many miles of the charming valley of the river Taw, which latter can be distinctly seen meandering through meadows, rocks, and woodland.

In laying out the grounds, the abrupt slope near the house was rather difficult to deal with. An ordinary terrace-slope among natural surroundings so bold and excessively undulating would have been quite out of place, and for this reason, chiefly, it was suggested that the grounds adjoining the house should be supported by apparently natural rock, which would not only harmonise better with the surrounding country but furnish an excellent home for alpine plants. A quarry of suitable stone was among the resources of the estate, from which it was an easy matter to procure suitable materials, consisting of stratified layers of hard shale, with veins of chert and ironstone.

A slope in front of the house was unavoidable, but it was made of a character as bold and undulating as possible, and varied here and there by rocks occurring singly or in scattered masses, having the appearance of having been forced through the sward by volcanic agency. In the steepest and boldest portion of this slope the rocks, too, were made to appear more imposing and more massive in character; and the first illustration (fig. 114) gives an idea of a small cave in this part of the work. This, especially on a hot summer day, forms a cosy retreat, with room to accommodate about half-a-dozen persons, its coolness being added to by a purling stream that issues from one of its recesses, which, after disappearing below the floor of the cave, forms a small pond as seen in the foreground of the illustration. The cave is so arranged as not to be dark in any part, and the large stones forming the roof are at some little distance from the back wall, and admit sufficient light to enable all kinds of Ferns, some species of Primula, and groups of Ramondia pyrenaica to flourish at the back of the cave. There, too, Adiantum pedatum expands its arching fronds to much advantage, and mossy Saxifrages help to enliven the scene.

The pond referred to had, of course, to be formed with cement, but of this every trace was carefully concealed, partly by groups of rocks, and partly by the sward dipping down to the level of the water. The aquatics visible in the picture are Aponogeton distachyon and Menyanthes trifoliata. But besides these a number of choice Water Lilies were planted in spaces specially prepared for them, and these afford excellent effects. Among the smaller species used are Nymphæa Laydeckeri rosea, N. pygmæa alba, and the pale yellow-flowered N. pygmæa helvola. The larger growing species of Water Lilies are N. Marliacea carnea, N. M. chromatella, and N. M. albida. The overflow from the pond forms a streamlet that loses itself beneath a rock. From the grassy banks bordering the pond and streamlet, spring colonies of moisture-loving plants, so arranged in this instance that the roots have easy access to the water. Among such plants, I may mention groups of German Iris and Iris Kæmpferi, the dark rose-coloured Lythrum Salicaria var. roseum superbum, Spiræa rivularis, S. astilboides, the tall and bold S. gigantea, S. palmata, Osmunda regalis, Carex pendula, C. regina, several forms of Hemerocallis, besides other moisture-loving plants.

The portion of the rock-garden immediately above the cave shows, in the second illustration (fig. 115), the exterior roof of the cave as seen from above. It also shows how in parts the rocks, for the sake of variety, have been interspersed with grassy banks, studded with suitable plants. In the foreground are batches of Genista scoparia var. Andreana, Fuchsia pumila, and Iceland Poppies in variety.

Towards the middle of the picture are seen the handsome corymbs of Anacampseros Borderi, whose fleshy leaves and red flowers remind one of Sedum macrophyllum; and here are also bright masses of Armeria maritima rosea, bright blue flowering Campanulas, the pink Acantholimon glumaceum, and several colonies of Megasea purpurea, which, with its large leathery leaves and rosy-purple flowers, is particularly striking in appearance. Other bold plants used are Yuccas, the graceful Hedysarum multijugum, Centaurea montana, in pink, white, and blue varieties, and a collection of Helianthemum in variety. This illustration also shows rocky steps leading from the cave and the lower portion of the ground to the higher level near the house. The steps have been adorned with species of Thyme, with Arenaria balearica, A. cæspitosa, Herniaria glabra, and other plants of prostrate habit, which in time will partly conceal them, and thus afford a natural appearance.

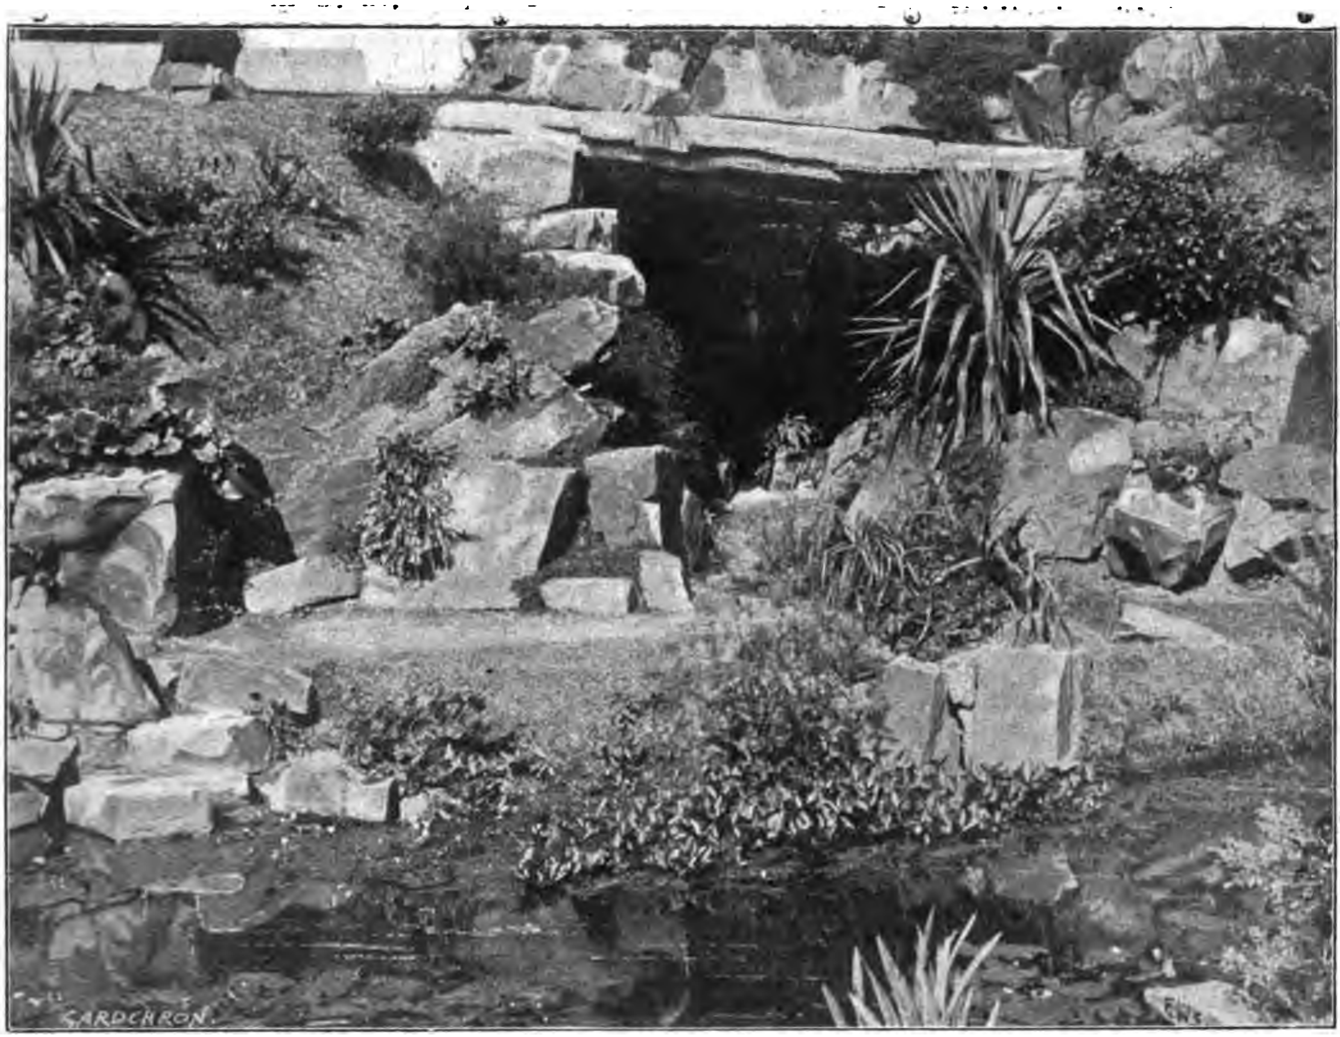

FIG. 114.—CAVE IN THE ROCK-GARDEN AT LITTLE SILVER, HIGH BICKINGTON, SOUTH DEVON. (SEE P. 310.)

(Constructed and photographed by F. W. Meyer.)

The whole rock-garden, from the fact of its being not a continuous mass of stones, but very much broken up by groups of plants or grassy banks, appears very much larger than it is in reality, and as the plants are arranged not so much with a view to immediate effect as to successive display of form and colour, there is always something in bloom.

I cannot go into details about all the plants used, but must be content with enumerating some of the principal ones which have given the best results. Among small plants I will mention Hutchinsia alpina, Primula viscosa, P. nivalis, P. villosa, P. Auricula, P. intermedia, Edelweiss, Saxifraga Burseriana, S. apiculata, S. oppositifolia, S. juniperina, S. sancta, S. longifolia, Potentilla nitida, Veronica telephiifolia, Achillea rupestris, various Gentianas, Sedum spatulifolium, Androsace carnea, A. lanuginosa, and many more. The plants just enumerated are so placed, that they cannot speedily be overrun by others to their injury. Among medium-sized plants of this type, I may mention Carlina acaulis, Dianthus arenarius, Helenium pumilum, Heuchera sanguinea, Campanula glomerata, C. dahurica, Zauschneria californica, Dianthus superbus, Eryngium alpinum, Morina longifolia, Centranthus coccineus, Lysimachia Nummularia, Prunella grandiflora, &c.

Here I may also quote a few of the taller kinds of perennials which were used partly in groups and partly as single specimens, viz., Lychnis chalcedonica, Campanula persicifolia alba, Helenium striatum, Echinops ruthenicus, Tritoma caulescens, Doronicum excelsum, Papaver concolor, Delphinium in variety, and many more.

That numbers of suitable "rock shrubs" were also used goes without saying, and among these were the bright Alpen Rose (Rhododendron ferrugineum), bushes of Cytisus nigricans, Indigofera Dosua, the Tree Ivy, Cotoneaster congesta, Erica codonodes, other species of Erica, and Japanese Maples.

Every part of the rock-garden is easily reached, either by a grass or gravel-path, or by rocky steps, very naturally contrived. For the pond and also for the roof of the cave the use of cement could not be avoided, otherwise no cement or mortar has been used in the construction. Where stones adjoin each other it was thought desirable to fill the crevices with soil and plants rather than with cement or mortar, and many of the choicer Alpines, if planted in suitable soil, succeed in such narrow crevices better than anywhere else.

The whole of the plants are now well established and in a flourishing condition. The illustrations are from photographs which I took last summer. *F. W. Meyer, Elmside, Exeter.*

THE MUSCARI.

(Concluded from p. 292.)

THE *Index Kewensis* enumerates some fifty-seven species. In the Kew *Hand-List of Herbaceous Plants* twenty-six species and varieties are given as being grown in the Royal Gardens, Kew, at the time of its compilation. There is not entire agreement between these two works. In the former M. atlanticum is referred to M. racemosum; while in the *Hand-List* it is kept apart. Similarly, M. macrocarpum is referred to M. moschatum in the *Index*, but in the *Hand-List* it appears as a species. M. Maweanum is not mentioned in the *Index*. M. suaveolens is given in the latter as synonymous with moschatum, but in the *Hand-List* it is a separate species; so is M. transsilvanicum in the *Hand-List*, but in the *Index* it is referred to M. botryoides. Where so much difference exists between these authorities, it is to be expected that the confusion in gardens and nurseries is even greater. One fears we must be content to take the names to some extent as they are. It will thus be found better to speak of the various Muscaris one has grown principally from a gardening point of view, and without committing ourselves to the correctness of the names.

M. botryoides, one of the best of our Grape-Hyacinths, is much less frequently seen than it should be; and one is surprised to find that in many districts it is not nearly so common as the considerably duller M. racemosum. M. botryoides, the sky-blue Grape-Hyacinth, is a lovely little flower, with charming bright blue flowers, with whitish margins round the orifices. Few flowers are brighter in their time than this Muscari. The flowers are arranged in a long cluster, which reaches from 6 to 12 inches above the soil. The linear and channelled leaves are erect. It comes from Southern Europe, and may well be the one spoken of by Ruskin in the words already quoted. There is a very beautiful pale blue variety named M. b. pallidum, which has long spikes of pretty flowers; a superior form of this is named grandiflorum. There are two or more white varieties. One sometimes passes under the name of M. b. album compactum. This has very small flowers, closely set in a small, short cluster, and is inferior in beauty to that known as M. b. album grandiflorum. This has larger blooms and longer spikes. There is a variety named M. b. carneum, which has whitish flowers, faintly tinged with flesh-colour. Eventually from this we may obtain the coveted red variety, unless it is obtained from the blue form. M. botryoides has the fault of increasing too rapidly.

M. Heldreichi, the Greek Grape-Hyacinth, is an exquisite little flower. It is not always obtainable true to name, but I have had it both by way of Italy and Holland. It is said by some that it is later than M. botryoides, but the contrary is the case with me. Here it is the first of the true Muscaris to bloom; it is lighter in colour than the typical M. botryoides, with more of white on the flower and having larger blooms. M. Heldreichi increases freely at the root, but I have not had any seedlings, so far as I have seen, in the number of years it has been in my garden; it grows to 9 inches high in light soil.

The old M. racemosum looks dull and ineffective when compared with the foregoing, its deep blue flowers, which have what is described as "the odour of plums," being dull and wanting in brightness. They are smaller also, and in a close cluster. The leaves are spreading and nearly prostrate. Very pleasing is M. r. carneum with pink blooms. M. neglectum is closely connected with M. racemosum, but is, in the writer's opinion, more handsome with its sweet-scented long raceme of deep blue flowers. One finds these two do duty for each other in some bulb-gardens. M. commutatum, a Sicilian species, has blue flowers which pass off to purple; it is very pleasing in some of its stages with its many-flowered racemes. M. suaveolens, or what I have had for it, was not unlike M. neglectum, but with a stronger perfume.

My first acquaintance with M. atlanticum was made in the Edinburgh Botanic Gardens many years ago, but it was some time before I had it. It is of a dark, not yet dull, blue, and has a fine, compact raceme of flowers. I should hardly class it—or at least the plant I have for it—with M. racemosum. I appear to have lost M. armeniacum in the course of some garden alterations; I know that I had it, but it has now disappeared. It is a lovely little Muscari, with fragrant flowers of bright dark blue, with three yellow spots near the mouth.

M. Szovitsianum is a very beautiful little Muscari, with small flowers on a short raceme. The flowers are of a light blue, of a shade near, but not the same as, that of Heldreichi. It is of dwarf habit, and comes into bloom rather early. M. conicum is a lovely species, said, in the *Dictionary of Gardening*, to come from the Campagna; but, according to the *Kew Hand-List*, its habitat is "uncertain." Wherever it comes from, it is one of the finest of our Grape-Hyacinths. It has been called "Heavenly Blue" by one of our nurserymen, and there is some excuse for the name, although it strongly resembles some of those given to flowers by pushful nurserymen among our kinsfolk across the Atlantic. Under the name of M. Pinardi, I had from a continental nursery a Muscari which, despite its glowing description, had no particular merit.

When seen in a mass, M. Maweanum is pretty, but where there is so much resemblance among members of the genus that it is hardly worth having by those persons who desire flowers showing some distinctness. M. Argaei, as I have had it, appears to be the same as M. atlanticum, but I think it should have smaller flowers, and a shorter raceme. M. polyanthum, which is well spoken of, is here, but it is flowering for the first time this year, and is not, at the time of writing, so far advanced as to enable me to speak with any confidence.

M. pallens I do not much care much for. It is not pure enough to be called white, nor sufficiently coloured to be pearl-blue. The racemes are comparatively few-flowered; it comes from the Caucasus and the Crimea. From Broussa I received what appears to be M. pallens, under the collector's name of M. racemosum album. What I have as M. Strangwaisii is a pretty little flower with sharpish racemes, and of free-blooming habit. Among those of this section of Muscaris whose acquaintance I have yet to make are M. Lelievrii, M. latifolium, and a few more or less doubtful species. Muscari comosum is more appreciated as a curiosity than for its beauty; it grows very vigorously here, and usually causes some surprise among people who see it for the first time, although their remark of "queer-looking" is not very flattering to its appearance. In a continental catalogue one finds a considerable number of varieties of M. comosum offered. Acquaintance with the type does not induce me to add these to my garden flowers. It is a singular flower with its tasselled head. Its variety, M. comosum monstrosum, the feathered Hyacinth, is, however, both singular and ornamental, so that it is to be regretted that one sees it so seldom now. Its violet-blue flowers, of slender, frizzled filaments, are quite unique among bulbous plants.

Only for a year or two after purchasing them have I been able to bloom the Muscaris of the type of M. moschatum. The typical M. moschatum is inconspicuous with its greenish-yellow flowers, but the sweetness of their odour is some recompense for the poor colour. Under the name of M. macrocarpum I had a form with brighter flowers, but I have been unable to ascertain whether this was the true M. macrocarpum, or the variety of M. moschatum named flavum. I have compared experience with a number of my friends who have tried the Musk-scented Grape-Hyacinths. Unfortunately they seem no more fortunate in blooming it in successive years than the writer.

I am all too conscious of the shortcomings of this account of the Muscaris. Only those who have tried to work out the genus can appreciate the obstacles in the way of a satisfactory notice. This is, however, presented with the object of endeavouring to draw some attention to a pretty, but neglected, class of plants adapted to the ornament of our gardens. *S. Arnott, Carsethorn, by Dumfries, N.B.*

HATFIELD PRIORY, WITHAM.

PLEASANTLY situated in a beautifully wooded park, 3½ miles southward from Witham, and within 1 mile of the picturesque village of Hatfield Peverel, is Hatfield Priory, the property of C. W. Parker, Esq. The several fine specimens of Cedrus Libani which luxuriate near to and in front of the Priory, go to show the ancient date of the old Priory. This building has been superseded by the present edifice—a square house built in the Georgian style. The huge fan-like branches of the Cedars reach to the lawn, and the trunk of the largest one measures 23 feet in circumference. The grounds opposite the south front of the house slope sharply from the terrace down to the fence dividing them from the park. Here a series of flower-beds on the turf form a pretty design, though they might be thought by some to be somewhat crowded. The view from the flower-garden southward is extensive and diversified, and includes "Little Baddow," a favourite place for pic-nics, a short distance from the river Chelmer. The woodland scenery west of the house is satisfying. A grand shapely specimen of the common Beech stands out boldly by itself to the left, and within about 100 yards of the sheet of water at this side of the Priory. There are also numerous handsome specimens of the Ash, Oak, Elm, Chestnut, Plane, Sycamore, in the park and grounds. At the north side of the house, Mr. Parker converted a border of large overgrown Rhododendrons into veritable trees, furnished with young growth, and thick healthy-looking foliage, from the ground up to a height of between 3 and 4 feet, by skilful pruning. A fine Holly-hedge close by also bears evidence of his ability to convert and shape long-neglected and objectionable tree-growth into objects of beauty. Those who built, or were responsible for the building, of monasteries and priories, have one and all left evidence of their great desire to enclose them with tall hedges and trees, in order to ensure privacy. A large plant of Magnolia grandiflora, trained over a wall on the south-side of the Priory, with its large white flowers and handsome green leaves, was very effective. A nice plant of M. conspicua, similarly trained, appeared to be trying its best to cover the space allotted to it on the wall.

The church stands in the grounds of Hatfield Priory, and a very pretty one it is. The family have an entrance to it from the Priory itself; and on the velvety turf on either side the central walk, some pretty designs are cut, a Maltese cross forming the centre of the figure, that on one side being a facsimile of the design on the other side. These beds at the time of my visit (August 6) were very attractive, being filled with suitable flowering, foliage, and subtropical plants. Beds filled with Black Douglas Pelargoniums, and edged with the silvery-leaved Flower-of-Spring Pelargoniums, showed off to advantage. The Maltese Cross, with Tropæolum Vesuvius, edged with Golden Feather, and patches of blue Lobelia at each end, and "dot" plants of Chamæpeuce diacantha was effective as a bit of bedding-out. Begonias semperflorens was employed with good effect in the composition of these beds. A ribbon border running parallel with the south wall of the church, planted with sub-tropicals, and Calceolaria amplexicaulis in the back row, and Verbenas in the front, were attractive, as were also Clematis Jackmanni, the variegated form of Lonicera flexuosa, and Jasminum officinale, trained up the church wall. A wall formed the boundary of this miniature and neatly-kept flower-garden on the north side, clothed from bottom to top with Euonymus radicans variegatus, which formed a striking contrast to the green, closely-cut grass and the various shades of colour in the foliage and flowering plants which occupied the bed in the foreground.

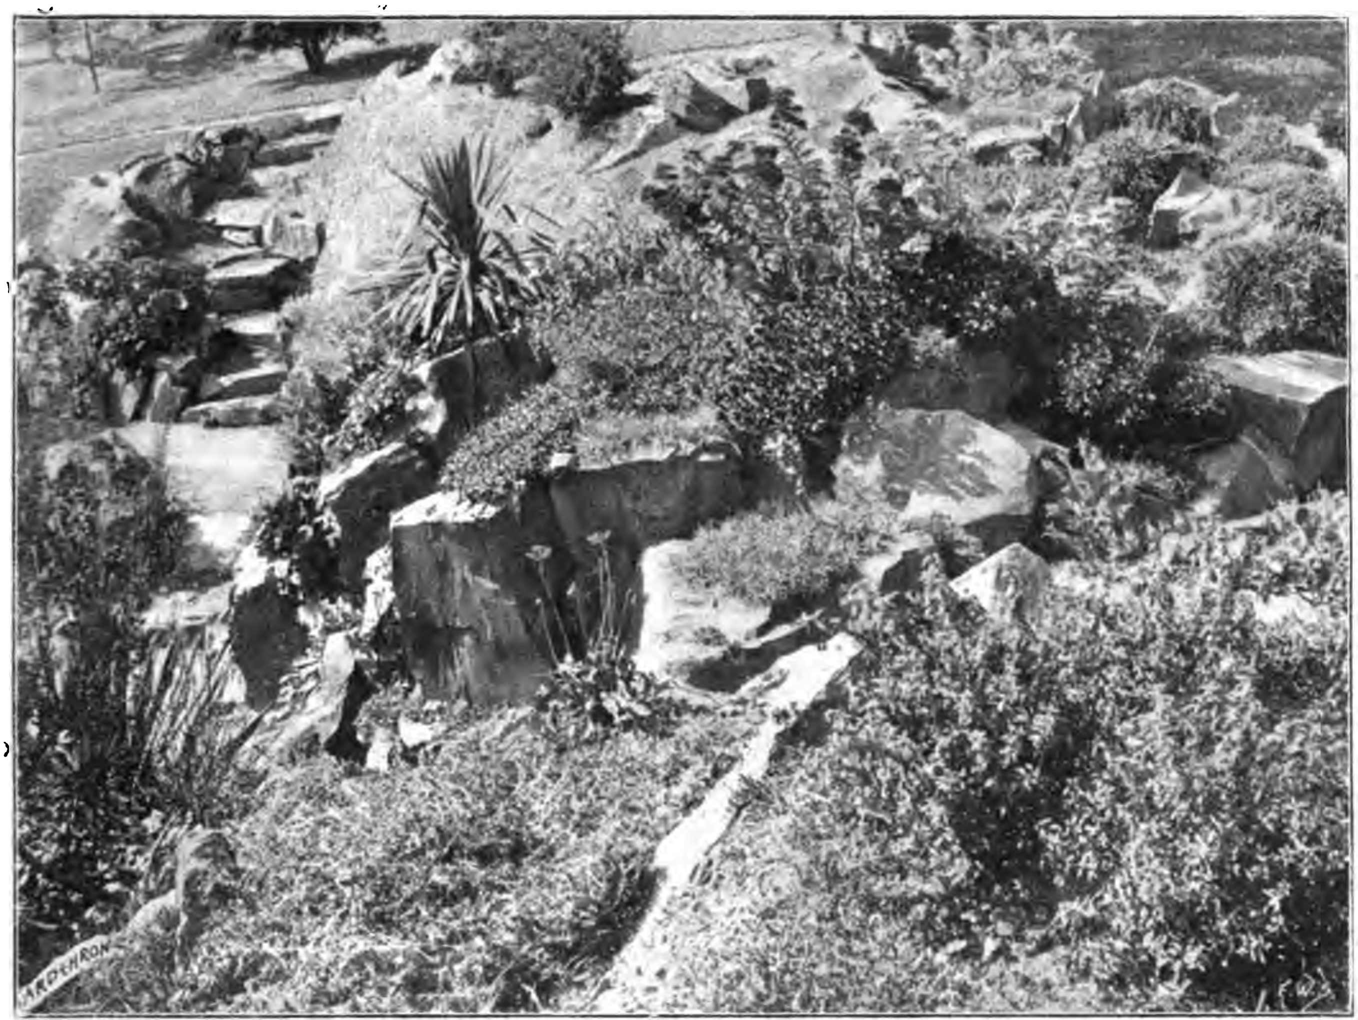

Fig. 115.—Part of Rock-garden, Little Silver, High Bickington, South Devon. (See p. 311.)

Herbaceous plants are found in beds and borders in suitable places in the gardens, such as Alstrœmerias, Delphiniums (including various and beautiful shades of blue), Doronicum Harpur Crewe, Echinops Ritro, with its prickly heads of blue flowers, Eryngium amethystinum, the silvery Thistle-like foliage, surmounted by heads of metallic-blue flowers, being very handsome and telling in effect, Gaillardias of the grandiflora type, &c.

The conditions in the kitchen garden go to show that grand crops of fruit, vegetables, and flowers can be obtained even during a dry season like that of last year, if the soil be kept moist.

Fruit-trees of the best kinds and varieties have been planted against walls, and on either side of the walks within the last eight or nine years, and the growth of these trees has been guided by skilful hands; and the trees were of such Plums as Kirke's, Denniston's Superb, Coe's Golden Drop, Green Gage, Reine Claude de Bavay, Transparent Gage, and Victoria. The Peaches and Nectarines succeed well on south walls, and the trees were clean in foliage and well trained. A Black Hamburgh Vine on the same wall is in fine condition, and bears in its season a fine crop of fair-sized bunches, which usually ripen well. Espaliers or horizontally-trained Apples (young trees) of Irish Peach, Beauty of Bath, Ribston Pippin, and Cox's Orange bear good crops of large, clean-skinned fruit, and Ribston Pippin comes especially fine and good. A fine old tree of Louise Bonne of Jersey covers a wall-space of 288 square feet, and on the lower branches of this tree there have been engrafted scions of Glou Morceau, Beurré Diel, and Bellissime d'Hiver, with the result that the tree is furnished with healthy, short-jointed wood, and in most years plenty of fruit. I may here remark that this and many other wall trees Mr. Kerry, the gardener at this place, found with shoots crowded together, and standing from 12 to 15 inches out from the wall when he took charge of the gardens some nine years ago. By a persistent and judicious pruning year after year, he has succeeded in converting the neglected, almost barren trees into shapely, fruitful ones. The old spurs having been severely thinned out the first year, and those retained trimmed into shape, young shoots perforce pushed from the main horizontal branches, these being duly pinched and pruned, formed spurs and fruit-buds close to the branches, and the remaining projecting spurs or branches were removed altogether to make space for young ones. A fine tree of the Brown Turkey Fig occupies a south-eastern aspect between two buttresses of the wall of the church, the shoots being allowed proper space on the wall to develop, and at the same time benefit by exposure to the sun's rays. A plantation of Superlative Raspberries is well worth seeing, the canes being from 6 to 8 ft. high and very thick. They bear heavy crops of extra large fruit, fine in colour and flavour.

The glasshouses consist of two vineries, a stove, an orchard-house, a conservatory, a cool-house, Melon and Cucumber pits and frames. The crops of Madresfield Court, Black Hamburgh, and Muscat of Alexandria Grapes were very satisfactory. In the stove, well-grown plants of Dendrobium nobile were observed; and in the conservatory and cool greenhouse were noticeable several fine specimens of Campanula pyramidalis alba, as well as the blue variety, having spikes of well-developed flowers, about 7 feet high; Habrothamnus elegans, trained up a back wall, was profusely flowered; tuberous-rooted Begonias and Celosia pyramidalis coccinea and C. p. aurea showed good culture, and made a nice display.

In conclusion, I may be allowed to say that Mr. S. Kerry (who was a pupil of the late W. W. Wildsmith, and the last man whom he assisted into a head place) is an enthusiastic gardener, and he is to be congratulated upon having employers who take such great interest in their garden and in gardening generally as Mr. and Mrs. Parker, to whose kindness on the occasion of my visit I feel indebted. *H. W. W.*

VARIATION.

MANY years ago I had the pleasure of visiting a high-class turning establishment in London, and seeing some of those wonderful compound lathes by which the more complicated and varied designs are worked out in hardwoods and ivory. In these lathes, besides the ordinary revolving motion imparted to the article, the chucks holding it were also capable of lateral perpendicular motion, ranging from horizontal straight lines to perpendicular ones through all grades of the oval, and even through figures of eight. The cutting tools were also actuated to perform independent motions of their own, so that when brought into contact with the faces or sides of the object operated on, their eccentric cuts formed combinations with the eccentric motion of the object, the result being patterns of marvellous complexity and perfection. To attain these results, discs of metal were attached to the apparatus, with holes in their margin numbered from 1 to say 360, and the combinations were determined exactly by means of pegs inserted into these holes in such numerical orders as formed divisions without a remainder. A cut, therefore, forming a figure of 8, or a narrow oval, could be made in a flat surface either 360 times, each one at a distance of 1-360th from its neighbour, constituting an extremely fine pattern; or it might be cut only 180, 90, 45, 120, 60, 30, 15, or, indeed, as I have said, any number into which 360 can be divided without a remainder, so that at a complete turn of the disc the same starting hole is reached. Clearly every alteration of number alters the pattern, as does every change in the width of the oval or figure of 8, and further, so does every alteration in the depth of the cut; while if the cut face be moved, at same time another set of changes is worked in, and in fact an infinite variety is obtainable. Furthermore, it is obvious that symmetry of pattern depends upon the numbers being correctly calculated, since if these do not count out properly there is either a gap or an overlap when the final cut is made. Finally, I was shown a series of books filled with nothing but numbers, each set of which represented an intricate pattern which was bound to appear when the pegs were adjusted to the controlling discs in accordance with the figures.

Now, it has frequently occurred to me in studying the phenomena of variation in plants, and especially in Ferns, that we have something akin to this lathe business underlying the "sports," i.e., the abnormal forms, symmetrical and unsymmetrical, constant and inconstant, of which such an extraordinary number exist. We have not, of course, to do with actual numbers, but we have to do with complex workings within the cell, which normally work out on certain definite lines known as specific or generic ones. Some forces pull one way, some another, and in hybrids and crosses this conflict is accentuated. Two sets of numerical discs, to adopt the parallel for the sake of the argument, are introduced into the machine, and if these numbers harmonise, that is, count out without remainders, we get a symmetrical and constant cross or hybrid; but if these do not, reversion or imperfection of some sort is constantly occurring, the equilibrium is unstable, and no amount of selection from the offspring of such imperfect plants can make odd numbers even ones. On the other hand, if the combination be a specially happy one, a perfect fit, so to speak, it may be expected to persist, and breed true to type. The molecular theory teaches us that the atoms of everything, organic or inorganic, are in a perpetual state of vibration, and we may reasonably assume that every living plant has its particular harmony established between the varied elemental atoms composing it. Hybrids and crosses involve, therefore, complex combinations in which harmony comes out as constancy, and discord as inconstancy, precisely as exact and inexact adjustments of the lathe aforesaid mean regular or irregular work, that is, successes or failures. We know, indeed, so little of the marvellous inner workings of nature that at present we are but groping in the dark with our experiments and studies, but it is quite conceivable that a fuller knowledge would enable a mathematician to calculate to a nicety what the result of a cross would be by calculation of the potencies of each parent. This, however, we predict will require a long string of Victorian eras of progress to bring about, and meanwhile we can only work hard, experiment freely, and glean as much as we can from the results obtained. *Chas. T. Druery, F.L.S., V.M.H.*

THE FRUIT-TREE BARK-BEETLE.

(SCOLYTUS RUGULOSUS, RATZ.)

ON May 16, 1898, Prof. E. A. Popenoe wrote from Topeka, Kans., that in a search for trees attacked by this species in different portions of Kansas, many rows of trees were examined, and in nearly every tree affected the top was blighted, or a stump remained whence a blighted branch had been cut. Beetles were also noticed in Pear-trees whose leaves were coloured so as to indicate ill-health, and were found to be also diseased at the root below the budding point. Many of the diseased trees showed the beetles just beginning work, precluding the possibility of the appearance of disease resulting from the beetle attack. The conclusion was reached that the diseased trees were preferred by the Scolytus as a place of oviposition. In a few trees, however, the beetles were found at work where there was no sign whatever of ill-health in the tree attacked, thus corroborating statements of like nature previously made by the writer.

Mr. Ernest Walker, of Clemson College, S. C., wrote on May 18 that this species was doing damage on Prunus Simoni, and Japanese Plums.

Mr. J. C. Andrus, Manchester, Scott County, Ill., stated in a letter dated May 15 that in his experience this species attacks Mountain Ash and Juneberry (Amelanchier canadensis), both new food-plants for this country, and the latter unrecorded.

In response to inquiry in regard to remedies, Mr. C. C. Beals, of New London, Howard County, Ind., wrote under date of August 23, that this insect made its appearance at that place about the middle of July, peppering the bark of the Cherry-trees with holes, and running about over the bark. In two or three days after the first-noticed appearance, a tree was sprayed with kerosene, but this had no apparent effect. The kerosene was then rubbed upon the trunk and larger branches, with the result that all the beetles were killed. At the time of writing, the tree was doing well. Writing again on October 25, Mr. Beals stated that although the kerosene killed the insects with which it came in contact, the experiment was not an entire success, for the reason that the smaller branches and twigs were not treated.

As still further corroboration of the statements previously made, that this species will attack healthy trees, the writer observed during the season of 1898 in the same orchard mentioned in the footnote on p. 3 of the circular, a perfectly healthy Apple-tree, which had been attacked evidently several years previously, judging from the nearly obsolete scars on the trunk. Specimens of the beetle, dead in two or three of the burrows, showed beyond doubt that this was the species concerned, were it possible to mistake its work for that of any other known Scolytid. The Apple-tree had entirely recovered from attack.

The Peach-tree mentioned in the same footnote as apparently perfectly sound except for the attack of the beetles, was again attacked last fall, and will be kept under observation, as it is probable that it will not be able to survive more than one or two years under the circumstances. The particular place selected by the beetles for their principal attack in 1897 showed the presence of "sun scald" early in the succeeding summer. Later this space, which was on the main part of the trunk, was found to be badly infested with the Peach-borer (Sannina exitiosa). Some of the smaller branches had attracted another well-known borer of the Peach, Phlœotribus liminaris, Harr., and the tree now shows the effect of attack, although no beetles have yet bred from any except one dead branch.

The presence of this bark-beetle in trees infested by the San José scale, as mentioned on page 2 of the circular, was again noticed in the present year, but Messrs. W. G. Johnson and F. M. Webster have both informed me that this is unusual.

Chiropachys colon, Linn., the most abundant and destructive parasitic enemy of this bark-beetle, was noticed abroad the past year as early as April 9. *Extracted from Bulletin No.* 19, *New Series, U. S. Department of Agriculture, Division of Entomology.*

FLORISTS' FLOWERS.

AURICULAS AT BRACKNELL, BERKS.

THE centres of Auricula-culture change, and somewhat rapidly. Slough at one time used to furnish Auriculas that could hold their own against all comers, but that is so no longer, though occasionally a few superb alpines come from there. Then Loxford Hall, and Great Gearies, with Mr. James Douglas, became important centres, Rev. F. D. Horner coming occasionally from the North to try conclusions with him. Then Reading, with its band of enthusiastic amateur cultivators, became an active centre, and yet at the last exhibition of the National Auricula Society not a plant from Reading so far as I know of was shown. Mr. Douglas, who in his time has raised several good varieties, still grows at, and exhibits them successfully from Bookham, but not with the striking success of a bygone time. Mr. C. Phillips, at Bracknell, and Mr. W. Smith, at Bishop's Stortford, appear to be rapidly coming into the front rank in the near future, but a probable important point of Auricula cultivation will be Bracknell.

Mr. Phillips, though retaining his position as the manager of a local bank, has embarked in business at Bracknell, and taken as a partner Mr. James R. Taylor, who was for seven years gardener to H. R. H. The Duke of Connaught, at Bagshot Park. So far, the nursery, if such a term may be applied to such a restricted space, consists of three glass-houses, one devoted in spring to Auriculas, and the other two to Carnations. These will be the leading specialties, Mr. Phillips having succeeded in getting together a remarkably good collection of Auriculas, and he is particularly successful in their cultivation. The open, breezy country side of Bracknell appears to afford the plants just the conditions of healthy development they require.

At the time of my visit the collection was in good bloom. A broad span-roofed house, with a stage on either side, was full of show and alpine varieties, one stage being filled with the former and the other with the latter forms. Of green edges, Mrs. Henwood was seen to the best advantage; it is a flower of fine proportions, raised by the late Samuel Barlow, producing a stout stem and a bold truss of excellent pips, and it is also a vigorous grower. Like Simonite's Rev. F. D. Horner, it is a certain exhibition variety, and these two being so constant, are likely to stand at the head of the green-edged section for some years to come. Abbé Lizst is a very bright variety, of good habit, but rather open in the tube; it is still scarce, and being so, is perhaps somewhat severely divided in order to procure stock; there is great promise of usefulness before it. Horner's Monarch, shown as a seedling in very fine character, appears to be quite unreliable, coming confused, and even semi-double; it has a good tube, paste, and body colour; time may correct these floral vagaries. The fine old Prince of Greens, up to a few years ago our leading green edge, increases but very slowly in the south, and will therefore be always scarce and dear; it seems to do best in its northern home. Lovely Ann was to be seen here with its bright green edge; also Simonite's new green edge, James Hannaford, with a very few older varieties.

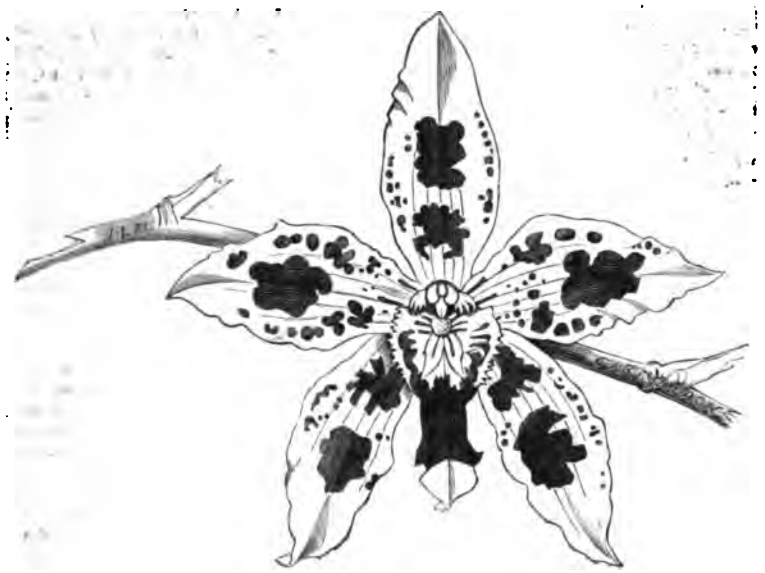

FIG. 116.—ODONTOGLOSSUM CORADINEI: WEST BANK HOUSE VARIETY.
Ground colour lemon-yellow, with brown blotches and red-brown dots.

Of grey edges, George Lightbody, raised and named by his old friend Richard Headley, and Richard Headley raised and named by George Lightbody — a touching memento of the warm friendship which existed between these two men until death severed it—stand at the top of the section. Both are superb varieties, but R. Headley is late. When at its best, as I saw it at Bracknell, it is rich, striking, superb; the leaves of this variety are freely mealed on the edges. Headley's Alderman Wisbey, though classed with the green edges, was here, as is sometimes the case, a capital grey edge. Dinham, raised by the late Mr. R. Kyrke-Penson, is a capital flower when caught in good character; it lacks refinement, which will doubtless come with culture. Old Robin Lancashire's Hero, which is now known as Lancashire Hero, was also in good form, and considering it has been in cultivation more than half a century, holds its own among the peers of the grey edged section. Dr. Kidd (Douglas) was in good character; and also William Brockbank, with its glorious golden tube and dense white paste, but with the unfortunate tendency on the part of the pip to recurve on the edges. George Rudd, Marmion, Rachel (at times an excellent white edge), and Mabel, all good varieties, are also in the collection. George Rudd is a most useful "grey edge," as it is a variety always to be depended upon, and it will perpetuate the memory of its raiser, Woodhead, for many years to come. At times it is almost a "white edge;" it has a rare body colour, and good petal. Rachel, by the same raiser, is very like it, but is not so strong in the tube or so compact in the truss, and is liable to rot at the tap-root. Marmion is mostly a "white edge," and is, perhaps, one of the best Auriculas Mr. Douglas has raised, but the pips do not expand kindly.

Acme is the most useful "white edge," because so constant, having also such a rich tube, and handsomely-mealed foliage. It is the only flower raised by Mr. John Read which remains in cultivation; as it throws offsets very freely, it is both plentiful and cheap. Conservative (Douglas) comes near to it, but the foliage has little or no meal. Other good white edges are Walker's John Simonite, Woodhead's Mrs. Dodwell, Simonite's Heather Bell, and Mellor's Reliance.

Mr. Phillips confines himself to but few selfs; one of the most useful is Woodhead's Black Bess. Horner's Heroine is not so good at Bracknell, and it is apt to come shaded on the edge; yet cultivators and exhibitors will always be grateful to Mr. Horner for this variety, for it gave them a model of form in self Auriculas—when at its best, it stands at the top of its class. Barlow's Mrs. Potts is a self flower of almost perfect finish as a blue self, but it has a weak tube in common with the blue selfs, and a weak flower-stalk, while its growth of leaves is tall and ungainly. Ruby (Simonite), is a bright red self, a great improvement upon Lord of Lorne, having a finer pip, stronger tube, handsome mealed foliage, and is a great acquisition. Mr. Phillips has himself raised two fine dark selfs, one, Miss Barnett, is already in commerce; it is of a rich claret colour, tube, paste, and shape, all remarkably good; and Mrs. Phillips, maroon-crimson, a companion flower in point of general good qualities. The fine yellow self Buttercup (Horner) is also in the collection; and one very similar, raised by Mr. Phillips.

It is as a raiser of alpine varieties in particular that Mr. Phillips has made his mark, and he has probably raised and named as many as fifty, with finely-shaped smooth pips. Of golden centres his best varieties are May, Evelyn Phillips, Mrs. Martin Smith, Chastity, Mrs. Gorton, Saturn (very bright), A. R. Brown, Little Gem, Topsy (a brilliant variety), Dreadnought, Dr. Jameson, Regina, Cassandra (extra fine), Miranda, Mira (a superb variety), and Princess Louise. White centres: Perfection, with its exquisitely-shaped pip; New Colour, very distinct; Gladys, and Sister Mary. There is ample room for improvement in the white centres, and Mr. Phillips is in a fair way to secure it.

There is also a general collection of Carnations filling a large house, now that they are potted up for blooming, including Malmaisons in some sixteen varieties, which are to be made a leading feature, and winter-flowering sorts. A fine yellow-ground Picotee, raised and named by Mr. Phillips as Lady Clementine Walsh, is very early to bloom, and a robust grower. In addition, there are a considerable number of seedling Carnations in the open ground.

Violets are to be a specialty, and already a large number are planted out. The leading double varieties are Marie Louise, Lady Hume Campbell, and de Parme; single varieties: Princess of Wales, Princess Beatrice, The Czar, W. W. Astor, California, &c.

A well-chosen collection of herbaceous plants is already formed, and new ground is being broken up by way of extension. A goodly number of seedling Carnations of the best blood, from spring-sown seeds, is also coming on for succession. *R. D.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM × CORADINEI, WEST BANK HOUSE VAR.

As with most Odontoglossums, so in the representatives of this natural hybrid between O. Lindleyanum and O. crispum, there is much variation. The ordinary forms with their narrow pale yellow segments, bearing a few brown blotches, being esteemed only superior to O. Lindleyanum; while the remarkable varieties, which are however very scarce, are fit to rank with O. triumphans and others of the showier section. In both good and bad forms, the long straight column followed for the greater portion of its length, by the basal part of the labellum, is a characteristic showing the affinity to O. Lindleyanum. The features of the indifferent varieties are distinctly those of O. Lindleyanum modified by O. crispum, while the good forms in their broader ovate-lanceolate outline, show O. crispum changed and coloured by the influence of O. Lindleyanum. Therefore we may conclude that the cross has been effected both ways.

A flower of the handsomest variety I have yet seen, and which, in its good form and bright colours, imitates O. triumphans, has been received from J. Leemann, Esq., West Bank House, Heaton Mersey (gr., Mr. A. Edge), with whom it has flowered among imported Odontoglossums (fig. 116). The sepal and petals are ovate-lanceolate, and nearly equal in width. The ground colour is lemon-yellow, changing to nearly white towards the base. The sepals each bear in the middle one large chestnut-red blotch, about ½ inch in length, and one smaller blotch towards the base, the margin having a chain of small red-brown dots. The petals have the large chestnut-red blotch on the outer half, the lower parts and margin bearing clusters of small red-brown spots. The tip of each segment is bright yellow. The lip, which is showier than the ordinary varieties, though of the usual form, has the blade, except the apex, chestnut-red, the base cream-white with red lines.

COLONIAL NOTES.

TASMANIA.

A CORRESPONDENT in Launceston, Tasmania, writes as follows:—"I may say that our harvest has been very plenteous, but, sad to say, prices are low, the prices offering for Wheat being under 2*s.* per bushel. There is a movement to try and open up a trade with England, but I doubt of its success. Our Apple crop has just come in, the *Britannia* sailing last week with the first shipment for England. Unfortunately, we have so many pests to contend with, that any one blessed with a garden or orchard has to be continually at work spraying the foliage or bandaging the stems of his trees, in order to mitigate the nuisances to some extent. We have just experienced a month of very hot weather (rather exceptionally so, as the early part of the summer was very cool); this was very acceptable, as the vegetable-fruits, Tomatos, &c., were very backward, but the hot weather has brought them along nicely." The above communication was despatched last February. *O. M.*

TETRATHECA PILOSA VAR. FLORIBUNDA.

This is a much branched, compact, and heath-like, glabrous, or hispid shrub, seldom exceeding 1 or 1½ foot in height, flowers axillary red, pink, and sometimes white. It is a native of the Mount Lofty ranges, S. Australia. Amongst our numerous species and varieties of Tetratheca, the above described variety is by far the showiest. It is very easy of culture. Seeds germinate very readily, and it can easily be propagated from cuttings. *O. E. Menzel, Aldgate, S. Australia.* [With this came splendid specimens covered with flowers, which retain their brilliant colour when dried. The photograph sent, shows a well-grown plant full of bloom in a large pot, but the outlines of the flowers are too indistinct to enable us to reproduce it. It would make a magnificent specimen plant at an exhibition. Ed.]

DOWN HOUSE, BLANDFORD.

The seat of Sir W. H. S. Marriott, Bart., is about two miles from the town, and is at all seasons a place of considerable interest. The park and grounds are extensive, and the size and general appearance of the trees prove that the larger number of them flourish, though the surface-soil on many parts of the estate is scarcely more than 8 inches deep. Beech, Lime, Elm, and Ash appear good, and of Conifers there are many grand specimens.

The glass-houses are numerous, and well furnished with plants. Sir W. Marriott is well known to be a keen collector and good judge of Orchids. Many of these plants were disposed of some years ago, and it was interesting to listen to the noble proprietor and his gardener, Mr. W. Denny, as they described to me specimens that had grown and flowered here in days gone by.

The first house we entered was devoted to the Odontoglossums. More light appeared to be given the plants than is customary, and the purple colouring of the bulbs and leaves would seem to indicate that robustness followed this kind of treatment, for the flowers were remarkable for their size and vigour. In a case at the back of a portion of this house, kept constantly moist, were large plants of Todeas superba and pellucida, Trichomanes radicans, and other filmy Ferns. Dendrobium Jamesianum was represented by numerous fine plants. Odontoglossum coronarium is cultivated in baskets, but, as in many other places, it does not flower very freely.

In another house Cypripediums are cultivated with much success, and in every house devoted to Orchids it may be seen that the raising of seedlings is carried out persistently, and with intelligence.

Dendrobium Phalænopsis is grown in quantity, the bulbs of recent growth being even finer than many of the imported ones. Lælia cinnabarina and Cattleya Skinneri grow close to Adiantum Farleyense, whilst over all is a large plant of Allamanda Hendersoni. The Cattleyas are cultivated very successfully, and include specimens of great interest. In addition to the fine collection of Orchids, there are vineries, Peach-houses, Melon and Cucumber-houses, all of which are managed with conspicuous ability. The kitchen-garden is cropped fully during the season.

THE PLEASURE GROUNDS.

There are trees of Cupressus Lawsoniana 40 feet high, and Sequoia gigantea 60 feet. Abies Smithiana is a fine specimen; Cedrus Deodara, Taxodium sempervirens are well relieved with clumps of Retinospora plumosa aurea. An Abies Pinsapo is just 50 feet high. A. Nordmanniana is represented by many perfect specimens. The Yew Maze is in capital condition; Walnuts and noble Beech trees and Oaks constantly come into view, with Cupressus macrocarpa, Abies Douglasii, immense Scotch Firs, and avenues of Limes. In other parts were avenues of Hornbeam. *Traveller.*

THE WEEK'S WORK.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

The Spring Garden.—Most of the spring-flowering plants will now have passed their best for the season, and should be taken up and propagated by various methods. The varieties of Polyanthus, known as Dean's strain, are charming spring bedders, hardy, and very effective. The plants, when lifted, should be divided into pieces with three crowns each, and the flower-stems and seed-vessels pricked off, and then be planted in rows on a partially shady or north border. The Polyanthus succeeds in a retentive soil, enriched with cow-manure. Seed of these plants may now be sown in boxes, and placed in a cold frame. When large enough prick them out 6 inches apart in beds, and they will make serviceable plants this year. All hardy species of Primulas succeed when treated in this manner.

Daisies, which are also fine plants for spring-bedding, are of easy culture, and form fine masses of colour when thickly planted. The ordinary double flowered crimson and white varieties are the best for bedding purposes. Only large clumps of Daisies should be divided, as flowering greatly exhausts the plants. These pieces should be planted in a light, open, cool position, using good sandy loam about the roots in planting them, and affording shading from sunshine, and a sprinkling overhead after sunset until established. Afford plenty of water to the plants in dry weather. The variety Aucubæfolia, which has spotted leaves, is not so effective as a bedder as those Daisies which have green leaves. Daisies may be raised from seed, which should be sown during the present month.

Myosotis dissitiflora is an early-flowering Forget-Me-Not that does well in the beds here, providing young seedling plants are used. M. sylvatica is also very effective, and the plant is more compact than the first named. Both are raised from seed, and sown this month in the open border. M. alpestris Victoria is a compact grower, but it is quite a fortnight later in flowering than these. It is propagated by division. All Myosotis succeed in cool, moist ground, that is not made too rich.

Arabis albida, with variegated leaves, make a pretty effect planted alternately with Myosotis. A. lucida folia variegata is very effective as an edging plant of miscellaneous beds, remaining bright throughout the winter. Stachys lanata makes an excellent bordering to Tulip-beds; Alyssum saxatile compactum is late in flowering, but it makes an excellent edging to permanent beds, the variegated variety keeping its colour best when planted in poor soil. Violas are late in flowering this year, and generally have to be removed in full beauty, to make way for the other bedders. Aubrietias, too, are late this year. They succeed best in a position where they are not disturbed yearly.

Beds.—As soon as the plants are lifted, dig the soil deeply, leaving it in a rough state. After this is done add some loamy soil which has been exposed to the weather and is pulverised, and sufficient leaf-mould, according to the requirements of the plants which will be set out. Some beds need only to be raked over to make them fit for the reception of the summer flowering plants.

Flowering Shrubs.—Forsythia suspensa should now have the shoots that have flowered shortened, leaving three to four buds, and allowing the terminal shoots to grow and hang down. Growths quite near the ground, and shaded by the upper ones, are better cut away. Ribes, both single and double-flowered varieties, should now be pruned, cutting back the shoots that have flowered, and afford a dressing of manure, or liberally apply manure-water if any of the shrubs are weak. Mahonia aquifolia, if cut back hard after flowering, will push growths and become more decorative than when it is allowed to grow unpruned and show the leafless stems.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore Maidenhead.

Mulching.—Remembering the drought of the past two or three years, the gardener will be exercising caution if he carry out a system of mulching for the Pear and Peach-trees growing on south and west walls, and the bush-trees everywhere, as Apples, Plums, and Apricots. This is the more necessary in light soils, or where the subsoil is gravel, sand, or rock. As a mulch for fruit-trees and bushes, nothing is better than half-rotten manure from the stables; and if the surface-soil is very hard, it should first be hoed over, or very slightly pointed over with a digging-fork or "graft." Young trees making strong growth will need no mulch; or if it be afforded, half-rotten bracken, or spent hotbed-manure, will suffice. The suckers, which nearly always arise from the roots, of the Plum-stocks on which Peaches and Plums are worked, must be carefully removed, by scraping away the soil, and cutting them off close to the root.

American Blight (*Schizoneura lanigera*).—This woolly aphis chiefly confines its attacks to the Apple in old orchards, and, as with most other insect pests, dry, warm weather conduces to rapid increase, means should be taken forthwith to exterminate the aphides; they are mostly to be found on the stems and older branches, where the crevices in the bark abound. An efficacious means of ridding a tree is to scrub all infested parts with soft-soap or Gishurst Compound, using about 3 oz. of either to 1 gallon of hot water, working it up to a lather, and applying it with a moderately stiff scrubbing-brush. Syringing the trees with any of the usual insecticides may also be practised, the Quassia extract, in which soap is also dissolved, being a good one for this purpose. The soapy lather should be used on the old wood only. In the winter season various remedies may be safely applied, but at the present season less strong insecticides can only be employed. Heavy syringing by means of the garden-engine and Quassia-water does no harm to the young growth, and it certainly clears a tree of great numbers, and a dressing of freshly-slaked lime applied to the ground, and a good trampling afterwards, will finish off those washed off the tree. In bad attacks the aphis may be found on the roots near the surface, and these should be laid bare, and the soil drenched with soapsuds, returning the soil directly afterwards. By this means great numbers are killed; but the dressing ought to be repeated thrice a year at the least.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Caladiums.—If specimens of a large size are wished for, the plants should be shifted into larger flower-pots as soon as the roots have permeated the soil of the previous potting in every direction, affording them a compost consisting of equal proportions of fibry turf, peat, and flaky leaf-soil, together with a small quantity of dry cow-manure which has been passed through a half-inch meshed sieve, and abundance of coarse sharp sand, the turf and peat being made use of in as lumpy a condition as the extent of the shift will admit. A moist atmosphere should be maintained about the plants, but these should not be syringed overhead, as the deposit from almost all kinds of water spoils the appearance of the foliage. Shading should be afforded only during very bright sunshine. [Some gardeners never shade these plants. Ed.]

Nerines.—These autumn-flowering bulbs are now entering the resting period, and will need only an occasional application of water till the foliage dies down, when no more should be afforded. In the dry state the bulbs may be placed in a cold frame, or upon a greenhouse shelf, exposed to the full sunshine until the autumn. If the plants are placed in a frame the light may be removed during fine weather. The plants should be kept quite dry until signs of starting into growth are apparent in the autumn, at which time any repotting that may be necessary should be carried out.

Miscellaneous.—Let the points of Euphorbia jacquiniæflora cuttings, when they have taken root and began to grow, be pinched out once only, and shift them into somewhat larger pots after they have broken afresh. Also take the points out of Hibiscus Manihot when the seedlings are 3 or 4 inches high. Stop the shoots of Bouvardias, Manettia, Libonias, Ixoras, Tecoma Smithi, &c., occasionally, to induce a bushy habit. Remove all flower-buds, except the terminal one, on Souvenir de la Malmaison Carnations, if blooms of extra large size are required.

THE KITCHEN GARDEN.

By H. Markham, Gardener at Wrotham Park, Barnet.

Tomatos.—Let these plants be kept progressing, and make the growth sturdy by affording them ventilation in good amount, and do not deprive them of root-space. At one time gardeners believed that this plant fruited best when it was pot-bound and starved; but my experience has shown me that the best results are obtained from plants that are well treated from the first. The ground at the foot of the walls against which Tomato plants will be planted should be dug deeply, after dressing it with a fair quantity of short, decayed stable-dung, lime-rubble, and fresh soil, these additions being well mixed with the staple, and the whole made very firm. Strong, well-hardened-off plants may now be put out in the warmer parts of the country, some protection being afforded if frost threatens. In less forward parts the end of the month will be early enough to plant.

Celery.—Those plants which were pricked off some time ago will now be fit for planting at 6 in. apart, on a well-prepared border, the plants being carefully handled. The nursery-bed should be rendered fit for the reception of the plants by mixing decayed manure or leaf-mould with the upper layer of soil, and making a fine tilth, a small quantity of soot being finally sprinkled over the surface. Afford the beds good applications of water in bright weather, and slightly shade them for a few hours daily during the first week. The seedlings of Leicester Red, a good late variety, being now large enough, should be pricked out before they become spindly and weak. Before taking them out of the seed-bed, soak the latter with clear water, and also the nursery-bed. If aphides infest the plants, apply Quassia-water or soap-suds with a syringe.

Vegetables.—It is good practice to cut or remove all sorts of vegetables required for the day before the sun gets powerful, as then the quality is finer, especially so in the case of Cauliflowers, Lettuce, and Coleworts. If they are to be sent to a distance by rail or other conveyance, it is very essential that vegetables should not be allowed to wither from exposure to wind or sun, but that they should be placed in a cool, moist place till they are packed in the hampers. The coarser vegetables should be collected first, and the finer ones at the last moment. These may be laid out separately, and sprinkled slightly with clean water if the weather is very hot. Vegetables to be sent by an early train must be gathered the previous evening, and covered with a damp mat, the packing taking place in the morning. Asparagus, French Beans, herbs, &c., should all be neatly tied up with bast in bundles, and should be placed at the tops of the hamper, with the edible tips of the first-named made secure against bruising.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

Melons.—Periodical sowings in number according to the demand and space for planting should be made fortnightly. The pit or house now occupied by the early crop can be utilised for a late summer one, sowing, and forwarding plants in pots, so as to have them strong by the time all the early fruits are cut. New soil should be substituted for the old before planting out a new stock of plants. The soil cannot in reason be made too firm. Some soils favour canker in the stem more than others, not only giving a deal of trouble, but requiring special treatment from the early stages onward. Portland cement is an excellent antidote when canker is present in the stem, rubbing it well into the affected parts after they have been scraped with the back of a pocket-knife. Plants in flower, and others approaching that stage, will need immediate attention in respect to the pollination of the female blooms. Regulate the growth by pinching, so as to obtain the required number of female blooms to open at the same time. If large fruits are desired, liberal feeding with liquid and artificial manures must be given, but the utmost care should be exercised in regard to the quantity applied. Green and black-fly can be kept under by syringing with insecticides, quassia extract being particularly effectual and safe in use; or by fumigating.

Melons: later crops.—The fruits, if they have attained the size of a cricket-ball, will need support, and nets made expressly for the purpose are the best, although a three-cornered or a square piece of board suspended by small pieces of string are in common use. To prevent the decay of the fruit, a hole as big as a penny should be cut in the middle of each piece, or the board may be hung so as to slightly incline to one side, so as to get rid of the moisture falling on it.

Early Figs in Pots.—These trees will have been affording ripe fruits, but the production will soon cease, unless there are numerous trees. After a crop is finished, the entire surface soil which can be readily removed should be taken away, and a top-dressing applied of fresh loam, lime-rubble, and a sprinkling of some artificial fruit-manure, for the encouragement of root-activity, and assisting the development of a second crop of fruits, which are now in an advanced stage. Diluted liquid-manure may be applied twice or thrice each week, if the pots are well filled with roots. The stopping of growths must be frequently attended to so as to get the wood matured, and embryo Figs to form. In regard to moisture, do not be misled by the damp appearance of the top-dressing, whilst the soil below it may be comparatively dry.

Figs Planted Out.—The fruits on such as were started early will be approaching ripeness in some instances, and syringing should be less frequent, and a dryer atmosphere obtained by increasing the ventilation of the house, and doing less damping down. A thorough application of water should be afforded the borders, if the trees are long-established ones, and the border is restricted in area. This matter ought to receive attention before or about the time of the final swelling of the fruit. In the case of old trees, liquid-manure is of much benefit to the present and to succeeding crops. Figs are exempt from insect-pests, though sometimes scale and red-spider infest the stems and leaves. Sponging with soapy-water forms the best remedy. Figs improve by being kept for a day or two after gathering before being sent to table. Trees in cool houses should once a week have the shoots stopped and regulated according to the amount of wall-space, as crowding of shoots should be carefully avoided. Large trees are the better for being stopped at short intervals of time, as then a succession of fruit is easily obtained. It is better to stop often than to rob the trees of a great lot of foliage at one or two operations, a method that leads to fruit dropping. Those that have filled the trellis, and are fruited on the spur principle, will require the minor laterals to be pinched back, as they are made, to within one joint of the base, the aim being the exposure to sunlight of every leaf made, so that growth may become fruitful.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Cypripediums concolor, Godefroyæ, and niveum.—Any plants of this difficult section of the Slipper family that require to be re-potted or top-dressed should be given attention at once, so that they may have the whole of the season in which to make what progress they will. These species may be grown in pots or pans, but the latter should not have any side perforations; and instead of using potsherds for drainage, substitute pieces of limestone, old lime-mortar, or tufa. When re-potting, hold the plant in position, and work in the limestone, mortar, or tufa amongst the roots to within an inch of the rim, filling the remaining space with a compost of one-third fibry loam, one of peat, and one of sphagnum-moss. The base of the plant should be raised well above the level of the pot. Subsequently the plants may be placed in a position near the roof glass in the hottest house, where no water from any source is likely to get into the growths. The water necessary for the plants should be supplied by dipping the pots to their rims, to prevent a chance of water lodging in the axils of the leaves. A moderate amount of shade is required by the plants during bright weather. The chief danger lies in giving water too often during the winter, and in the lodgment of water in the axils of the leaves.

C. Godefroyæ leucochilum is more easy of cultivation in hot-house than others of the section. It should be grown in pans of moderate depth, suspended from the roof of a warm-house, and where drip does not accumulate. An ordinary Orchid compost, with crocks for drainage, is all that the plant requires. Afford water sparingly, and rather more shade than is advised for the above-named species.

C. bellatulum.—After repeated trials to grow C. bellatulum in a high temperature, we now place our plants in an intermediate-house, in which Miltonia vexillaria is grown, and judging by two years' experience the result is satisfactory. When once established, this species should not be disturbed until absolutely necessary. Newly-imported plants should be thoroughly washed, and then hung head downwards for a week or so. Afterwards place them in pans as advised for C. concolor, suspending them in a moderately shady house with a temperature ranging between 58° to 63°. Established plants may occasionally be re-surfaced, but as they do not require much water, the soil keeps in a good state for a long period of time. C. bellatulum album is grown here suspended under the central ridge of a small Cattleya-house, and, contrary to most albinos, it thrives better than the type.

C. bellatulum hybrids. — These hybrids are freer-growing, and more easily cultivated in glass-houses than are their parents. But it is necessary to bear in mind the characteristics of the parents, whether they thrive in a warm or intermediate temperature, whether they are impatient of water lodging in their growths, or require dense or moderate shade. Speaking generally, the hybrids should be afforded a temperature of 65° to 70°; the light should not be very strong, nor the atmosphere clammy, but it should be moist. The leaves are very brittle, and must be handled with extreme care.

Dendrobium Phalænopsis, &c.—The various forms of this beautiful species, with D. bigibbum, D. Statterianum, D. undulatum, D. Goldei, D. Leeanum, and others of this section, are now growing freely, and need to be looked over frequently, so that as soon as roots are seen emerging from the base of the new growths, the necessary repotting or surfacing may be done. These Dendrobiums require all the light and heat of the East Indian-house, and should only be shaded for a few hours on very bright days. Plant them in small pans, using a very small quantity of peat and sphagnum-moss. When rooting freely, copious applications of water are necessary, and the syringe should be used amongst them morning and afternoon if evaporation be rapid.

THE APIARY.

By Expert.

Building up Stocks in Spring. — It is not too soon to begin preparing for the early honey season, which is now close at hand. We have already had encouraging reports of carefully-attended-to hives being "full of bees and brood," on the strength of which condition more than one of our readers located in Kent have already made up their minds to enter honey of 1899 for the "Royal" Show at Maidstone in June next. It is certainly promising to hear, as we did on the 20th ult., of hives found on inspection "with bees between every one of the ten frames;" but we fear this will be rather the exception than the rule. However, it is now quite time to set about doing what we can to get the bees forward by careful and judicious feeding wherever there is the slightest suspicion regarding scarcity of stores. The incoming of food in spring means increase of brood in the hives, and although we do not advocate entire reliance on candy-feeding at this season, personal experience has proved beyond doubt that the judicious giving of a cake or two of soft candy as a stimulative supplement to stores already in the hives is the best of all methods of brood-spreading, not only because of its increasing the brood, but of avoiding the too frequent mischief arising from parting frames of brood and the insertion of empty combs in their stead early in the season.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	May 22	Bank Holiday.
WEDNESDAY,	May 24	Linnean Society, Anniversary Meeting. Bath and West and Southern Counties Show at Exeter (5 days). York Florists' Exhibition of Tulips, &c.
FRIDAY,	May 26	Royal Botanic Society, Lecture.

SALES.

WEDNESDAY,	May 24	Clearance Sale of 60,000 Bedding and other Plants, at the High Street Nurseries, Crawley, by order of Mr. E. Yetman, by Protheroe & Morris.
THURSDAY,	May 25	Clearance Sale of Orchids, Stove and Greenhouse Plants, at The Gardens, Lower Cheam House, Sutton, by order of the Executors of the late N. L. Antrobus, Esq., by Protheroe & Morris.
FRIDAY,	May 26	Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period May 7 to May 13, 1899. Height above sea-level 24 feet.

Remarks.—The weather has been dull and dry, with variable cold winds. The only measurable quantity of rain which has fallen this month was on the 13th.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—56·4°.

Actual Temperatures:—

London.—*May* 17 (12 p.m.): Max. 56°; Min. 50°.

Provinces.—*May* 17 (6 p.m.): Max. 62°, Ipswich; Min. 48°, Hebrides.

Malcolm Dunn.

The unexpected death of Malcolm Dunn on Thursday, the 11th inst., at the age of 61 years, which it was our painful duty to have to record last week, as we were going to press, removes from among us one of the most prominent, conscientious, and energetic of our gardeners, one ever eager to give his aid in all matters connected with gardening in its practical aspects, or in its philanthropic connections.

He was in his usual health and vigour on Tuesday throughout the day, and it is thought that he caught cold in returning from a meeting in Dalkeith on Tuesday night. All that seems certainly known is, that on Wednesday morning he complained of feeling unwell, with acute internal pain. His medical adviser was at once summoned, and made several visits, remaining with him until an early hour on the following morning, when Mr. Dunn passed away.

Mr. Dunn, it is generally supposed, was a native of Crieff, being a son of a well-known coach-driver in the town and district. He was educated at the parish school in Crieff, and commenced his horticultural career by serving an apprenticeship in Strathallan Gardens, Perthshire, with the late Mr. Thomson. Subsequently, after removing to England, he was employed in Trentham Gardens, Staffordshire; and after spending some time in Messrs. Veitch's nursery, Chelsea, he was sent by the late Mr. Henderson, who was gardener at Trentham at the time (1860), to be foreman under Mr. J. W. Miller, one of the best Peach-growers of that day, and now gardener at Ruxley Lodge, Esher. This was at Eardiston House, the seat of Sir William Smith, Bart., Tenbury, Worcestershire. Leaving Mr. Miller, Malcolm Dunn was engaged as foreman at Sprotborough Hall, Yorkshire. In 1865 he was appointed to take charge of the gardens at Powerscourt, Lord Powerscourt's estate in Wicklow, then being improved and remodelled. Here Dunn, in conjunction with another gardener, carried out great alterations in the flower-garden and pleasure-grounds, planting Conifers extensively.

Dunn, previously known as a practical gardener of high repute, became more widely known by the successful manner in which he combated the Phylloxera vastatrix in the vineries of Lord Powerscourt. Complete and lengthened submersion of the borders was the method adopted, and where circumstances allow of its being done, it still continues to be the most efficacious method.

After a stay of several years at Powerscourt, he was engaged by the Duke of Buccleuch as head gardener at Dalkeith Palace, in November, 1871, in succession to Mr. William Thomson, late of the Vineyard Nursery, Clovenfords, who had resigned.

As the successor to such great gardeners as McDonald, Charles McIntosh, and William Thomson, it is sufficient praise to say that Malcolm Dunn sustained the high level of their reputation at Dalkeith.

A considerable alteration that he effected at Dalkeith was hardly completed before his death. This was the substitution, by Messrs. Mackenzie & Moncur, of three powerful tubular steel boilers for about twenty smaller ones, that were required to heat the glass-houses. In ordinary weather two of these will be sufficient. The saving in labour and fuel thus obtained is enormous. In fuel, for instance, the quantity saved daily is three and a half tons. The flues have been so constructed that there is no draught beyond the boilers, and consequently there is no waste.

As a landscape-gardener he possessed good taste, and an eye which detected in a moment the smallest mistake. He had an extensive knowledge of plants in regard to nomenclature, habits, and habitat, and could advise what was best suited to any given locality.

As a pomologist he had an extensive knowledge of varieties; and the correctness of the nursery fruit catalogues of the present day is largely due to his advice, and to the prominent part he took in assisting at and in the promotion of the several fruit conferences of the last twenty-five years.

His labours in connection with the Scottish Arboricultural Society, of which he became a member twenty-five years ago, were soon made evident in his strenuous efforts to make it a powerful factor in advancing the science of forestry, formerly much neglected. He was an enthusiastic supporter of the scheme for a Forestry School for Scotland. Mr. Dunn took a leading part in the establishment and successful carrying through of the great forestry exhibition in Edinburgh in 1884, and was always present at the excursions of the Scottish Arboricultural Society, whether at home or abroad. He was looking forward to a visit to the great French exhibition, and the French woods and forests, in the year 1900.

He was on the Council of the Royal Caledonian Horticultural Society; and his services to the Scottish Horticultural Association are well known. The last-named Association was instituted in Edinburgh in 1877, and Dunn filled the office of President for the first five years.

To the Conifer Congress, held at Chiswick in the autumn of 1891, Dunn lent unstinted aid, collecting statistics from Scottish sources not easily accessible to others, and himself supplying an extensive collection of specimens. To him we also were indebted for details concerning the many trees planted by Her Majesty, and which were published at the time of the second Jubilee festivities.

As regards his contributions to our columns, they were more numerous than might be thought—such was his retiring disposition that he persistently shrank from attaching his signature to his contributions, and it was only rarely that we could induce him to sign his name to his communications. This reticence arose not only from natural modesty, but from his earnest desire to be accurate even in minor details. No matter whether a statement was in all probability substantially true, if he could not himself verify it, he would not lend his name to it. This striving for accuracy made him a keen but just, and never unkindly critic of others who were, and are, compelled by circumstances, to write under pressure.

Qualities such as these rendered him most valuable as a judge at exhibitions, and as a general counsellor and adviser in matters horticultural. His published communications in these columns are relatively few in comparison to the critical and wise counsels with which we were privately favoured. One communication, which must have been the last ever penned by him, appears in our issue to-day. Indeed, to us his loss is a severe one, as we have had occasion for many years to value his assistance, and his conscientious impartial judgments on men and things.

Mr. Dunn was elected a Veitch Medallist in 1896, when the other persons so recognised were F. W. Burbidge, H. L. de Vilmorin, and Professor Sargent; and he was the recipient of the Niel Prize in horticulture. His reputation as a gardener led also to his nomination by the Royal Horticultural Society as a Victoria Medallist. His death forms the first break in the ranks of that august body, and it will be by no means easy to fill his place.

Mr. Dunn having never married, had fewer home ties than most men, but his sympathies, time, and money, were unreservedly given to horticulture. His house was an open one to every gardener, young or old, that sought his aid or advice, and whether an applicant at Dalkeith was a mature gardener or an apprentice, if he held proper and sufficient testimonials, he was certain to obtain the active help of Malcolm Dunn. Such invaluable assistance, given in a variety of ways, was not afforded without pecuniary loss to the deceased, who was never the least concerned to save money, and who has probably died a comparatively poor man.

Though emphatically a Scottish gardener of the best type, his was no provincial patriotism. His training and his experience had been gained in each of the three kingdoms, and his sympathies were wide in proportion. He extended the same aid and support to the metropolitan organisations that he did to those north of the Tweed, and was, perhaps, almost as well known in London as in Edinburgh, which is saying a great deal. He took a warm interest in the Gardeners' Orphan Fund, the Gardeners' Benevolent Institution, and other garden charities.

The deceased was interred at Dalkeith cemetery on Saturday last in the presence of a large and sympathetic gathering. An extraordinary coincidence in connection with Mr. Dunn's death was the decease of his stepmother upon the same day, at King Street, Crieff. She was seventy-eight years of age, and was observed to fall while walking in her garden.

YORKSHIRE NATURALISTS' UNION. — The 143rd meeting will be held at Dent, for the investigation of the valley of the Dee, the northern slopes of Whernside, Gragreth, Holme Fell, &c., on Whit Monday, May 22, 1899. The Hon. Secretary, W. DENISON ROEBUCK, F.L.S., 259, Hyde Park Road, Leeds, will furnish all particulars on application.

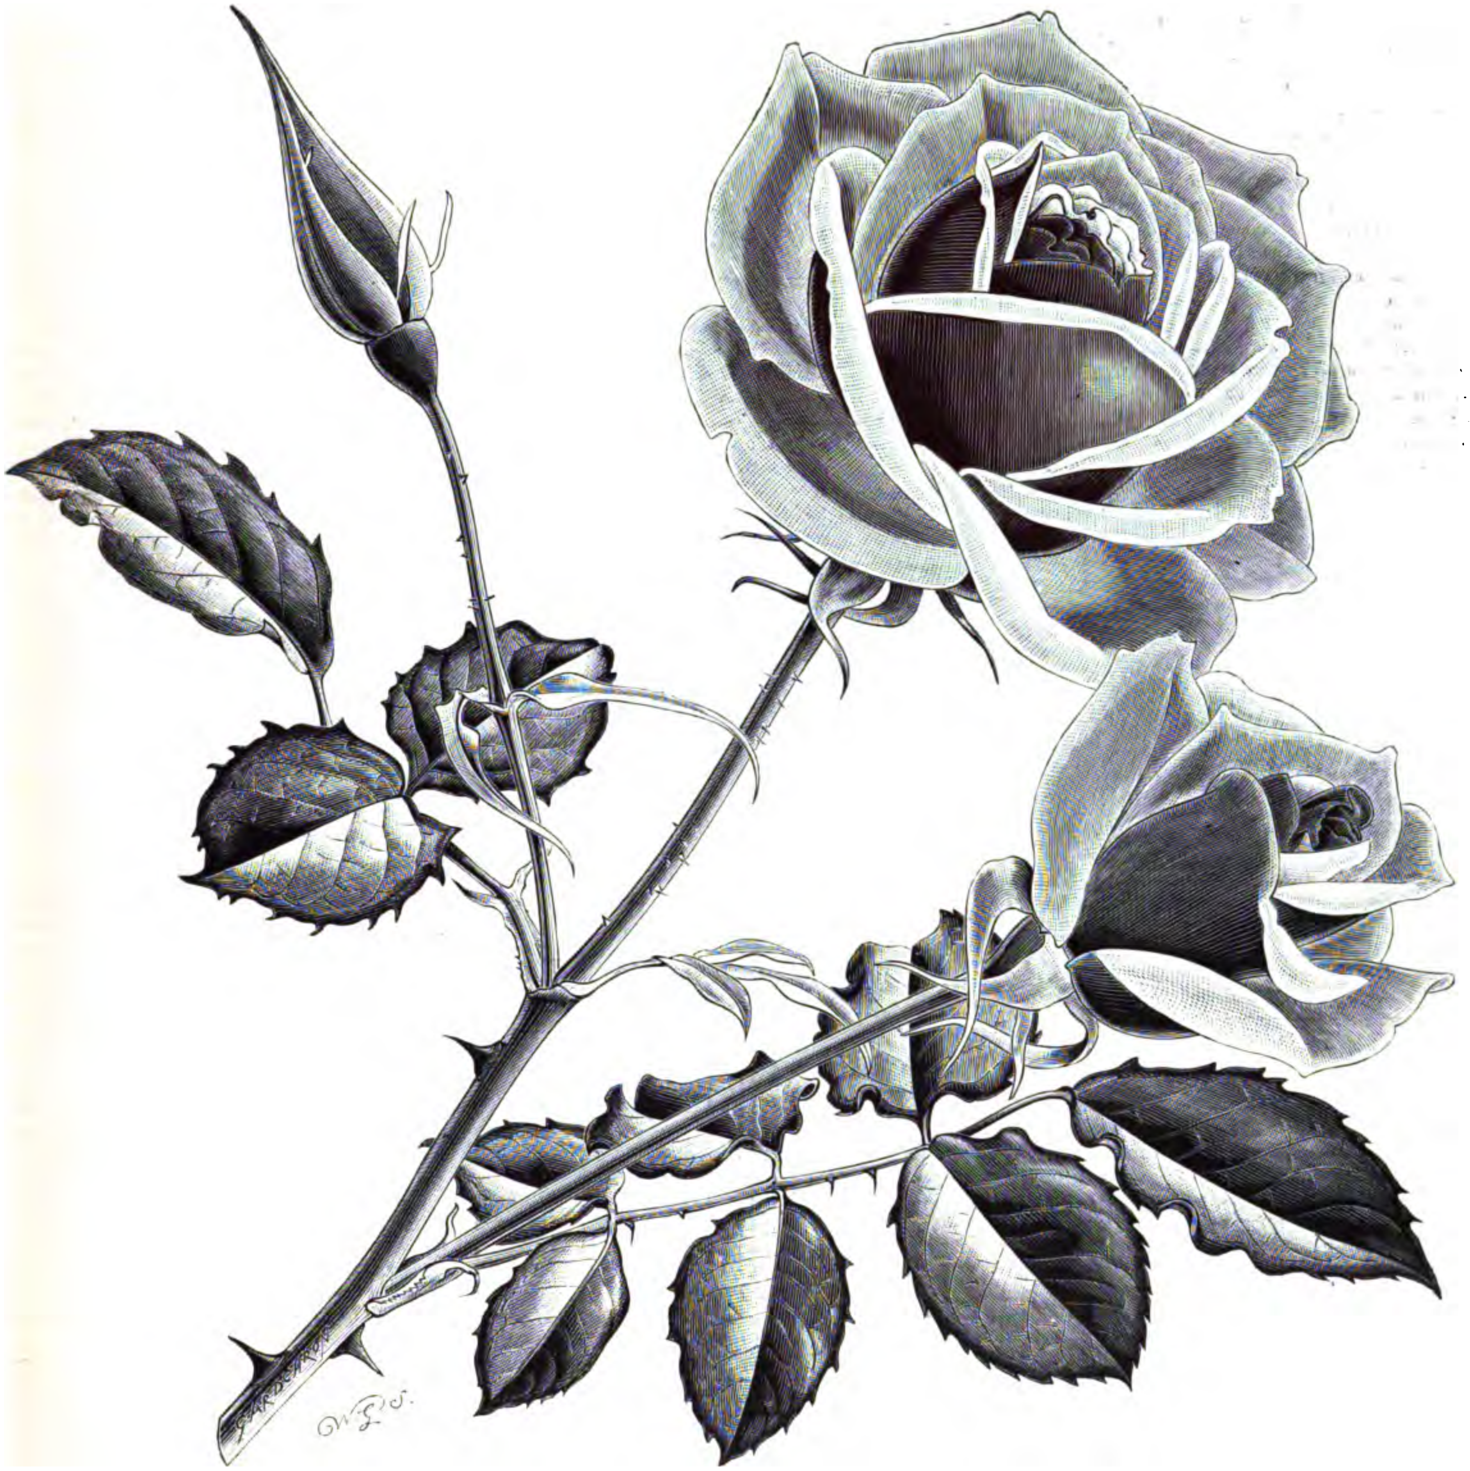

FIG. 117.—TEA ROSE "SUNRISE": COLOUR COPPERY-RED AND YELLOW. (SEE P. 324.)

A BUNCH OF TULIPS.—Mr. W. B. HARTLAND, of Cork, has sent us a bunch of Tulips of great variety and purity of colour. Among them are T. Didieri var. alba, with flower-segments 2⅜ inches long, oblong-pointed, creamy-white. The inner segments are broad and slightly notched.

Picotee has outer creamy-white segments, broad at the base, and gradually tapering to an acute point. The edges are marked by a very narrow pinkish-line, which has suggested the name.

Ixioides has segments tapering to both ends, and of a canary-yellow colour with a deep purplish-black blotch at the base.

Columbus has broadly oblong segments, tapering to each end with a yellow ground, feathered and flamed with crimson; eye yellow.

Fawn has flowers of relatively small size, the segments being 2¼ inches long, oblong, rounded at both ends; inner segments of the same size and form, and fawn-coloured flushed with pink, and with a yellow blotch at the base—a peculiarly beautiful flower.

Fairy Queen has the flower-segments nearly 3 inches long, tapering to the base, rounded at the apex; yellow at the margins, pale lilac in the centre, a curious combination, but nevertheless a beautiful one from the softness and delicacy of the tints.

John Ruskin is very similar, but the lilac tint is more pronounced whilst the yellow is paler. But for the flush of yellow the flower resembles in colour that of Magnolia Soulangeana. There are various others, some self-coloured orange-crimson; others white, feathered and flamed with rosy-crimson, but unfortunately the labels were displaced, and we fear to misname them.

KIND AND VARIETY.—The following letter was the last we received from Mr. DUNN. We received it only a day or two before his death: "In the new edition, or 1899 Code of *Rules for Judging*, issued by the Royal Horticultural Society, there appears under 'General Rules,' on p. 6, a lengthy definition of the use of the words 'kind' and 'variety,' for exhibition purposes. The application of these terms is shown by easily understood examples, and when exhibitors know the correct meaning of 'kind' and 'variety' it will save much unseemly wrangling at flower shows. All reasonable people will cordially approve of this attempt to solve a troublesome point; but surely the Royal Horticultural Society has been mixing its metaphors in the following quotation, which appears in the middle of paragraph 3. 'As a general rule, for the purpose of exhibiting, all natural *genera* are *kinds*, and all variations within a genus are *varieties*.' This clearly defines the terms 'genera' and 'kinds' to be *synonymous!* and as 'all variations within a genus,' according to this 'General Rule,' are in future to be treated as 'varieties,' the time-honoured terms of *genera* and *species*, hitherto in vogue among practical horticulturists, as well as botanical scientists, must, as a matter of course, disappear from horticultural prize schedules. If that is the intention it is hard to see where the necessity arose for the invention of the new terms and their use, in the sense of the words quoted above, will not diminish the risk of misunderstandings at horticultural exhibitions. Far better would it be to retain the old and well-understood terms of *genus* and *species*, and use the words 'kinds' and 'variety' in the way they have hitherto been employed, to distinguish the divisions and subdivisions of a species. *North Briton, May* 6."

ROSE SHOW AND CONGRESS OF GERMAN ROSE GROWERS AT STUTGARD.—This important event will take place in the Concert Hall of Stutgard from June 16 to 18 next, the Congress being held on the first day. Exhibition objects have to be delivered not later than 10 P.M., June 15, and cut blooms, bouquets, &c., on June 16, not later than 8 A.M. We note a class in which twenty-four varieties of some of our finest Roses are required to be shown to the number of ten blooms, and these furnished with long stalks.

THE FLOWERING OF PEACHES, NECTARINES, AND APRICOTS.—It is a matter of common remark this year that the fruit-trees on south walls and in glass-houses are not showing so much bloom as the conditions prevailing last autumn in this country would warrant us in supposing would have been the case. It is the opinion of many good gardeners that this failure is to be traced to the excessive heat, bright sunshine, and general lack of moisture characteristic of the summer and autumn of last year. The same lack of bloom occurred in Lilac prepared for forcing, as was noticed recently in these pages. The ill effects of weather conditions such as those experienced in 1898 could be in great measure averted by gardeners employing Bamboo or lath-blinds, or even double and treble fish-netting over the trees growing on sunny aspects, letting them down about 11 A.M. and taking them off about 2.30, and following out the practice on hot days only during the months of August and September. In conjunction with this shading of the trees, the borders should be kept in a fairly moist condition.

SPRAYING AND WASHING HOP-BINE, FRUIT-TREES, AND BUSHES.—A new and improved system for washing Hop and fruit-trees from blight and insect-pests has just been tested on some large fruit plantations, with results entirely satisfactory. It is one that has been introduced by Messrs. MERRYWEATHER & SONS, and is an advance upon anything that has yet been done in this line. A portable steam pumping-engine of the firm's well-known "Valiant" type is employed to pump the specially-prepared wash from the tank, and deliver it through lengths of iron pipe or flexible hose to several points, from which branches are taken, and suitable outlets and valves provided. As many as twenty-four powerful jets can be utilised at one time, and the blighted foliage thoroughly and cheaply cleansed. The first trial took place at the establishment of Mr. BEST, Suckley, Worcester, and spray was thrown well over the tops of Plum-trees more than 20 feet in height. Mr. BEST expressed himself as being quite satisfied with the way in which the plant did its work. The next trial was on the Toddington Orchard Co.'s plantation, under the supervision of Mr. C. D. WISE, the managing director, employing an engine of similar size and power. Here the wash was pumped through a pipe 500 yards in length (the pipe was 1½ inch), up a rise of 150 feet, with complete success. The application to Gooseberry-bushes was also made, the spraying being effected by a spreading nozzle. Mr. WISE and the other gentlemen present expressed their appreciation of the efficient manner in which the engine did its work. The third trial was held at Mr. ISAAC READER'S plantations at Paddock Wood. Here also all the tests were quite satisfactory, powerful jets being delivered through 1600 feet of piping. Mr. READER expressed his high approval of the system, and remarked that the plant was what had been wanted for many years, and that it was impossible to spray large trees by any other method. The apparatus is readily portable, two men being well able to wheel the engine, boiler, and furnace to any desired point. The engine can be made to serve as a fire-engine, and by throwing the pump out of gear it is available for driving farming or other machinery, and altogether forms a very valuable addition to any large plantation, combining cheapness in first cost with economy and efficiency in working. Another important feature is the arrangement of the suction-pipes so as to draw its supply of water and chemical from separate tanks in the required proportion.

THE EDINBURGH SEED TRADE—A PRESENTATION.—A smoking concert was held on the 12th inst. in the West End Café, 129, Princes Street, under the presidency of M. PETER DREW, at which Mr. ALEXANDER CHALMERS, the secretary for the trade annual gathering, was presented, on the occasion of his wedding, with a marble clock, and a massive gold albert, as a wedding gift; also a gold bracelet and brooch, set with diamonds and pearls, for his affianced bride. These were accompanied by, an illuminated address, containing the names of all the subscribers.

PRESENTATION TO MR. J. WALLIS.—A few weeks ago we announced that the friends of Mr. J. WALLIS, who has recently left Keele Hall Gardens, Staffordshire, after twenty years of service there, determined to present him with a testimonial as an expression of their esteem. The presentation was made on the 9th inst., and was accompanied by a cheque. Mr. WALLIS much appreciates the kindness of his gardening friends in this matter, but is unable to thank the subscribers individually.

METROPOLITAN PARKS AND OPEN SPACES.—At a meeting on Tuesday of the London County Council, the report of the Parks and Open Spaces Committee, recommending that £3000 should be contributed towards the sum required for the purchase of the Dollis Hill Estate for the use of the public, was agreed to without a division. This charming rural spot may be described as having for years been the "Saturday to Monday resort" of Mr. GLADSTONE. The place will probably be named Gladstone Park, though possibly the old name would be in harmony with the nature of the surroundings, and their association with the illustrious statesman. It may be noted that at the same meeting plans were approved for a large addition to the industrial dwellings of the metropolis in this instance, on the Millbank estate, near the Tate Gallery. It is to be hoped that some space may be found for a little grass, with specimen trees, and seats. These would be greatly appreciated by all who can value the moral and physical advantages of bright and roomy dwellings.

OCHTERTYRE ESTATE, PERTHSHIRE.—On May 14 a presentation was made by the *employés* upon the Scottish estate to Mr. DAVID KEATH MURRAY, who is leaving the district, and retiring from the position of factor. Mr. MURRAY is a brother of the proprietor, Sir P. K. MURRAY.

THE LIZARD ORCHID.—A valuable and interesting floral discovery has been made by the authorities at the Kent and Sussex Agricultural College at Wye, near Ashford, Kent. For forty years the Lizard Orchid has been lost to the British flora, but it has been re-discovered on the Kentish downs, where fifteen out of the twenty varieties of British Orchids have been found. We greatly regret that the Wye authorities have published the fact.

A CHARMING JAPANESE CHERRY.—We congratulate Mr. JAS. H. VEITCH upon the distinct and beautiful variety of Cerasus Pseudo-Cerasus, shown at the Meeting of the Royal Horticultural Society on Tuesday last. This plant, which Mr. VEITCH found when visiting Japan a few years ago, is said to come into bloom three weeks later than the variety Watereri. It is very much deeper coloured than that variety, being a magenta shade of pink, and the foliage is more effective from its bronzy appearance. The plant will constitute another decided acquisition to our hardy flowering trees and shrubs.

MARRIAGE OF MR. P. JACKMAN.—On May 11, at Pyrford Church, Mr. PERCY JACKMAN was married to Miss BLANCHE SHEARS; a large company assembled at the church, and the costly and numerous presents bore testimony to the general esteem in which both parties were held. Mr. P. JACKMAN is the junior partner in the well-known Woking firm of nurserymen.

WARM WEATHER IN THE STATES.—On May 2, summer weather, with the thermometer above the eighties, had followed the recent Arctic spell. At Buffalo it was still warmer, 90° in the shade. Of course, vegetation has wonderfully advanced. There is general lamentation regarding the scarcity of Pansies, due to the severe frosts without snow. One man, we read, planted 140,000 and lost 80,000.

CHESTNUTS.—Our contemporary, *American Gardening*, for April 22 last, contains an interesting article by G. HAROLD POWER, being the fourth in a series upon Commercial Chestnut culture. It is pointed out that European and American varieties derived from them will require immense improvement before they are of much commercial value. Alpha, a Japanese variety, sells sometimes for 12 dols. per bushel in the second week in September. A list of twenty-eight varieties, Japanese, European, and selected, is given, together with short descriptive notes.

RICHMOND HORTICULTURAL SOCIETY.—We have received a schedule of prizes to be offered at the Annual Show, which takes place in the Old Deer Park on June 28. This is usually one of the best of the suburban exhibitions, and we have no doubt the forthcoming display will be equal to those that have preceded it.

TO ASCERTAIN IF A SOIL CONTAINS LIME.—If a teaspoonful of soil be stirred into a glass of water, to which a few drops of ammonia have been added, and the whole set aside for some hours, the liquid which remains at the top will be nearly colourless; but where lime and magnesia are lacking in a soil, the liquid has usually a dark brown or black appearance, the intensity of colour depending upon the amount of soil taken, and, of course, upon its need of lime.

◆

SOUTH AFRICAN NOTES.

JOUBERT PARK, JOHANNESBURG.

WHEN the writer first came here, Joubert Park was a flat, ploughed field, 17 acres in extent, and quite destitute of vegetation. Now, after six years labour, in face of many difficulties — frosts, droughts, floods, hail, locusts, and political troubles, the place begins to wear a finished look. A hedge of Cupressus macrocarpa was first planted right round next the fence; within this a shelter-belt of Eucalyptus globulus and E. viminalis, Acacias dealbata, melanoxylon and mollissima, and Pinus insignis, to break the fearful dust-storms. After these had got up some 10 feet, Oaks, Cypress, Junipers, Casuarinas, Thuias, and tender Eucalypti were planted. All grew well, and within this much-needed shelter the flower garden was laid out, and lawns laid down according to plan. A very large and varied collection of flowers, flowering plants, shrubs, and bulbs, was put out, not with uniform success, since very many were quite new to the country, and frost and drought proved too much for some.

In the middle of the Park a large fountain was erected three years ago, the base of which rests on rusticated stone, and the flat upper surface is decorated with patterns of black shale and white quartz crushed small. The water edge is planted with Montbretias, Arums, Sparaxis pendula, Iris Kæmpferi, and the old I. chinensis Phormium tenax, Tritomas in variety, and Schizostylis coccinea, all of which do remarkably well. Last winter we had a very severe frost, water-taps in the open were burst, and long icicles remained for several days hanging from the upper basin, yet no losses were observed amongst the above named plants. Round the fountain-basin are four arches leading to the lawns; a bed of Tuberoses in the background. The arches are planted with Ipomœa pentaphylla, Physianthus albens, Clematis brachiata, English Honeysuckle, Solanum jasminoides, and Passiflora cœrulea, which have formed a dense covering.

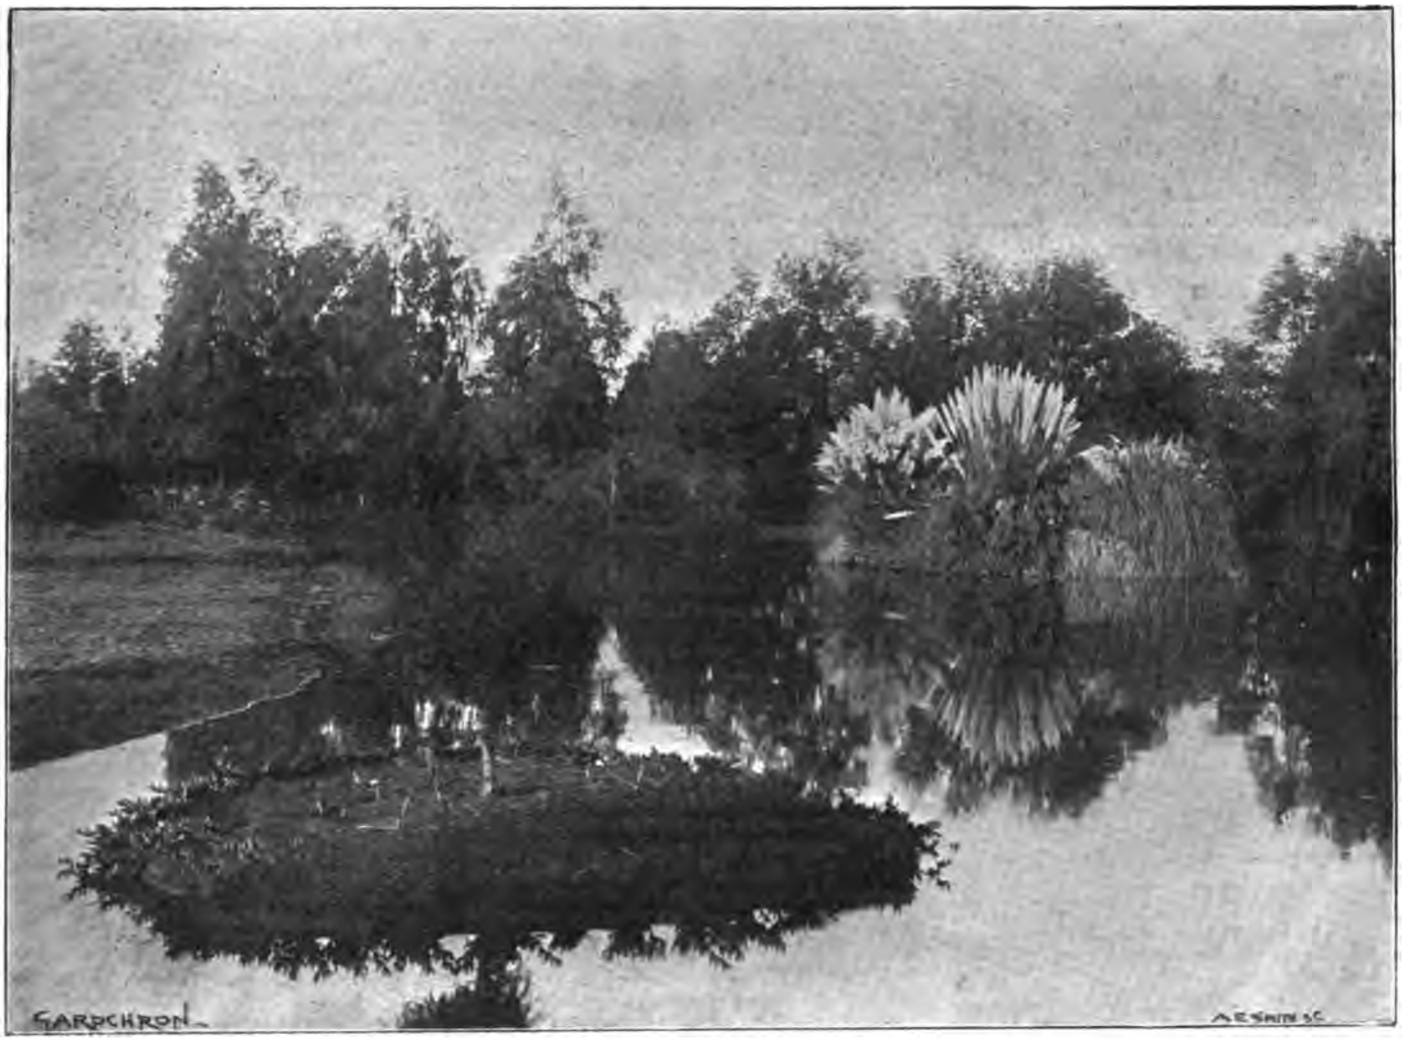

FIG. 118.—LAKE IN THE PUBLIC PARK, JOHANNESBURG, TRANSVAAL.

On the lower side of the park, a small lake has been formed (fig. 118), which is fed from the overflow of a fountain. The margins are planted with Weeping Willow, Hedychium Gardnerianum, Gunnera scabra, Coix lachryma, Crinum capense, Osmunda regalis, and small plants of Cyathea Dregei, as well as Agapanthus umbellatus, Arundo Donax, Lobelia cardinalis, and Gladiolus Papilio—all doing very well. In the lake we have Aponogeton distachyon, Nymphæa cœrulea, and some hardy hybrid Water-lilies flowering well. Nelumbium speciosum has been often raised from seed and planted out, but the young plants cannot withstand the first winter. On an island in the centre, Pampas Grass, Caladium esculentum, and Cannas, do very well. In the foreground is a small island with a tree of Taxodium distichum surrounded with Leichtlin's hybrid Tritomas, obtained from the generous raiser.

Two conservatories have been built, the smaller is 45 feet long by 18 and 15 feet high, heated by hotwater-pipes. A collection is grown of tropical Palms, Ferns, a few Orchids and flowering stove-plants. The larger house is 54 feet long by 24 feet broad and 20 feet high, and contains a fair collection of half hardy Tree-Ferns, Palms, and other plants which cannot be trusted outside, as Bamboos, Bougainvillea, Brugmansia, Cycads, Musa Ensete, &c. The whole upkeep of the Park is borne solely by the Town Council of Johannesburg, the annual vote being about £2000, of which £500 is for the water supplied by the Waterworks Company, at the very high rate of 3*s*. 6*d*. per 1000 gallons.

Situated as this town is, in the middle of a huge flat, treeless table-land—the High Veld—with no natural beauty, as woods, rivers, or mountains near, the Park is much frequented by the public. *R. W. Adlam, Curator, Joubert Park, Johannesburg, March* 9, 1899.

HOME CORRESPONDENCE.

THE LATE MR. M. DUNN, DALKEITH.—As a friend of over thirty years standing, I should deem it a privilege to publicly express my deep sense of the loss all horticulturists and arboriculturists alike have sustained by the demise of our dear friend. The late Mr. Dunn was born in the parish of Crail, in Fifeshire, where his father was a farmer. When comparatively young, his father removed to the neighbourhood of Perth, where at the parish school and academy he received his education. Having shown a predilection for horticulture, he was, at the age of fifteen, apprenticed as a gardener with the late Mr. Thomson, gardener at Strathallan Castle. On the completion of his apprenticeship, and after some time spent as journeyman, he moved south, and was fortunate in being admitted to the gardens at Trentham, then under the late Mr. Fleming, where he remained for some years, and where a similarity of temperament and energy with his master seemed to fully develop the latent enthusiasm of his nature. On leaving Trentham, he was in several good gardening places in England, notably at Sprotborough Hall, Doncaster, as foreman, and eventually was appointed head gardener at Erdiston, in Worcestershire. In 1865 he was appointed gardener to Viscount Powerscourt, at Powerscourt, co. Wicklow, where he had full scope for the exercise of his skill and energy in conducting extensive improvements in the gardens and grounds of that princely residence. The writer, having been appointed forester there at exactly the same time, had the benefit and pleasure of initiating a friendship with him which continued through life. Six years' close association with kindred tastes developed feelings of the warmest friendship and respect. From Powerscourt, Dunn was appointed, on the resignation of the late Mr. W. Thomson, as gardener at Dalkeith Palace in 1871. During the twenty-eight years that he was head gardener to the Duke of Buccleuch, and as he occupied what may be deemed the premier horticultural appointment in Scotland, he well sustained the traditions of that position. Having followed such men as Macdonald, McIntosh, and Thomson, he worthily maintained the reputation of Dalkeith, and none of his talented predecessors have done more for the advancement of horticulture and kindred sciences than he has done. Mr. Dunn as a practical gardener had few equals, and as a scientific gardener he took a premier place. His knowledge of botany, and kindred sciences, was extensive, and being possessed of a wonderful memory, and being a voracious reader he had the power of assimilating *ad libitum* every kind of professional literature as it appeared. With the science of forestry he was much identified; and having become a member of The Royal Scottish Arboricultural Society about twenty-five years ago, he very soon made his usual energy felt, in making it a powerful factor in promoting a science, before too much neglected. As a promoter and one of the executive committee of the first Forestry Exhibition in Edinburgh, he did much to secure its success, and yeoman's service in utilising it as a means towards enlisting greater interest in forestry. As one of the committee of the Conifer Conference he in no small degree contributed to the more extensive knowledge of this interesting family of plants, and their merits, as timber trees, or otherwise for this country. He was an enthusiastic supporter of the establishment of a Forest School for Scotland, and in the capacity of a vice-president of the above society worked hard with this object. Few who have had the privilege of attending the annual excursions of The Royal Scottish Arboricultural Society, will forget the care and foresight with which they were arranged, nor the energy and enthusiasm by which they were conducted by our departed friend. To the young and inquiring forester he was always ready to impart knowledge, and no trouble was too great if it helped to cast a light on any disputed question. As a patient preceptor to the young, a faithful and sound adviser to the old, gardeners and foresters alike have lost a devoted and disinterested friend, and cultural science generally one of its brightest ornaments. In his private relations Mr. Dunn was a steady, consistent, and warm friend, sterlingly honest, a determined enemy of humbug and sham. Yet, while warm in his devotion to those he admired, he would always excuse the errors of his less desirable friends, and he has left behind him few enemies, and many admiring and devoted friends, who now, alas! mourn his loss. *C. S. F.*

TOM-TITS AS ENEMIES OF THE HORTICULTURIST.—As this subject is attracting some amount of attention at this moment, it is well to mention that I alluded to it in connection with Peas in pod in this journal either in the year 1887 or 1890. I was then staying with a friend, a well-known entomologist, at his vicarage, not far from Wincanton, in Somersetshire. His Peas had suffered very much from the attacks of birds, which he suspected—and rightly, as was proved—were not sparrows. He noticed that the mischief was always done in the early morning, and determined to watch and find out the real depredators. So, concealing himself not far from the Peas about 5 A.M., he had most undoubted proof that two species of tom-tits were the culprits, the worst in point of numbers being the marsh-tit. I did not see them in the act, but I remarked that the *modus operandi* of the tits was different to that of sparrows. The latter tear and lacerate the pods in extracting the Peas; the former go to work much more neatly, and bore holes in the pods. It might be thought that the tits were really in search of the grub of the Pea-weevil, but both my friend and myself were fully convinced it was not so, for the Peas were to all intents and purposes free from grubs. As a lover of birds, and having the greatest respect for tits as horticulturist's benefactors, this came somewhat as a shock, but there was no getting away from the facts. *R. McLachlan.*

MANGO-TREE IN BLOOM.—I have a Mango-tree in bloom in my conservatory, and supposing such an occurrence a rare thing in England, I wish to make the fact known. The fruit was brought home from India about ten years ago, and the seed planted. This is the first time the tree has blossomed. It grows in a cool conservatory, with just sufficient heat in winter afforded as will keep the frost out. Can you tell me if the Mango has ever fruited in England? [Yes, often. ED.] *L. Elizabeth Smith, The Oaks, Emsworth, May* 15.

GARDENING NOT HEALTHY.—It seems that gardeners made in Germany (p. 301) are not healthy; but one's own personal experience, and the men we know and meet in the daily round, show that it is not so in this country. To begin at home, my own father was able to perform his duties as head-gardener at the age of eighty-four; and after he resigned he was doing a labourer's job at his home, and taking a chill after getting overheated, it turned to pneumonia, which caused his death at the age of eighty-six. He was hale and hearty up to that time; and we have many hale and hearty veterans in the ranks of British gardeners, and who, like my late father, take a keen interest in all that relates to good gardening, and old age has left them frosty, but kindly. From my observation, if a man is temperate in all things, I should say that gardening in England is a very healthy occupation. *R. M., Newbury.*

THE VIOLA OF THE FUTURE.—Those who would set about raising a batch of extra-early blooming bedding Violas should take stock of the early-blooming section of bedding Pansies, as these have invariably been earlier to bloom than have Violas proper, although the distinctions are comparatively small. The very earliest to flower is Blue King, and as an early blue-flowered bedder it has never been excelled. Were such varieties as True Blue, or others blue-tinted, crossed with Blue King, possibly the desired strain might result. Certainly much labour has been wasted by Viola-raisers in producing mere fancy or show varieties, all of which are summer-bloomers; whilst the production of very early bloomers has been greatly neglected. We want these hardy bedding plants now as badly as ever, for there seem to be so few which are suitable to furnish carpets to bulbs that bloom early, and simultaneously with the bulbs. The months when very early bloom is desired are March and April. In the following month plenty of plants, and especially Violas, flower freely. I do not advise as a "Florist" does, that old plants put out in October to bloom early should be trusted to do so all the summer; the result would be unsatisfactory. No plants increase easier from cuttings put out into a cold frame and near the glass in September than do Violas; and these rooted cuttings will, in the spring, make the best possible plants put out in May to keep flowering for several months. Then lifted in the autumn, the beds manured and dug, the plants together with bulbs replaced, the earliest bloom it is possible to obtain with present varieties is produced. Still, earlier-flowering forms are much needed. *A.*

THE PLANT COSTERS IN THE FARRINGDON ROAD.—Anyone issuing from Farringdon Road station, and walking along the Farringdon Road to the Holborn Viaduct, will note that in the line of costermonger's stalls those for the sale of plants greatly outnumber any others. Another fact can be noted, that more persons crowd about the plant-stalls than any others. A coster's barrow, when completely set out, contains a multitude of things. There are greenhouse plants in pots in large variety, many kinds of hardy perennials, Carnations, Pinks, Canterbury Bells and other Campanulas, Sweet William, Columbine, and so on, and boxes of cuttings and seedlings of apparently almost every plant that can make the garden gay in summer. Some have Lilies in pots, others dry bulbs of L. auratum. Every article is named and priced, and on the whole, the naming is creditable. The providing of these plants for the costers, seen also in so many other parts of London, must constitute a great industry, and they must be produced and sold cheaply to enable them to be offered at such small prices by the dealers. One wonders what becomes of the contents of the barrows by night, for the clearing out of such a varied stock by sale must occupy days. One of the most popular plants, judging from the number offered for sale, is Nicotiana affinis, which is labelled the "Sweet-scented Tobacco," and no doubt powerfully appeals to many in consequence. The roots of many of the seedlings in boxes must, one would think, suffer much through the waterings necessary when exposed on a barrow on a drying day, and probably the proportion of those which survive transplantation is small. Still, this widespread interest in the culture of plants is a feature that increases yearly, and is an encouraging sign of the times. *R. D.*

LAW NOTES.

POISONED GRAIN ON LAND.

AT the Oundle Petty Sessions, Northamptonshire, recently, a farmer, was summoned for that he did, between March 20 and April 2, 1899, lay, put, and place, or cause to be laid, put, or placed, poisoned grain on land at Warmington. Defendant pleaded guilty. Mr. Batten appeared for the prosecution. He said the Wheat was steeped in strychnine, and was strewed for a distance of about 130 yards on the top of the land. There was, he said, a rookery at Elton. This year sixty-seven rooks, one pigeon, and a number of other birds had been picked up poisoned. Defendant might have some excuse, but he took the farm with a knowledge of the rookery at Elton.

After Mr. Knight, public analyst, had given evidence, defendant informed the Bench that he told Mr. Crisp he had laid this poisoned Wheat to defend a crop of Oats, the seed for which cost him 21*s.* a bushel. He was prepared to swear that he did not put down the poisoned Wheat until the Sunday night after Good Friday. He only had a half-pint ready for rats, and he used a tea-cupful of it near these Oats. Defendant added: I do suffer a deal. I have known over 100 dozen rooks to be shot at this rookery, and 50 dozen or more of late years.

The Chairman said they fined defendant £7 and £2 2*s.* 6*d.* costs, including the analyst's fee. The act, he said, was of a very serious nature, for a poor person might pick up a pigeon, take it home, and cook it. He (the Chairman) did not hold with the killing of rooks; they did as much good as harm. The fine and costs amounted to £10 3*s.* 6*d.* *Agricultural Gazette, Monday, May* 15.

FRUIT GROWING IN KENT.[*]

HAVING glanced at the conditions that prevailed in the past, we arrive at the year 1869, when that period of agricultural depression set in, which has been a great factor in turning the minds of farmers and landowners to sources of revenue other than ordinary three or four course husbandry. The gardening press had for some time been dinning into the ears of the public that vast sums of money were leaving the country for the purchase of such hardy fruits as could be grown in Britain. The daily press caught the same spirit, whilst the agricultural papers took up the idea earnestly, but slowly. By degrees this idea became a fact, and those men who went in boldly for fruit-culture at that time have made fortunes; and many labouring men, who had plenty of hard work in them, began in a small way and extended on all sides as they accumulated capital. There was another factor which had to be reckoned with. The removal of the excise duties from hops and malt had so depressed prices that orchards were found to pay better on an average of years than Hops or Barley; and fruit trees were introduced in the Hop-gardens in order that when they reached a paying age the Hops might be grubbed and the land laid to grass, as before the introduction of foreign mutton and beef, live stock was as yet a safe investment for farmers. For, in a grass orchard, as an old hand once remarked to me, "We get three crops: mutton, wool, and fruit." The growth of soft fruit for the making of jam and preserves, bottling, &c., which had hitherto been a local business, now became a vast industry, and thousands of acres of poor woodland and thin arable lands were adapted to the culture of Strawberries and bush fruits in the Swanley and Cray districts of Kent. No small amount of their success in those parts is doubtless owing to the cheap manure which they procure from London, where the authorities very rightly decline to have it stored, and it is this fertilising agent more than the soil itself which has justly made the Swanley fruit a name all over the kingdom.

Fruit-culture then began to be taken up as a serious business, and every advantage of improved systems of culture was embraced. New kinds of fruits in each family were tested, and their suitability for market, when once known, caused them to be largely planted. The matter of pruning, which we take to be the crux of the Kent system, was carefully developed, and it was found that very much finer examples could be produced by severe pruning, while such fruit made the highest prices. Timely pruning, gathering of the crop at several pickings, with an extra top dressing of manure in summer, gave results never dreamed of before. Growers were not slow in following such evident sources of profit, while new and distant markets became available, as the Northern and Western Railway agents eagerly competed for this traffic; and so it came to pass that Strawberries (which are one of the most perishable fruits) could be gathered at Swanley, and put on rail to reach Glasgow and Edinburgh the same day in good order.

My remarks in this division have hitherto referred more to soft fruits (Currants, Raspberries, Cherries, and Strawberries), but attention was at the same time given to Plums and Apples and the hardier kinds of Pears, which soon proved themselves to pay handsomely for cultural care, while the introduction of the Paradise stock for grafting Apples upon, enabled growers to obtain crops from trees three or four years old in bush form. The fruit from such trees, by its proximity to the ground, and by the aid of reflected heat, possessed such beauty, size, and appearance, that even in years when a glut of fruit obtained, the Apples from the Paradise trees made a good paying price. In fact it pays a farmer to plant them on a fourteen years' lease. Instead of the old tall orchard standard trees, Plums planted as two year old trees, headed back low for half standards, became the rage, and gave a crop the fourth or fifth year, and by a combination of the plantation system with top fruit, very large returns were secured from a small acreage. A word as to the Paradise stock. It is a surface-rooting Apple found in the central Asian mountains, and was named Malus paradisica from its being discovered near the supposed region of the Garden of Eden. This variety, though a weakling by itself, gives great vigour to the Apple scions and buds placed upon it, and causes the trees to produce fruit (as before stated) much earlier than trees raised on the Crab Apple. Heavy crops are frequently obtained on two-year trees and have to be thinned out. All the sorts of Paradise Apples have this effect except the narrow-leaved French variety, which has such a restrictive action on the scion that it fails to make a paying tree, and unfortunately this fact has in the past caused the Apple trees on this stock to be condemned. Our best nurserymen are now well aware of this, and only use for stocks the broad-leaved varieties. In the Royal Horticultural Society trials at Chiswick, it was found that the Paradise Apple stocks that were not grafted gradually dwindled away, while those which had "taken," or been worked, formed handsome and fertile trees. It is by use of these Paradise stocks that nurserymen are able to supply examples in many cases capable of bearing fruit the first season after transplanting, as this Paradise stock produces such abundant surface-roots that the trees do not suffer on removal.

There is yet another factor that has assisted the culture of fruit in the past thirty years, viz., the introduction of steam for the purpose of clearing and deeply cultivating the soil, in many cases quite equalling trenching. The good work done by the Royal Horticultural Society through its publications, conferences, and exhibitions, has conferred a great benefit on the public by the introduction of novelties and the awarding of medals and certificates to the most deserving kinds. The gardening press has done loyal service in giving information, and the lectures and practical demonstrations by the County Council lecturers have brought home to the people the advantage of culture, and the rational use of preventative mixtures for blights, insects, &c.

While not agreeing with the American system of spraying with poisonous compounds (as Paris-green, and London-purple) for orchards and plantations, having regard to their dangerous character, yet the use of winter dressing of lime, soot, and soft soap, and sprays for insects when they appear in spring or summer, is very desirable. Many of our best growers spray as often as four times a year, both as a preventative and a cure, but a free use of manure, clean cultivation, and care to search regularly for insect blights in order to cure such before they spread, will render drastic measures unnecessary.

It would be well in this place to give the *modus operandi* in forming orchards and plantations as now practised by the best Kent growers. If an orchard be desired on what is now grass land, say Cherries, they are planted at 36 feet apart in rows; but in order to reap an earlier return, Plums are placed between the Cherries at 18 feet apart, as these commence to bear the fourth or fifth year, whereas Cherries are some eight or ten years before they pay to pick. In planting, the turf is removed or dug in, and holes about 3 feet over and 1½ feet deep, are made to receive the trees, which, after planting, are staked, and if cattle are allowed into the orchard they are protected (cradled) with chestnut pales, made square or triangular to keep the heads of the trees from the reach of the cattle. The Plums are pruned back the first year, but the Cherries are better not cut back until they have made a year's growth. Care is taken to keep grass from rooting in the 3 feet circle, as its presence and penetrating power would otherwise absorb all the moisture necessary for the young tree to establish itself. The orchard trees are summer and winter pruned, and shaped, or balanced for five or six years, until they are fitted to be grown on, with an occasional thinning of the main boughs, and the ties which attach the trees to the stakes are renewed also. In forming a plantation, a field or stretch of ground which has been previously prepared by a crop of Potatos, Peas, or Greens, is deeply stirred, and the standard or half-standard trees are placed in lines, say 15 feet apart, for Plums, small-growing Apples and Pears, and 18 to 24 feet for the larger kinds. These being planted, give the pattern for the bush fruit, which will then be introduced in long lines at 6 feet apart, so that horse-hoes can be used to keep the land clean, all the trees of a kind being planted in a block so that the fruit can be gathered at one time. I strongly recommend that all new orchards be raised in arable land, when for some years a handsome profit can be made from intermediate vegetable crops, Wallflowers, &c., the cultivation of which is of great benefit to orchard trees. In the culture of Strawberries it is usual to plant after some crop which has been highly manured. The plants are set in spring, or, if favourable, in autumn. An acre requires some 12,000 for a plant at 2 feet apart, 30 inches from row to row. An improved plan now obtains of planting on the square, as horse cultivation can then be used both ways, and thus hand labour is saved.

---

[*] Extracts from a paper by Mr. George Bunyard, Vice-President of the Fruit Committee of the Royal Horticultural Society, read before the Members of the Society of Arts on Wednesday, May 10, 1899, Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., in the chair.

The Kent Cob Nut is very extensively grown in Kent, where the largest-sized nuts are produced; being a hardy subject, not particular as to soil, many steep banks and stony patches of land that will not grow better fruits are planted with trees at 12 to 15 feet apart, and for some years until the Cobs require all the ground, vegetable crops or bush fruits are grown between them, which being highly manured help the Nuts to form trees. They begin to crop the third year; many old plantations are found with trees 100 years old, some 24 feet through, and not more than 6 feet high, as they are severely pruned to keep the trees in the form of an inverted umbrella with about 9 to 12 main branches, all coarse wood being pruned away, as it is from the young spray that the Nuts are produced. The female blossom appears in February, and the male catkins or polliniferous flowers are best left on (or at least a portion of them) until the blossom is set, say March, before the winter pruning is carried out. They are also pruned in August, taking out the strong "wands" which are used for packing, and the top surplus growth is then broken off. A good plantation will yield ½ ton to the acre, but we have had two or three good years (1896-7-8) when crops have reached to 2½ tons. Prices vary from 25s. to 60s. per 100 lbs. Standard Apples and Plums are often planted over them, and this gives a larger return per acre, but Cobs are best alone, though they succeed fairly well under trees. Cob Nuts will also flourish in good ground (soil), but that is usually reserved for choice fruits and too gross growth is not favourable to their cropping.

Insects.—To deal properly with the subject of injurious insects affecting fruit trees and bushes would require an evening by itself, and I can only here suggest that adequate manuring of the soil, burning all prunings and rubbish as soon as collected, combined with a winter washing of lime, soot, and soft soap on the older trees, will to a great extent check insect ravages. Spring and summer spraying will be necessary for red spider on Gooseberries, aphis in Plums and Damsons, and black aphis in Cherries as soon as any insects are observed; they are readily seen, as the leaves curl on being attacked. Special formulas are given in most fruit books, but the safest remedy for spraying is soft soap and quassia. Where winter moth is prevalent orchard trees must be grease-banded, care being taken to place a ring of grease-proof paper on the stems before greasing.

(*To be continued.*)

SOCIETIES.

ROYAL HORTICULTURAL.

MAY 16.—The meeting held on Tuesday last, in the Drill Hall, James Street, Westminster, immediately precedes the great Temple Show, and usually on such occasions the exhibits are rather fewer than above the average. This is partly true of the meeting under notice, for although the Hall was moderately well furnished with a miscellaneous collection of plants and flowers, there was not the abundance so frequently shown.

The ORCHID COMMITTEE recommended the awards of two First-class Certificates—one to a hybrid Phaius, P. × Phœbe, and the other to Odontoglossum Coradinei Mirabile. Also five Awards of Merit, all of which were to varieties of Odontoglossums.

An unusual number of Medals were awarded by the FLORAL COMMITTEE, but of Awards to novelties this Committee recommended two only. One of these was a First-class Certificate to a charming variety of Cerasus, collected by Mr. JAS. H. VEITCH in Japan; and an Award of Merit to a variety of Lathyrus splendens, shown by the Director of the Royal Gardens, Kew. Tulips were staged by Messrs. BARR & SONS, JAS. VEITCH & SONS, and HOGG & ROBERTSON, Dublin, the Irish collection again attracting much admiration. The hardy plant nurserymen contributed collections of plants in flower, but they complained that these plants are very backward in coming into bloom this season.

A fine specimen of Amherstia nobilis, from the Director of the Royal Gardens, Kew, was an object of great attraction.

The FRUIT COMMITTEE made no Awards to novelties, and beyond some very fine Strawberries, there were few exhibits. The late Mr. Malcolm Dunn, having been a member of this body for some years, a resolution was passed, regretting his unexpected decease, and giving expression to the committee's sense of the loss thus sustained. The lecture given in the afternoon was by the Rev. Professor Henslow, who spoke in an interesting manner upon some of the plants present in the Hall. Previous to this there were fifty-four new Fellows elected to the Society.

Floral Committee.

Present: Chas. E. Shea in the chair; and Messrs. Jno. Fraser, C. T. Druery, H. B. May, R. Dean, John Jennings, Jas. Hudson, J. F. McLeod, C. J. Salter, J. Fraser, James Walker, J. H. Barr, J. D. Pawle, George Gordon, R. H. Jenkins, D. B. Crane, Herbert J. Cutbush, Ed. Beckett, E. T. Cook, H. J. Jones, H. Turner, Geo. Paul, H. Selfe Leonard, Geo. Nicholson, and Ed. Mawley.

Messrs. W. PAUL & SON, Waltham Cross, Herts, made a very large exhibit of Roses in pots, which included well, flowered specimens of the extremely pale sulphur-tinted Tea variety Enchantress (figured in the *Gardeners' Chronicle*, Dec. 7, 1895, p. 673, and July 30, 1898, p. 89). Mdlle. Eugénie Verdier, Violet Bouyer, Corinna, Victor Verdier, Jeanne Dickson, and Gloire de Margottin were some varieties represented. In boxes were cut blooms of some of the newer Teas and hybrid Teas, as Empress Alexandra of Russia, Medea (a very pretty yellow Tea) Corinna, &c. (Silver Flora Medal).

Malmaison Carnation var. Princess May was shown by Mr. CHAS. TURNER, Royal Nurseries, Slough, who contributed a group of plants in 5 and 6-inch pots, all of them nicely flowered, and some of them showing the best shade of colour (Bronze Banksian Medal).

MARTIN R. SMITH., Hayes (gr., Mr. Blick), showed a rosy-red-coloured Carnation named Lady Hermione, but the variety gained no award.

Messrs. KELWAY & SON, Langport, Somerset, made a beautiful display with flowers of Tree Pæonies, most of them single-flowered, but including a few doubles. Some of the more choice were Countess Cadogan, white, marked prettily with Rose; Countess Crewe, and Mr. Jessop Hulton, a pure white one (Bronze Flora Medal).

Mr. H. B. MAY, Dyson's Road Nursery, Upper Edmonton, showed a group of Gymnogrammas, in the centre there being half-a dozen intensely-coloured plants of G. grandiceps superba, a capital variety of this well-known gold-coloured Fern. Quite of a different habit, but still extremely attractive, is G. alstoniæ, and G. a. superba is a more fascinating plant still, the characteristics of the type being in it more highly developed. One of the best of the white Gymnogrammas is G. peruviana argophylla, a pretty smooth-leaved Fern, that was shown in several fine specimens. G. Mayi, of the same type, is charming. G. chrysophylla, G. Wettenhalliana, G. schizophylla, G. pulcherrima, and others, were included among the thirty-six species and varieties in the collection (Silver Banksian Medal).

Messrs. R. & G. CUTHBERT, Southgate, made a more gorgeous display than ever with plants of Azalea × mollis and A. mollis hybrids. There were plants also of the A. rustica strain of the type known as Ghent Azaleas, the double-flowered forms of which are very pretty. Of the A. mollis section the following varieties were especially good: Comte de Quincey, Nicolas Beets, Emilie Liebig, Dr. Reichenbach, M. Desbois, &c., and of the Ghent varieties Gloria Mundi, Ariadne (white), Norma (red), Aida (pink), and Bartholo Lozari (yellow). There were about forty varieties in this group (Silver Flora Medal).

Messrs. WM. CUTBUSH & SONS, Highgate, also staged a fine lot of mollis and Ghent Azaleas, for which a Silver Banksian Medal was awarded.

Messrs. HOGG & ROBERTSON, 22, Mary Street, Dublin, again made a fine display of Tulips, the Darwin varieties and "Parrot" section being shown in great variety. Varieties of Tulipa Gesneriana, T. Billietiana (Didieri), and other species were wonderfully fine. The flowers in every section were of very unusual size, good substance, and brilliant colour (Silver-gilt Flora Medal).

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, contributed a group of flowers of bulbous plants. These were set up with much taste, and included considerable variety. There were Darwin, Parrot, and other Tulips, some of the later flowering Narcissus, and double Jonquils, Anemones, Allium Hermetti grandiflorum, Ixia crateroides, a very brilliant-flowered Ixia, and other varieties, Spanish Irises, strong spikes of Scilla peruviana, Tritonias, &c. A few plants, most of them annuals, in pots included Nemesia compacta bicolor, a pretty and small-flowered Nemesia; Clintoni pulchella, a dark blue flower with white centre, very effective for edging; Nycterinia selaginoides, Petunia Snowflake, a pretty white variety with single flowers; Linaria reticulata aureo-purpurea, &c. Messrs. VEITCH also exhibited a dozen plants in flower of Richardia Elliotiana; a charming tree Pæony with flowers of a salmon shade of rich rose, and plants in flower of Hydrangea Hortensia Mariesii (figured in a supplement to the *Gardeners' Chronicle*, May 28, 1898) (Silver Flora Medal).

Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, in collection of hardy flowering plants, included a few Auriculas, a considerable number of blooms of late Narcissi, some plants representing varieties of Primula Sieboldi, several species the Iberis, including I. Little Gem, profusely flowering at a height of 2 to 3 inches; Saxifragas, &c. (Silver Banksian Medal).

Messrs. PAUL & SON, Cheshunt, had groups of a number of choice hardy plants in pots. We noticed Geum Heldreichi, G. aureum, and G. miniatum; Viola canadensis, Tiarella cordifolia, the purple-flowered variety of Aubrietia named William Marshall, Trollius japonicus plenus, Phlox stellaria, several well-known forms of Iberis, &c. Also plants of their pretty and new Polyantha Rose Psyche (figured in a supplement to the *Gardeners' Chronicle*, May 7, 1898). The flowers are double, with a delicate pink centre (Silver Banksian Medal).

Messrs. BARR & SONS, King Street, Covent Garden, London, made a fine display with Narcissus flowers Darwin, Parrot, and garden varieties of Tulips; plants also of Trillium grandiflorum, one of the flowers being so much larger than the type as to suggest a varietal difference, but was probably an illustration of the effect due to cultivation. Scilla pyramidalis alba, and other Scillas, Nepeta hederacea variegata, &c., were noticed (Silver Flora Medal).

Messrs. GEO. JACKSON & SON, Woking, Surrey, had another collection of hardy plants in which could be seen the handsome Incarvillea Delavayi. The plant is perfectly hardy, and its Gesnera-like rosy-purple flowers are really lovely. Anemone sylvestris fl. pl., Daphne Cneorum major, Phlox canadensis, Gentiana verna, and many other species of hardy plants in flower were shown (Bronze Banksian Medal).

Mr. G. W. PIPER, Uckfield, Sussex, again exhibited a quantity of blooms of his new Tea Rose Sunrise, an illustration of which we reproduce on p. 319. Its uncommon shade of colour should make it a favourite.

From F. D. GODMAN, Esq., South Lodge, Fareham, were shown blooms of Irises Susiani, atrofusca, &c., and of a number of Rhododendrons, some of them from plants indoors, and others from the open ground; R. Aucklandii, R. blandfordiæfolium (from the open), R. Nuttalli, R. campanulatum, R. Thomsoni, &c., were included in this fine exhibit (Bronze Banksian Medal).

Mr. H. E. Gribble, gr to the Marquis of LONDONDERRY, Wynyard Park, Stockton-on-Tees, showed a plant in flower of Echium formosum. The flowers are curious by reason of the bright red stamens, that are much longer than the rest of the flower, which is blue.

From Mr. ED. S. TOWELL was shown a zonal Pelargonium, with the somewhat sensational name of "hybrid Cactus-flowered Geranium Fire Dragon." The flowers are vivid scarlet in colour, and some of the petals being much reflexed longitudinally, a bizarre-like appearance is given them.

Mr. Jas. Hudson, gr. to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, showed again several new continental (Bruant) varieties of Heliotrope of a robust, growing habit. They were recommended to be tested at Chiswick.

Amherstia nobilis, a fine spray of which came from the Director of the Royal Gardens, Kew, though a novelty to a great many persons, is an old plant, and was figured in the *Gardeners' Chronicle* as early as March 31, 1849, when it flowered for the first time in Britain in the gardens of Mrs. Lawrence, at Ealing Park. This leguminous plant makes a fine tree for the tropical-house, its carmine-rose coloured flowers being quite regal in appearance. The vexillum and two wings are tipped with yellow. It is a native of Burmah, and was named in compliment to Lord Amherst, a former Governor. A fine spray of Clianthus Dampieri (Sturt's Desert Pea) was also contributed from Kew.

AWARDS.

Cerasus Pseudo-Cerasus var. James H. Veitch.—A light purple variety of the Japanese Cherry, discovered by Mr. Jas. H. Veitch when visiting that country a few years ago. The flowers are about 2 inches across, and very pretty. It is nearest to the variety known as Watereri, but is very distinct, and deeper in colour than it, being a magenta shade of pink, and commences to flower three weeks later. The foliage is distinct also, and more decorative, being a pretty shade of bronze. The margins of the leaves are very finely toothed. From Messrs. JAS. VEITCH & SONS, Chelsea (First-class Certificate).

Lathyrus splendens var. Pride of California.—A handsome variety, with large velvety-like crimson flowers, shown by the Director of the Royal Gardens, Kew (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, H. M. Pollett, H. Ballantine, F. Sander, H. J. Chapman, J. Gabriel, W. H. Young, F. J. Thorne, E. Hill, H. T. Pitt, J. Colman, F. Mason, A. H. Smee, T. B. Haywood, and Sydney Courtauld.

As usual at the meeting immediately preceding the Temple Show, there was a rather small number of entries. Baron Sir H. SCHRODER (gr., Mr. H. Ballantine), staged a small group of marvellously fine varieties of Odontoglossums, together with an inflorescence of the superb Lælio-Cattleya × Digbyano-Mossiæ, with a fringed lip. An award of a Silver Flora Medal was made for the collection. The Odontoglossums were O. luteo-purpureum sceptrum, The Dell variety, and O. × Coradinei mirabile; O. triumphans, The Dell variety, a noble flower, with the lower half of the petals and lip of pure white, and the margins of a yellow colour. The petals were marked with a broad band of brown across the middle, and some small reddish spots. The sepals were yellow-excepting about two-thirds of their length next the column, which was banded with brown. O. × Andersonianum superbum, a grand form, with white flowers, bearing dark reddish-purple markings; and the pleasing red-flowered Dendrobium sanguineum.

Messrs. Jas. Veitch & Sons, Chelsea, showed the group of the day. Among the hybrids were the remarkable new Lælio-Cattleya × Hyeana (L. purpurata and C. Lawrenceana), a pretty flower, partaking much of the characteristics of the seed-parent. The sepals and petals were light lilac; base of the lip yellow with narrow red lines, the showy front portion being different shades of purple; Selenipedium × macrochilum giganteum (× grande and caudatum Lindeni), a singular looking and effective hybrid possessing creamy-white flowers veined with Indian yellow, and having elongated petals as in S. caudatum, one of the flowers on the plant shown having a third elongated segment in the position of the dorsal sepal; Epi-Cattleya × radicato-Bowringiana, the singular cross between Epidendrum radicans and Cattleya Bowringiana. The inflorescence bore four of its remarkable lilac-purple flowers, the labellums veined with dark purple; L.-C. × Zephyra (L. xanthina and C. Mendeli); varieties of L.-C. × Ascania (L. xanthina × C. Mossiæ); the pretty pale yellow spotted with crimson Spathoglottis × aureo-Veillardi; some splendid plants of the graceful Oncidium phymatochilum, good examples of O. sarcodes, O. concolor, O. ampliatum, fine forms of Cattleya Mendeli, and C. Mossiæ, C. intermedia, and others; a fine series of varieties of Odontoglossum crispum, both white and spotted varieties; a well-bloomed specimen of the singular-looking Cypripedium Mastersianum, and other Cypripediums; Epidendrum xanthinum, E. × O'Brienianum, E. × elegantulum, and its unspotted variety, luteum; Dendrobium atroviolaceum; the orange-scarlet D. subelausum, which is said to succeed best in a tolerably cool house; Lælia purpurata, L.-C. × Latona, L.-C. × Pallas, the brilliant deep scarlet-coloured Epiphronitis × Veitchi, and various good Masdevallias, &c. (Silver Flora Medal).

Jeremiah Colman, Esq., Gatton Park, Surrey (gr., Mr. King), secured a Silver Banksian Medal for a very pretty group of good plants, the centre one being a fine specimen of Lælia purpurata, with white sepals and petals, and very bright light purple lip. With it were good forms of Cattleya Mendeli, C. Skinneri, Odontoglossum crispum, O. Halli, O. luteo-purpureum, O. cordatum, O. Rossii, O. cirrosum, Epiphronitis × Veitchi, Sophronitis grandiflora, a good rose-coloured Miltonia vexillaria, Masdevallia Veitchi, Dendrobium atroviolaceum, Lycaste Skinneri alba, Cymbidium × eburneo-Lowianum, &c.

Walter C. Walker, Esq., Winchmore Hill (gr., Mr. Geo. Cragg), showed a good example of Cattleya Walkeriana nobilior, with a four-flowered inflorescence.

Messrs. Hugh Low & Co. showed Odontoglossum × Enfieldiense, a bright-coloured, medium-size flower.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr., Mr. J. Davis), showed Cattleya Mendeli "J. Gurney Fowler," a grand flower, of good size, having white sepals and petals, which are tinged with rose, the petals very broad, with a rosy-crimson feather on their outer portions, and the lip-front being of a bright rose-purple. The flowers were only just expanding, and not therefore at their best.

T. B. Haywood, Esq., Woodhatch Lodge, Reigate (gr., Mr. C. J. Salter), showed Masdevallia Veitchi grandiflora taken from the original stock.

Malcolm S. Cooke, Esq., Tankerville, Kingston Hill (gr., Mr. Buckell), showed a pretty spotted form of Odontoglossum crispum, with a very fine branched spike.

AWARDS.

Phaius × Phœbe (Sanderianus × Humbloti), from Norman C. Cookson, Esq., Oakwood, Wylam, Northumberland (gr., Mr. Wm. Murray). The finest of the many beautiful Phaius raised by Mr. Cookson, surpassing even the handsome P. × Cooksoniæ (grandifolium × Humbloti), especially in its much larger flowers. The broad sepals and petals nearly equal in size, were pale pink, tinged with nankeen-yellow, except the margins. Lip very broad, yellow at the base, with dark red lines in the centre, the medium area bearing a callus of fine orange-coloured ridges. The well-displayed front portion of the lip was light rose, with dark rose-coloured veining (First-class Certificate).

Odontoglossum crispum "Purity," from T. B. Haywood, Esq., Woodhatch Lodge, Reigate, a grand pure white form, 4½ inches across, and well proportioned. Crest chrome-yellow (Award of Merit).

Odontoglossum crispum "Raymond Crawshay," from De B. Crawshay, Esq., Rosefield, Sevenoaks, a fine form, worthy to take a place in the front rank of spotted crispums. The base of the flower is of that purple-tinted class which Professor Reichenbach originally designated "fastuosum," the petals being finely fringed. The petals bore one to three peculiarly bright orange-tinted red blotches, and the sepals a cluster of more or less confluent blotches of a similar unusual tint. Lip white, with yellow crest, and few light brown markings (Award of Merit).

Odontoglossum × Coradinei mirabile, from Baron Sir H. Schroder. This is the plant originally illustrated in the *Gardeners' Chronicle* as O. crispum mirabile, and on whose obscure origin we at the time commented. It seems to be a second crossing of O. crispum with O. × Coradinei, or *vice versâ*. The rather narrow segments bore very distinct large brown blotches (First-class Certificate).

Odontoglossum luteo-purpureum sceptrum, "The Dell" variety, from Baron Sir H. Schroder. A splendid form of the typical O. l.-p. sceptrum, but with very large and richly-spotted flowers (Award of Merit).

Odontoglossum polyxanthum, "Gatton Park" variety, from Jeremiah Colman, Gatton Park. One of the largest and best forms of the species. Flowers very bright yellow, heavily blotched with chestnut-brown (Award of Merit).

Odontoglossum × Andersonianum giganteum, from Messrs. Hugh Low & Co., of Bush Hill Park, Enfield. One of the largest and finest of the numerous varieties of O. × Andersonianum. Flowers 4 inches across the petals, and 4½ inches across the sepals. Flower French-white, with many red-brown spots on the sepals, and fewer and smaller spots of a similar colour on the middles of the petals (Award of Merit).

Fruit Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. W. Wilks, Jos. Cheal, W. Poupart, A. F. Barron, A. H. Pearson, J. Wright, Alex. Dean, S. Mortimer, J. W. Bates, Geo. Wythes, F. Q. Lane, H. Balderson, Jas. Smith, Geo. Thos. Miles, Geo. Norman, Robt. Fife, and M. Gleeson.

THE LATE MR. MALCOLM DUNN.

The Rev. W. Wilks, M.A., proposed, and Mr. Jno. Wright seconded, the following resolution:—"The Fruit Committee of the Royal Horticultural Society has heard with great regret of the sudden death of Mr. Malcolm Dunn, for many years a member of their committee; and whilst recording the loss they themselves feel, they also desire to express their deepest sympathy with the immediate friends of Mr. Dunn." The resolution was carried unanimously.

Mammoth Strawberries were exhibited by Mr. A. Bishop, Hile Crish, Market Harboro; Mr. J. W. Miller, gr. to Lord Foley, Ruxley Lodge, Claygate; and Mr. C. J. Salter, gr. to T. B. Haywood, Esq., Woodhatch Lodge, Reigate. The largest fruits were those from Mr. Salter, who had fruits of Royal Sovereign similar to berries of this variety we have seen in former years from Mr. Norman, of Hatfield Gardens (a Cultural Commendation was awarded). Mr. Miller's fruits of the same variety were truer to type perhaps in the tapering form, but they were rather less in size (Vote of Thanks).

Those from Mr. A. Bishop were of the varieties Monarch and Leader, the berries of Monarch being exceptionally large and fine (Vote of Thanks).

Mr. Jas. Hudson, gr. to Leopold de Rothschild, Esq., Gunnersbury House, Acton, showed several trees in pots of Cherry Guigne d'Annoncay, a black-fruited variety. The Cherries were just ripe, and may be said to be very early.

From Messrs. T. Rivers & Son, Sawbridgeworth, were shown two dozen fine fruits of their new early Nectarine named Cardinal. The trees from which these fruits had been gathered were cultivated in pots, and were started on December 23.

Messrs. Jas. Carter & Co., High Holborn, exhibited very fine roots of what is undoubtedly a good early white long-rooted Turnip. The same variety, it appears, has been shown under another name, or an Award of Merit would probably have been made in its favour. However, the variety will be tested at Chiswick.

A free cropping Tomato named Hepper's Goliath was shown by T. B. Haywood, Esq. (gr., Mr. Salter).

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT.

May 8.—The monthly meeting was held at Sandown on the above date, Dr. J. Groves, B.A., J.P., in the chair.

Mr. S. Heaton, secretary, gave a lecture on "Horticultural Subjects," which was illustrated by a large number of lantern slides, kindly lent by Messrs. Sutton & Sons, of Reading.

Mr. W. W. Sheath, of Ventnor, staged many very fine seedling Hippeastrum blooms.

THE ROYAL HORTICULTURAL OF IRELAND.

May 9.—A meeting of the Council of the Royal Horticultural Society of Ireland was held at the Offices, 61, Dawson Street, Dublin, on the above date. Sir Percy Grace, Bart., occupied the chair, and the following members of the Council were present:—F. W. Burbidge, Esq., M.A.; Major Domvill, J.P.; Rev. F. C. Hayes, M.A.; D. Ramsay, Esq., H. Crawford, Esq., H. Smallman, Esq., and Greenwood Pim, Esq.

The minutes were then read by Mr. W. G. Hillyard (Secre-

Arrangements were made relative to the summer Rose show, to be held in Merrion Square on Thursday, June 29.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

May 11.—The members of the Committee present at this meeting were W. Thompson, Chairman; G. S. Ball, Vice-chairman; W. Stevens, W. Holmes, R. Johnson, Wm. Bolton, P. Weathers, Thos. Mills (Hon. Sec.). Mr. De Barri Crawshay was present, and was invited by the Orchid Committee to assist in their deliberations. The subjects brought before the Committee were not numerous, but included some very good things.

Mr. G. Shorland Ball (gr., Mr. Gibbons), Ashfield, Wilmslow, sent a magnificent example of Angræcum Sanderianum, with two gorgeous spikes of bloom, with about forty flowers on each spike. This plant was awarded a First-class Certificate, also a Cultural Certificate. A finely flowered piece of Dendrobium Devonianum came from the same collection, and was awarded a Cultural Certificate. Cattleya intermedia alba was well shown from the same collection, and the First-class Certificate awarded some time ago to another plant of this variety was confirmed. A form of Cattleya Schroderæ var Dellense also came from Mr. Ball's collection, but it was very poor thing, distinct as far as the lip was concerned, lacking any character whatever elsewhere, the formation and colouring of the lip giving one the impression that it was a natural hybrid between C. Schroderæ and C. Trianæi, or perhaps C. Gaskelliana; it is sweetly scented, as is C. Schroderæ. Another interesting plant was Cymbidium tigrinum with four well-developed spikes of flower, and bearing evidence of good cultivation, and the Committee recognised this by its dual award of a Cultural Certificate and Award of Merit.

Mr. G. W. Law-Schofield (gr., Mr. Shill), New-Hall-Hey, Rawtenstall, staged a fine plant of Cattleya Skinneri var. oculata, which obtained an Award of Merit; the same gentleman showed a fine plant of Cypripedium Lawrenceanum Hyeanum, "Cookson's var.," raised from seed.

Mr. T. Statter (gr., Mr. Johnson), Stand Hall, Whitefield, exhibited a plant of Lælia Cattleya × Highburyensis.

Mr. John Leeman (gr., Mr. Edge), West Bank House, Heaton Mersey, is an exhibitor who may always be relied upon to bring something good to the meetings, and on this occasion he brought a magnificent form of Odontoglossum polyxanthum called grandiflorum. It is undoubtedly one of the best forms in cultivation, being in form perfect and with brilliant markings; it was profusely flowered. A First-class Certificate was unanimously awarded this plant. The next best exhibit from this collection was Odontoglossum crispum grandiflorum, which variety received an Award of Merit last year. The cultivation of this plant was about as perfect as possible, and the Committee unanimously awarded a Cultural Certificate.

Mr. Duncan Gilmour (gr., Mr. Day), Sandgate, Sheffield, exhibited a few good forms of Cattleya Mossiæ, one of which called "imbricata" received an Award of Merit. Mr. A. J. Keeling, Bingley, Yorks, showed Odontoglossum Rossii majus var. purpureum, and Cattleya Schroderæ splendens.

Mr. John Robson, Altrincham, staged a good variety of Cypripedium Rothschildianum giganteum, and was given an Award of Merit. Mr. Robson also showed Epidendrum bicornutum and Cattleya Skinneri alba, the latter was slightly tinged with colour. *P. W.*

SHIRLEY GARDENERS' & AMATEURS' MUTUAL IMPROVEMENT.

May 16.—The monthly meeting of the above Society was held at the Parish Room, Shirley, Southampton, on the above date, when there was a good attendance of the members, presided over by Mr. B. Ladhams, F.R.H.S.

The lecture, on the "Sexuality in Plants," was given by Mr. A. Angell, Ph D., F.S.I., Public Analyst for the county of Hants, and was illustrated with a series of limelight slides, many of them kindly lent by Messrs. Sutton & Sons, Reading. A cordial Vote of Thanks was heartily accorded Mr. Angell.

Among the exhibits may be mentioned New Holland plants, shown by Messrs. W. H. Rogers & Son, Red Lodge Nursery; also a group of various plants by Mr. B. Ladhams, who showed five new Spiræas. There were shown a good plant of Medinilla magnifica, one of Acalypha Sanderi, Pansies, Ferns, Richardia (yellow), Cactus and Auriculasby various members of the Association.

A resolution to have an outing to Messrs. H. Cannell & Sons, Swanley, July 15, concluded the business.

CIDER AT THE SOMERSET COUNTY SHOW.

This year the cider classes showed very great improvement all round. Though the classes are restricted to the county of Somerset only, they filled exceedingly well, there being seventeen entries in the class for casks of not fewer than eighteen gallons and not more than thirty gallons, made in the autumn of 1898. The Gold Medal was carried off by Mr. W. T. S. Tilley, Shepton Mallett, who swept the board at the Bath and West Show last year. His cider meets the tongue bright and clear; it was rather inclined to be sweet, but it was full, rich, and had plenty of life—an ideal table cider. The Silver Medal went to Mr. R. W. Scott, South Petherton. This was for another full, rich, heavy, fruity cider. The third prize of a Bronze Medal went to Messrs. Waterman & Son, Baltonsborough, for a pleasant cider, which was not nearly so good as another cask from the same maker, which was not mentioned at all, yet the cider in this cask and that in the first prize-winning bottles was identical, and drawn from the same butt. There were sixteen entries in the bottled class. Here the Gold Medal went to a superb exhibit from Messrs. Waterman & Son. His samples were full of natural life and sparkle, with a delicate aroma. Mr. W. T. S. Tilley took Silver Medal for a full, rich, fruity cider. Mr. D. J. Crofts, of Sutton Montis, secured the Bronze Medal with a slightly thinner cider than the preceding ones. Like the cask cider class there was a most decided advance in the general quality of the cider, which must be justly considered the finest and best exhibition of this beverage that the Somerset County Show has yet held. It was noticeable that most of the exhibits were bright and sparkling, scarcely a cloudy lot being present. Evidently the work carried out by Mr. Neville Grenville and the Bath and West of England Society at Butleigh Court has had very beneficial results on the cider-making industry of Somersetshire. *E. G. F. W.*, *Agricultural Gazette*, *May* 15, 1899.

NATIONAL ROSE.

THE following is an extract from the report of this Society for 1898 :—

The past year may be regarded as one of steady progress, whether the point of view taken be that of the Society's exhibitions, the increase in the number of members, or the issue of its publications.

The most complete arrangements had been made by the Society's local representatives—Mr. R. B. Cater, the President of the Bath Floral Fête committee, and Mr. W. F. Cooling, for the southern exhibition, at Bath—but the season unfortunately proved such a very backward one that only exhibitors from the most forward districts were able satisfactorily to compete. In fact, it was without exception the smallest show the Society has yet held. For the same reason the Metropolitan exhibition, which took place at the Crystal Palace a week later, was of rather less than average extent. If, however, not so large as many of i s predecessors, it was certainly one of the best arranged and most enjoyable of recent years. This was principally due to the whole length of the nave having been placed once more at the disposal of the Society, and to the new plan of dividing the exhibits in the amateur and trade classes into distinct sections. The best Rose show of the year was undoubtedly that at Halifax, where 4100 blooms of "Exhibition" Roses alone were staged—making this the most extensive show, with the exception of that at Birmingham in 1890, that has ever been held by the Society in the provinces. At all three exhibitions the attendance of visitors was unusually large.

The conferences held in connection with the Bath and Halifax shows were most successful. Two excellent papers were read, one by Mr. W. F. Cooling, and the other by Mr. George Paul, followed in each case by an animated and interesting discussion. To the authors of those papers the thanks of the committee are due, as well as to Mr. R. B. Cater and the Venerable Archdeacon Brooke for presiding at the conferences.

The sale of the Society's publications during the year has been again very satisfactory, and especially that of the *Hints on Planting Roses*. The first edition of these "Hints" having become exhausted, a new and revised edition was printed, and has recently been distributed to the members with the report of the two Rose conferences.

The committee congratulate the members upon the present satisfactory financial position of the Society. The amount in hand at the beginning of the year was £30 18s. 7*d.*, and now at its close there remains £86 16s. 10*d.* to carry forward to the next account, the total expenditure having been £719 17*s.* 2*d.*, while the aggregate receipts, including last year's balance, amounted to £806 14*s.* Although more than the usual number of changes have taken place in the *personnel* of the non-exhibiting members, the amount received in subscriptions has on only three previous occasions been exceeded.

No application having been received from any northern town for the Society to visit it in 1899, there will be only two exhibitions this year—a Metropolitan and a Provincial show. This the committee cannot but regard as rather a fortunate circumstance than otherwise, for had three shows been as usual held, it would have been impossible to bring out the new edition of the *Official Catalogue of Exhibition and Garden Roses*, which it is proposed should be issued this year, without resorting to the undesirable practice of calling upon the members to contribute to a special fund to defray the cost of its publication. The Metropolitan exhibition will be held, as usual, at the Crystal Palace on the first Saturday in July; while the Provincial show will take place at Colchester, in conjunction with the Colchester Rose and Horticultural Society, on the following Thursday, July 6. In order that the early-flowering Roses be not altogether overlooked, it has been decided to offer a few prizes at the Royal Horticultural Society's Rose show, which will be held at the Drill Hall, in James Street, Westminster, on June 27, at which members of the National Rose Society may compete.

ROYAL BOTANIC.

MAY 17.—The exhibitions of the Royal Botanic Society become worse and worse. The annual summer display on Wednesday last was certainly poorer than any of its predecessors that has come under our notice. There was little competition in the general classes, and beyond a few exhibits from the trade, the rest of the display was not good in quality. The situation and advantages possessed by this Society are such, that it is lamentable that its exhibitions have become so poorly patronised. The National Tulip Society's Show was held in conjunction with the above, and a report will be found below.

Messrs. T. RIVERS & SON, Sawbridgeworth, Herts, exhibited nine pot-trees in fruit of their new Nectarine, named Cardinal, and two dozen or so fine fruits.

Caladiums were shown in a group of much merit by Messrs. JOHN PEED & SONS, who had large specimens of a considerable number of choice varieties. Madame J. Box, Triumph de Comte, John Peed, and Mrs. Harry Veitch were some of the best.

Messrs. R. & S. CUTHBERT's exhibit of hardy Azaleas made a very pretty effect grouped upon one of the grass mounds. The varieties appeared to be similar to those staged on Tuesday at the Drill Hall.

Messrs. KELWAY's beautiful Tree-Pæonies, that were massed in an attractive exhibit at the Drill Hall, appeared to much less advantage here.

Mr. CHAS. TURNER, of the Royal Nurseries, Slough, was the exhibitor of a group of plants of Souvenir de la Malmaison Carnation var. Princess May, similar to those noticed upon the previous day at the Drill Hall.

Mr. W. RUMSEY, Joyning's Nursery, Waltham Cross, showed a collection of upwards of twenty-two dozen cut Roses. A large number of the most popular varieties was represented, but especially Niphetos and Mrs. W. Rumsey.

Messrs. W. PAUL & SONS, Waltham Cross, Herts, had a fine exhibit of Rose-trees in pots, and of cut blooms.

Messrs. JOHN LAING & SONS, Forest Hill Nurseries, S.E., contributed a very meritorious collection of stove and greenhouse plants.

PURNELL PURNELL, Esq., Woodlands, Streatham Hill, S.W., made an exhibit of alpine plants, chiefly composed of Primulas, Auriculas, Sempervivums, and Saxifragas.

Some pretty table decorations were shown by Mr. L. H. CALCUTT, Mr. J. PREWETT, RAYLEIGH, and others.

COMPETITIVE EXHIBITS.

Mrs. ABBOT, South Villa, Regent's Park (gr., Mr. Geo. Kelf), had 1st prize for a pair of specimen Cordylines, showing Lindeni, and Lord Wolseley; and 1st prize also for six specimen Palms, including a very fine plant of Livistona chinensis.

The 1st prize for a collection of stove and greenhouse plants was won by Mr. Thos. Abbott, gr. to CAMPBELL NEWINGTON, Esq., The Holme, Regent's Park. The exhibit was composed of moderate specimens of ordinary foliage and flowering species.

Messrs. A. W. YOUNG & Co., Stevenage, Herts, was awarded a 1st prize for a collection of hardy herbaceous plants, but the exhibit, in our opinion, was not worthy of the award, albeit there was an abundance of cork-bark, and Isolepis gracilis was grouped with hardy Saxifragas and Polyanthus. The same exhibitors won 2nd prizes for zonal Pelargonium plants, and cut blooms of species of stove and greenhouse plants.

The 1st prize for six plants suitable for table decoration was won by W. C. WALKER, Esq., Percy Lodge, Winchmore Hill (gr., Mr. G. Cragg). He had pretty little specimens of Eulalia gracilis, Reedia glaucescens, Aralia gracillima, two Codiæums, and Geonoma gracilis.

Mr. G. CRAGG won 1st prize for a group of Orchids. There were numerous specimens of Cattleya citrina in flower suspended (rather inappropriately) from a towel-horse. The Odontoglossums, Dendrobiums, Cattleyas, &c., included several meritorious specimens. The 1st prize for six Orchids was taken by LUDWIG MOND, Esq., 20, Avenue Road, N.W. (gr., Mr. J. O. Clarke). A specimen of Odontoglossum citrosmum was a very good one.

THE ROYAL NATIONAL TULIP.

MAY 17.—The exhibition of this Society, held in the Gardens of the Royal Botanic Society on the above date, showed there is still some vitality attaching to it, and the show in itself, considering the late season, was an encouraging one. The flowers were generally small, and there were not lacking evidences that they had been hastened into bloom. The exhibitors were few, but everyone had done his best to contribute to the display.

A Silver Cup, given by Messrs. BARR & SONS, King Street, W.C., for eighteen dissimilar varieties of Tulips, two feathered, two flamed, and two breeders of each class, brought but one collection, the cup being awarded to Mr. J. W. BENTLEY, Kersal, Manchester, who staged medium-sized blooms of bizarres, feathered, General Grant and Masterpiece; flamed, San José and Excelsior; byblœmens, feathered, Adonis and Ashmoles 126; flamed, Othello and Chancellor; roses, feathered Mabel and Julia Farense; flamed, Clio and Annie McGregor. Of breeders there were of bizarres, Goldfinder, and Excellent; byblœmens, W. Parkinson and Adonis, the last superbly coloured; roses, Rosehill and Annie McGregor, both very handsome.

There were four exhibitors of twelve dissimilar rectified Tulips, two feathered and two flamed of each class. Mr. A. D. HALL, Wye, Ashford, Kent, was 1st with bizarres-feathered Sir J. Paxton and Lady F. Cavendish, flamed Samuel Barlow and Sir J. Paxton, byblœmen-feathered Proserpine and Trip to Stockport; flamed George Edward and Adonis; roses, feathered Count and Sarah Headley; flamed, Annie McGregor and Aglaia.

There were four stands of six dissimilar rectified Tulips, one feathered and one flamed of each class. Mr. J. W. BENTLEY was 1st with bizarre-flamed San José, and feathered Masterpiece; byblœmens, Trip to Stockport, flamed; and the same variety feathered; roses, flamed, Mabel; and feathered, Julia Farnese.

There were but two exhibitors of three-feathered Tulips, showing the difficulty of getting them into bloom. Mr. J. W. BENTLEY was 1st, with bizarre Masterpiece, byblœmen Guido, and rose Modesty.

There were five exhibitors of three-flamed Tulips, Mr. A. D. HALL taking the 1st prize with bizarre Dr. Hardy, byblœmen Talisman, rose Aglaia.

The breeder Tulips were very handsome, and attracted much attention from visitors. Mr. A. D. HALL had the best six, two of each class, viz., bizarre W. Lea, very dark, and Goldfinder; byblœmens, Adonis and Talisman; roses, Annie McGregor, both feathered and flamed; Mr. C. W. NEEDHAM was 2nd.

Mr. A. HALL had the three best breeders: bizarre, John Heap; byblœmen, Maid of Orleans; rose, Annie McGregor.

The 1st of the Samuel Barlow prizes for a pair of rectified Tulips, one feathered and one flamed, was won by Mr. C. W. NEEDHAM, who had flamed bizarres, Samuel Barlow, and feathered rose Modesty; 2nd, Mr. J. W. BENTLEY, with bizarres, flamed Lord Stanley; feathered rose, Julia Farnese.

The best feathered Tulip selected from the whole show was bizarre Richard Headley, shown by Mr. A. CHATER. The best flamed was byblœmen Geo. Edward, from Mr. A. D. HALL, a new seedling of excellent character, raised by Schofield, of Wortley, Leeds. The premier breeder was byblœmen Adonis, very fine in colour, shown by Mr. A. D. HALL.

Mr. A. D. HALL won the Silver Medal offered for a collection of English Florists' Tulips, having about fifty blooms of unnamed varieties, in addition to bunches. A Gold Medal was awarded to Messrs. BARR & SON, for a collection, having of bizarres, Masterpiece, Sir J. Paxton, and Lord Stanley; byblœmens, Lord Denman, Duchess of Sutherland, and Bessie; roses, Mabel and Aglaia.

[The term "accumulated temperature indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following :—

0, Scotland, N. *Principal Wheat-producing Districts*—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. *Principal Grazing, &c., Districts*—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

THE following summary record of the weather throughout the British Islands for the week ending May 13, is furnished from the Meteorological Office :—

"The *weather* was fine and dry in all parts of the kingdom during the earlier days of the period, but after Tuesday the conditions became gradually unsettled, and during the remainder of the week showers or steady rain, occasionally accompanied by thunder and lightning, were experienced in nearly all districts. Some of our southern and south-eastern stations, however, had little or no rain.

"The *temperature* did not differ materially from the mean value for the time of year. The highest of the maxima, which were registered on the 8th in Ireland and Scotland, and on the 11th over England, ranged from 70° in 'Ireland, N.,' and 'England, S.,' and 69° in 'England, S.W.,' to 62° in 'England, N.W.,' and to 66° in 'England, N.E.' During Friday and Saturday most of the maxima recorded in the north and north-west were but little above 50°, and in some instances they were below that value. The lowest of the minima occurred, as a rule, either on the 7th or 8th, and varied from 27° in 'Scotland, E.,' 29° in 'Scotland, N. and W.,' and 31° in 'England, N.E.,' and over Ireland, to 38° in 'England, E.,' and to 45° in the 'Channel Islands.'

"The *rainfall* was more than the mean in most districts, but considerably less in 'Scotland, N.,' 'England, S. and E.,' and the Channel Islands. In 'Scotland, E.,' the fall was twice, and in 'England, N.E.,' three times as much as the mean value.

"The *bright sunshine* was less than the mean in most districts, but exceeded it in 'Scotland, N.,' 'England, S.,' and the 'Channel Islands,' and just equalled it in 'Ireland, N.' The percentage of the possible duration ranged from 55 in 'England, S.,' and 53 in the 'Channel Islands,' to 30 in 'Scotland, E.,' and 23 in 'England, N.E..'"

MARKETS.

COVENT GARDEN, MAY 18.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Potatos.

Bruce, Saxon, and Main Crop, 80*s.* to 100*s.*; Up-to-Date, 95*s.* to 105*s.*; Dunbar Main Crop, 100*s.* to 110*s.* *John Bath, 32 and 34, Wellington Street, Covent Garden.*

Remarks.—Spring Spinach has commenced. Gooseberries are coming in larger quantities. Cabbage coming better. Asparagus plentiful. Home-grown Tomatos are now coming freely, and of good quality.

SEEDS.

London: *May* 17.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report to-day's market thinly attended, with but little business doing. Sowing orders for Clover and other farm seeds are now naturally getting fewer and smaller. There is still some inquiry for Tares; whilst the sale for Mustard and Rapeseed improves. Hemp-seed continues both scarce and dear; and Canary-seed is attracting increased speculative attention. There is also a better sale for Blue Peas and Haricot Beans. Scarlet Runners are in good request, at the low prices now current. For Linseed the trade is steady. The Board of Trade Returns give the imports of Clover and Grass-seeds into the United Kingdom for the four months of this year, ending April 30, 1899, as 144,583 cwt, value £270,850, as against 203,798 cwt., value £395,664, for the corresponding period of 1898.

CORN.

Average Prices of British Corn (per imperial qr.), for the week ending May 13, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.		1899.		Difference.	
	s.	d.	s.	d.	s.	d.
Wheat	45	11	25	4	− 20	7
Barley	27	1	23	11	− 3	2
Oats	21	1	17	9	− 3	4

FRUIT AND VEGETABLES.

Glasgow: *May* 17.—The following are the averages of the prices recorded since our last report:—Apples, Canadian Spies, 14*s.* to 18*s.* per barrel; Western States' Russets, 18*s.* to 20*s.* do.; Oranges, 6*d.* to 1*s.* per dozen; Grapes, home, 2*s.* to 4*s.* per lb.; do. foreign, 6*d.* do.; Tomatos, Guernsey, 4*d.* to 8*d.* per lb.; do., Scotch, 5*d.* to 8*d.* do.; Spring Cabbages, 6*d.* to 1*s.* per dozen; Cauliflowers, Edinburgh, 2*s.* to 2*s.* 6*d.* per dozen; Leeks, 1*s.* 6*d.* to 4*s.* per dozen bunches; Mint, green, 6*d.* per pound bunch; Onions, 4*s.* 6*d.* to 5*s.* per cwt.; Parsley, 1*s.* 6*d.* to 2*s.* per stone; Carrots, new, round, 1*s.* per bunch; do., 4*s.* 6*d.* to 7*s.* per cwt.; Cucumbers, 4*d.* to 5*d.* each; Lettuces, round, 1*s.* 3*d.* to 1*s.* 6*d.* per dozen; do., Cos, 4*s.* to 5*s.* do.; Radishes, long, English, 1*s.* 6*d.* per dozen bunches; Horseradish, 1*s.* 6*d.* to 2*s.* per bundle; round Radishes, 1*s.* to 1*s.* 6*d.* per dozen bunches; Mushrooms, 1*s.* to 1*s.* 2*d.* per lb.; Beetroots, 6*d.* to 7*d.* per dozen; Mustard and Cress, 3*d.* per punnet; Spinach, 2*s.* to 4*s.* per stone; Swedes, 2*s.* to 2*s.* 6*d.* per bag; Broccoli, Irish, 2*s.* to 2*s.* 6*d.* per dozen; Seakale, 1*s.* 6*d.* per bunch; French white Turnips, 1*s.* to 1*s.* 3*d.* per bunch.

Liverpool: *May* 17. — *Wholesale Vegetable Market.* — Potatos, per cwt., Main Crop, 3*s.* 6*d.* to 4*s.* 3*d.*; Bruce, 2*s.* 10*d.* to 3*s.* 6*d.*; Champions, 2*s.* 9*d.* to 3*s.* 3*d.*; Turnips, swedes, 2*s.* 6*d.* to 3*s.* do.; Carrots, 4*s.* to 5*s.* do.; Parsley, 6*d.* to 8*d.* per dozen bunches; Onions, foreign, 4*s.* to 5*s.* per cwt.; Cucumbers, 2*d.* to 3*d.* each; Cauliflowers, 1*s.* 3*d.* to 2*s.* per doz.; Cabbages, 6*d.* to 1*s.* do. *St. John's.*—Potatos, 1*s.* to 1*s.* 2*d.* per peck; do., new, 2*d.* to 4*d.* per lb.: Grapes, home, 2*s.* to 4*s.* per do.; Pines, English, 4*s.* to 6*s.* each; Strawberries, 4*s.* to 5*s.* per lb.; Peas, 6*d.* to 1*s.* do.; Cherries, 6*d.* to 10*d.* do.; Cob Nuts, 6*d.* to 8*d.* do.; Apricots, 1*s.* per dozen; Asparagus, 1*s.* 6*d.* to 3*s.* per bundle; Cucumbers, 3*d.* to 4*d.* each; Mushrooms, 1*s.* 2*d.* per pound and basket. *Birkenhead.*—Potatos, 1*s.* to 1*s.* 2*d.* per peck; do., new, 2*d.* to 6*d.* per pound; Peas, 6*d.* do.; Asparagus, 3*s.* to 4*s.* per 100; Cucumbers, 2*d.* to 6*d.* each; Strawberries, 4*s.* per pound; Cherries, 8*d.* to 10*d.* do.; Apricots, 1*s.* per dozen; Gooseberries, 8*d.* per pound; Grapes, home, 1*s.* 6*d.* to 3*s.* do. Mushrooms, 1*s.* to 1*s.* 6*d.* do.

GARDENING APPOINTMENTS.

Mr. W. Dandridge, late Gardener at Arrandene, Mill Hill, as Gardener to E. Ford, Esq., Bridgen Place, Bexley, Kent.

Mr. John Stubley, late Foreman at Fenay Hall Gardens, Huddersfield, as Gardener to Henry Appleton, Esq., St. Anns' Grange, Leeds.

Mr. W. G. Littlejohn, Gardener to Col. G. J. Scurfield, Hurworth House, Hurworth-on-Tees.

Mr. Wm. Dinsdale, Gardener to John S. Barwick, Esq., Thimbleby Hall, Northallerton.

Mr. Herbert Pearson, Gardener to the Rev. G. R. Dupuis, Sessay Hall, Thirsk.

Mr. H. Tate, Gardener to Rev. C. T. Kales, Newton-le-Willows, R.S.O., Yorks.

Mr. R. E. Brain, late Gardener at Danvers House, Culworth, as Gardener to Mrs. J. Savory, Sunrising, Banbury.

Mr. Charles Richardson, late Gardener to Sir Joseph Verdin, Bart., Brockhurst, Northwich, Cheshire, as Gardener at Bryn-y-neaudd Castle Gardens, Llanfairfechan, N. Wales.

Mr. George Shergold, for the past two years Head Gardener to C. E. Shea, Esq., The Elms, Foot's Cray, as Head Gardener to J. F. Gems, Esq., Eaton Grange, Cobham, Surrey.

Mr. J. A. Latter, for the last two and a half years Head Gardener at Elstead Lodge, Godalming, Surrey, as Head Gardener to John Godden, Esq., Ferncliff, Tunbridge Wells.

CATALOGUES RECEIVED.

Wood & Ingram, Huntingdon and St. Neots—Bedding and other plants.

E. M. Richford, 34, Cheapside, London, E.C.—India-rubber Stamps, Tyre Pads, &c.

J. B. Baillière & Sons, 19, Rue Hautefeuille, Boulevarde Sainte Germain, Paris—Books.

Adaptation to Circumstances.— Much attention is now paid to the co-relation between structure and conditions of life. The plants growing in desert places have a peculiar conformation, aquatic plants also, and so forth. Nevertheless, we sometimes meet with curious exceptions, one of which was given us lately by Mr. Scrase Dickens. The Heaths, as everyone knows, generally grow in dry places, and the leaves are sharply rolled round at the margins as to nearly cover the lower surface, where the stomata are placed, and thus impede undue evaporation. Mr. Scrase Dickens' specimen, however, showed that this conformation is not confined to plants growing in dry places, for the specimen of Erica mediterranea, with which he obliged us, was found growing in wet, swampy places, in Connemara.

Osier Cultivation.—Osier culture is being greatly developed in Germany, and there can be no doubt that a large area of the land unsuitable for ordinary agricultural crops in this country might be profitably utilised in the cultivation of Willows suitable for basket-making. More especially has the culture of Osiers been developed in the valleys of the Wurn and the Roev, near the borders of Holland. The prosperity of the district is reported to have been greatly increased by the introduction of this new industry. Basket-making in Germany is a considerable industry, employing nearly 40,000 persons annually, representing nearly £625,000 capital, and using the growth of over 48,000 acres of Willows, valued at £396,000 on the stocks, or nearly double that amount when peeled. A considerable proportion of the baskets used for marketing fruit and vegetables in this country come from Germany; and as they could be equally as well made at home, we are pleased to learn that the question is receiving the attention of several of the Technical Education Committees.

Sale of Orchids at Manchester.—A sale of surplus Orchids in the collection of F. Hardy, Esq., Tyntesfield, was conducted on the 16th and 17th inst., by Messrs. Protheroe & Morris. Many of the principal buyers from London were present, including Messrs. Jas. Veitch & Sons, Hugh Low & Co., F. Sander & Co., Mr. Tracey, and Mr. A. Outram. The majority of the rare and most valuable specimens were purchased by southern buyers. On the first day the sale realised about £1100, and on the second day, £800. A plant of Cypripedium × Fred Hardy realised 50 guineas, and two specimens of C. × Jas. H. Veitch were sold respectively for 80 guineas (with two growths), and 52 guineas (one growth); C. insigne Sanderæ was sold for 31 guineas. Other leading prices were:—Lælia purpurata Hardyana, 18 guineas; L. anceps Amesiæ, 14 guineas; Lælio-Cattleya Macfarlanei, 22 guineas; L.-C. Pallas superba, 40 guineas; C. Mendeli, 45 guineas; C. Mossiæ Wagneri, 21 guineas; L.-C. × Bella, 46 guineas; C. Mendeli, Quorn House var., 42 guineas.

Answers to Correspondents

Bordeaux Mixture: *C. N. M.* The materials consist of copper sulphate, 4 lb.; fresh lime (unslaked), 4 lb.; water, 40 gallons. Care should be taken that the lime is of good quality, and that it has not become air-slaked. Dissolve the copper sulphate in a tub, and slake the lime in a box. When the sulphate is dissolved, put in slowly the slaked lime-wash, after it has by settling become somewhat clear, and stir the whole well together. To ascertain if the quantity of lime is sufficient, dip a clean knife-blade into the mixture; if copper be deposited on it there is too much copper, and more lime must be added until no deposit is made. Failure to do this may result in injury being done to tender foliage. A small excess of lime will do no harm.

Chrysanthemum Leaf-spot: *S. W.* A disease due to a fungus, Septoria chrysanthemi. The brown dry spots are quite distinct from rust. The usual remedies, Bordeaux Mixture and potassium sulphide, sprayed over the plants have given fairly satisfactory results. The solutions used should be rather dilute to prevent spotting of the foliage. Recently Mr. R. W. Hodder recommended a whale-oil soap mixture for the rust (see *Gardeners' Chronicle*, January 28, 1899, p. 63); we believe it would be equally effective against this leaf-spot fungus. Select cuttings from plants free from this disease, as it is generally most severe amongst the cuttings. *W. G. S., Leeds.*

Disease of Gooseberries: *Stanley Platt.* The foliage, &c., sent is infested with Æcidium grossulariæ — "Gooseberry-rust" (fig. 119), see also *Gardeners' Chronicle*, August 20, 1898, p. 145. There is no known cure for an attack. Preventive dressing with the Bordeaux Mixture might ward off an attack. All affected leaves and fruits should be collected and burned.

Fungus on Juniper Twigs: *C. C. Ellison.* Gymnosporangium tremelloides, the mycelium of which penetrates the bark, causing thickening of the twigs and a premature death of the distal portion above the swellings. The brown, velvety spore-cushions break out between the bark-scales on the swollen portions about the middle of April. In May or June, the cushions swell up and become brownish-yellow, gelatinous clumps, dotted over with dark points. This species of fungus is of great importance, on account of its attacks on Apple-trees, producing in the spore-form Roestelia on the leaves. Every means should be taken to destroy it by cutting-off and burning infested twigs, and the use of the Bordeaux Mixture on trees infested with it.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*H. O. E.* 1, Sedum acre aureum; 2, Sedum sarmentosum; 3, Saxifraga muscoides; 4, 5, forms of Phlox subulata; 6, send when in flower.—*J. R., France.* The flowers arrived dry, and with the colour gone, and pollinia imperfect. 1, is doubtless Spathoglottis Petri; 2, conforms to all the characters of an albino of Broughtonia lilacina (Læliopsis Dominyensis); we have heard of white forms of it, and also Broughtonia sanguinea, but have never seen them.—*A. L.* 1, Dendrobium clavatum; 2, Phalænopsis Luddemanniana—a good variety; 3, Odontoglossum cordatum.—*K. H.* Pyrus Malus floribunda.—*H. H. E.* A Streptocarpus, in which we see nothing unusual.—*Mrs. Williamson, Canterbury.* Melianthus major.—*H. W.* 1, Saxifraga Mawiana; 2, Doronicum caucasicum; 3, Iberis Tenoreana; 4, Corydalis nobilis; 5, Epimedium alpinum; 6, Alyssum saxatile.—*Dinwoodie.* Medinilla magnifica.—*G. H. M.* Magnolia Soulangeana. Your Grapes are rusted from syringing in the sunlight, or perhaps from excess of sulphur on the pipes.—*J. W.* 1, not found; 2, Tulip; 3, a Savin with a fungus—Gymnosporangium (see above); 4, Scilla with a fungus—Puccinia: further information next week.—*W. M. & Co.* Æcidium grossulariæ, a fungus (see fig. 120). —*Card-box: no name.* 1, Ceanothus azureus; 2, Choisya ternata; 3, Bridgesia spicata; 4, Cistus ladaniferus; 5, Pyrus Maulei; 6, Vinca major; 7, Euonymus japonicus variegatus; 8, Kerria japonica; 9, Viburnum Tinus.—*Wills.* Melia Azedarach.—*J. P.* 1, Pittosporum Tobira; 2, Styrax officinale; 3, Exochorda grandiflora.—*M. R.* 1, Fabiana imbricata; 2, Forsythia viridissima: perhaps, specimen insufficient.—*G. H. S.* 1, Uvularia perfoliata; 2, Piptanthus nepalensis; 3, Toxicophlœa spectabile; 4, Amelanchier vulgaris; 5, Choisya ternata; 6, Viburnum Opulus. —*W. O.* Arum crinitum.—*G. H.* 1, A Cedar which we cannot name without seeing the tree; 2, Abies cephalonica; 3, Cupressus thyoides; 4, Taxodium sempervirens; 5, Juniperus communis; 6, Cephalotaxus pedunculata var. fastigiata.—*B. B. M.* The spotted leaf is Begonia incarnata maculosa; the other referred to by you was not found.—*S. G. S.* Both remarkably good varieties of Dendrobium chrysotoxum.—*T. R.* Cattleya intermedia.—*P. C. P.* Probably the seeds of an Alstrœmeria.—*G. H.* 3, Cuphea ignea.—*J. Milsom.* 1, Pittosporum tenuifolium; 2, Viola hirta.—*F. C.* Scilla campanulata.—*H. A. M.* Ribes aureum.

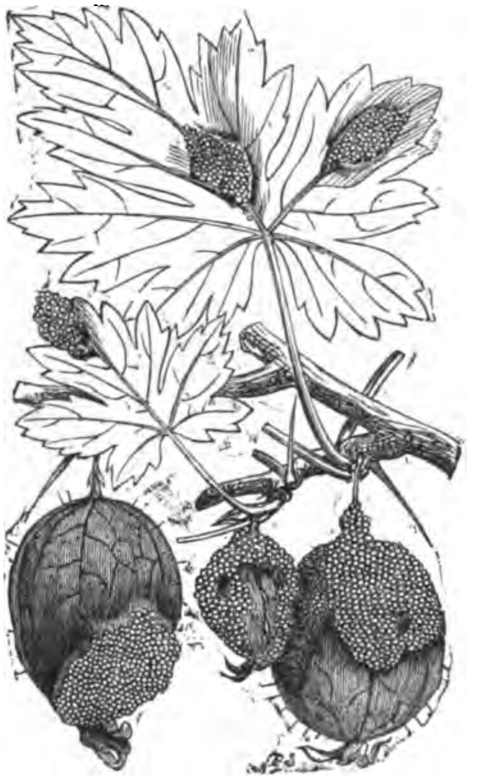

Fig. 119.—Æcidium grossulariæ: rust of gooseberries.

Paris Lily: *W. C. Leach.* Paris quadrifolia, probably.

Patron Saint of Gardeners: *Godfrey.* The reputed patron saint of gardeners is according to Mrs. Bury Palliser, who wrote an account of *Brittany and its Byeways*, London, John Murray, 1870 (St. Fiacre); see *Gardeners' Chronicle*, January 1, 1870, p. 13.

Peaches in Close Clusters: *Anxious Reader.* The clusters of fruit have originated from an union of the ovaries of the blossoms, for which the extra vigour of the trees may account.

Pear Diseased: *Notts.* The young shoots and leaves are attacked by the Pear-leaf Blight, caused by fungus (Entomosporium maculatum). It is one of the worst of orchard diseases, because not only does it cause loss of the foliage, but it passes on to the young fruit and makes it stunted and unshapely. The disease is recognised by the dark-red spots standing up from the surface of the leaf or fruit. It appears first on the young unfolding shoots, and is said to occur more frequently on seedling Pears than on grafted plants. The remedy which has been found most successful is Bordeaux Mixture. This is sprayed over the trees from the time the leaves unfold, and at intervals of two to three weeks till August. It should then be discontinued, as the Mixture may spot the ripening fruit. The spraying machine ought to be one of the larger forms, and strong enough to reach the topmost twigs. In autumn all fallen leaves should be collected and burnt, and in pruning care should be taken to remove all twigs which were attacked the previous season. *W. G. S., Leeds.*

Rhododendron Leaves: *H. M.* A mechanical injury, caused probably by the dogs, as you suggest. There is no fungus. Put up a net round the bushes, or take other means to keep the animals at a distance.

Soil Analysis: *H. A. C.* If you are a Fellow of the Royal Horticultural Society apply to the Secretary.

Sweet Peas and Manure: *G. E. P.* The substances named are very suitable manures for the plants. Superphosphate of lime would supply the one, and the potash might be afforded by wood-ashes if you have them, or by commercial potash. Carbonate of potash may be safely and usefully employed at the rate of 500 lb. per acre. Soluble calcium, phosphate, or superphosphate of lime, 300 lb. to 500 lb. per acre. These quantities would suffice for one dressing. If nitrate of soda be employed at the rate of 80 lb. per acre, the superphosphate might be reduced by one-half.

Vitis Coignetiæ: *R. C. D.* If your plant is growing in a pot, and has as yet not made much growth, it may be planted forthwith. Let the station for the plant be well prepared, and make the drainage good, and be sure that the position, whether on wall or trellis, is fully exposed to the sun. It is a rampant grower, needing a good deal of space.

Wireworm: *Sufferer.* You can do little whilst the ground is under crop beyond applying agricultural salt and nitrate of soda in safe doses twice or thrice for the destruction of the wireworms; but as a palliative you may sow Lettuce-seeds among the crops, the "worm" having a partiality for the roots of these plants. In the autumn or early winter it would be well to dress the land heavily with gas-lime and salt, letting these substances lie on the surface till February or later, then trench the soil as deep as you prudently may, using more gas-lime or quick-lime as the work of trenching proceeds. It is probable that this sort of procedure will have to be extended over several years.

THE
Gardeners' Chronicle

No. 648.—SATURDAY, MAY 27, 1899.

THE FERTILITY OF SOILS.

THE factors upon which the fertility of the soil depend are many. The amount of plant-food and its degree of solubility, the mechanical texture or tilth, and the climate, which includes temperature, amount of rainfall, &c., are the chief of these.

Soils to be fertile must contain the elements of plant-food in such forms that they can be readily used for the nutrition of vegetation. At the same time, its condition must not be too loose, else a firm hold will not be afforded to the roots of plants, and there will be too much drainage and evaporation; nor must it be too heavy and plastic, for then air and water could not freely permeate it, nor the roots extend themselves beyond a very limited area. Generally speaking, light, loose soils are not as rich in plant-food as those in which clay predominates; yet, on account of their excellent condition of tilth, and the ease with which they are worked, they are specially adapted for most horticultural purposes, and having a sufficiency of manure, they often yield in favourable seasons heavier crops than the stronger soils would do. Stiff, heavy clays, though rich in inorganic food, potash, and phosphoric acid, are often poor in nitrogen, while their mechanical condition is such as to prevent thorough aëration and the penetration of the roots. It is these soils especially that are benefited by drainage. By a system of drainage the water which saturates the surface-soil is carried off, air allowed to permeate, the whole is rendered more friable and easily worked, and much plant-food is converted into assimilable forms.

Where sand largely preponderates, the soil is not retentive of moisture and fertilising material, especially if the subsoil be light, and though easily worked it is not so desirable in very dry seasons as on a heavier soil. A proper proportion of sand and clay, therefore, for many reasons, makes the best soil. With the clay and sand, varying amounts of peaty matter, or humus, derived from the decomposition of vegetable matter, may be mixed. In horticulture leaf-mould is largely used. Calcareous matter, chalk, lime, and bone-meal, are usually associated, and a light proportion of these exerts a beneficial influence upon the tilth of the soil, as well as upon the solubility of the plant-food. By the slow decomposition of the clay, the vegetable matter, and the lime, valuable plant-nutrients, are liberated in a soluble form, and therefore the function of these soil constituents is not only mechanical but chemical.

The most important inorganic constituents of a soil are potash and phosphoric acid. These, together with nitrogen, are known as the essential elements of plant-food.

To understand the question of soil-fertility, the gardener should become familiar with these matters, should know what these elements will do for crops and plants, and when and how to apply them.

Nitrogen.—This element, like potash, lime, and phosphoric acid, is an essential constituent of all plants. In its free state it is a permanent gas, and is one of the most widely distributed elements, comprising about four-fifths of the earth's atmosphere. This vast supply of nitrogen is, however, of no direct value to plants, since they are unable to use it, except when combined with the elements oxygen or hydrogen, forming nitric acid and ammonia, that may be taken up through the roots of plants. Leguminous plants, like Peas, Beans, Lupins, &c., and possibly Orchids, are indirectly able to build up their nitrogenous ingredients from the free nitrogen of the air, through the activities of microscopic plants (known as bacteria), intimately associated with them; other plants may, possibly, under favourable conditions to some extent have the same faculty.

Nitrogen is present in the soil in simple combinations as nitrates or ammonia salts, or as more complex organic compounds, forming the dark coloured humus especially abundant in peat, leaf-mould, and forest soils. The total quantity of nitrogen in ordinary good soils varies between 0·1 and 0·2 per cent.; occasionally the nitrogen content will approach one per cent., as in the case of rich pasture soils. Peat soils will often contain over two per cent. of nitrogen; this is, however, largely in a combination that will not directly sustain plant life, but has to undergo a weathering process before the plant can make use of it.

Nitrogenous manures help to strengthen plants in their earlier growth, favour leaf development, and give a deep green healthy colour to the foliage; applied in excessive quantities they induce rank growth at the expense of the development of the fruit.

Phosphoric acid is present in soils in combination with a number of other chemical substances, which exert a very beneficial influence on the growth of plants. Phosphoric acid is found in soils partly in a form that plants can readily dissolve and make use of in the building of their structure, partly in an insoluble form which under the influence of water, carbonic acid and air, or the mineral components of the soil are gradually changed into available plant food. There is only a small quantity of phosphoric acid in ordinary soils, viz., less than 0·2 per cent., and often only 0·05 per cent.; but as the content is not decreased in any way except by the growing of crops, the soil will only become deficient in this constituent in case of continuous cropping without manuring.

Phosphoric acid is of special importance in the early life of plants; it stimulates the assimilation of mineral substances in the plant, and favours the development of its root system. There is an intimate relation between the nitrogenous principles and the phosphoric acid in plants, and we find that, generally speaking, a high nitrogen content is accompanied by a high percentage of phosphoric acid. The phosphoric acid of plants is usually concentrated in their maturing organs, the flower and seed.

Potash is found in Nature in combination with acids like sulphuric, carbonic, and silicic acid. Potash is generally distributed in small quantities in most soils, except light sandy soils, which are apt to be deficient in this fertilising element; it is found in ordinary soils in somewhat larger quantities than phosphoric acid, namely, from one to three-tenths of one per cent., and occasionally as much as one per cent. in case of soils originating from granitic, basaltic, and other rocks rich in potash. Like phosphoric acid, potash may be present in the soil in a non-available form, especially as double silicates, that are but slowly decomposed through the action of water, air, and other constituents of the soil.

Potash is found in the largest quantities in foliage plants, in leguminous plants, in Vines, and in Potatos. It is of the greatest value to plants, in facilitating the flow of sap, and the diffusion of starch from cell to cell. It gives increased strength to the cell structure of plants and has in general a beneficial influence on the flavour and texture of fruits and Potatos.

Lime is present in most fertile soils in sufficient quantities to allow of the production of large crops, but occasionally there will be too little of it to reach this end, in which case the addition of some lime compound to the soil, will produce very beneficial results. It is considered that a lime content of one-half of one per cent. an ample supply in light soils, while heavy soils may need 2 per cent. or more.

The good effects from the addition of lime to soils do not come only from the increase of an ingredient essential to plant growth, but the mechanical condition of the soil, its texture, water and heat-retaining capacity, are improved. This same is true in perhaps all cases when fertilisers are applied to soils, a fact which is generally overlooked by horticulturists.

CAMBRIDGE BOTANIC GARDEN.

In the *Gardeners' Chronicle* for November 4, 1882, was published an illustrated article upon the University Botanic Garden, which contained details of the history of the establishment, and of the purposes it serves in respect to the University. We do not propose for the moment to speak of these matters, but to reproduce a few notes recently taken when having occasion to visit Cambridge, the opportunity was embraced to obtain a very hurried glimpse of the plants under Mr. Lynch's care.

Temperate-house.—This structure contains some capital specimens of the cooler-growing Palms, and a collection of miscellaneous species of plants that need but slight protection from the weather. In bloom was noticed Grevillea glabrata, an Australian species introduced in 1838. It is an erect-growing glabrous shrub, and the plant at Cambridge, which is many feet in height, is against the glass side of this house. An extremely beautiful effect was made by an abundance of axillary racemes of white pendulous flowers; the plant cannot be too strongly recommended for cultivation in temperate houses or large conservatories. Also the handsome North American Honeysuckle, Lonicera sempervirens minor; the well-known Choisya ternata; Cistus monspeliensis, a southern European species, with white-petalled flowers and yellow centres; also Macleania insignis, a Vacciniaceous plant, from the American Andes, with orange-red flowers; Heterotoma lobelioides, the bird-plant of Mexico, so named from a supposed resemblance the flower bears to a bird. The plant belongs to the Lobelia family, and has alternate petiolate leaves. The flowers are a shade of red and yellow, the curious corolla being somewhat tubular; it was introduced in 1861.

Water-Lily House, &c.—An excellent photograph of the interior of this house was given in the issue of the *Gardeners' Chronicle* for June 14, 1890. It contains a very representative collection of water and semi-aquatic plants. The tank, which covers the greater part of the floor space, is occupied with species of Nymphæa, including some of Marliac's hybrids, and many of the plants are now in bloom. There are good specimens of the Paper Reed

(Papyrus antiquorum), Thalia dealbata, Sagittarias, Luffa acutangula, &c. We noticed a plant of Brocchinia cordylinoides, a rare Bromeliad introduced to Britain in 1888. In the natural habitat of the plant, the Utricularias are found growing in the axils of the leaves that closely wrap the stem. There is a very fine plant of Norantea guianensis in the Palm-house, but it has not flowered. Bignonia purpurea, figured in these columns from Cambridge last year, furnishes one of the pillars, and although it has not flowered, the specimen of Kendrickia Walkeri, presented by Sir J. Hooker some years ago, is probably the finest in this country. Richardia Rehmanni, which has been described as the pink-flowered Calla, was in bloom, but it is a very disappointing plant here as elsewhere, and the suspicion of pink is an extremely faint one.

The Ferneries.—There are three Fern-houses, containing respectively warmth-loving species, those of cooler habitats, and the Filmies. The last-named are in splendid condition, and include fine specimens of Todea Moorei, the Killarney Fern, and other species. In regard to the Ferns generally, the collection is especially rich in species, rather than in varieties, but many of the more distinct of varieties are there.

In the cool division we noticed nice specimens of the interesting water-plants Isoetes lacustris and Eriocaulon septangulare (the Pipe-Wort), both of them growing a few inches below the surface of the water.

Succulent-house.—There is a very fine collection of succulent plants, and these are exclusively the occupants of two of the structures. We noticed a magnificent example of Epiphyllum Gärtneri; it was grafted along the stem of a Pereskia that reached a considerable distance up the rafter of the house, and the growths of the Epiphyllum are better than we have ever seen this plant. There are several capital plants of Stapelia gigantea, but unfortunately they were not in bloom. Senecio Gunnisii is an exceptionally curious species, the growths being quite snake-like in form; it has an erect flower-spike and red blossoms. Mr. Lynch said that this plant is to be figured in the *Botanical Magazine* shortly, as is also a white-flowered, rather insignificant-looking Crassula named C. abyssinica. There were many other interesting plants in this house as in the others.

The Conservatory. — Although decorative gardening is not the primary consideration in a botanic garden, and Mr. Lynch's aims are in sympathy with those of the botanist, he had a very gay conservatory. Amongst other plants in bloom or with fine foliage, were Pelargoniums, Ixias, Babianas, Tritonias, Arisæmas, Hippeastrums, some of the newer Cannas, Celsias, Exacum affine, Tropæolums, &c. Some of Mr. Lynch's hybrid Cinerarias were here, and in other houses. We have already figured some of these, and a batch of them are now in cultivation for exhibition at the hybrid conference to be held at Chiswick in July.

The Stove. —In this structure we noticed, among a general collection of plants, very good specimens of Caladiums, Dracæna Godseffiana, Asparagus Sprengeri, Hæmanthus, Acalypha hispida, and Begonia × President Carnot, a carmine-rose flowered variety, raised, we believe, by Crozy, from B. Olga and B. coccinea. It is one of the most handsome of shrubby Begonias, and cannot be too strongly recommended for cultivation in a greenhouse with an intermediate temperature.

Orchid-house.—The collection of Orchids is not very extensive, but includes a considerable number of the most ornamental species and others interesting to the botanical student. At the entrance Mr. Lynch has erected in cork an imitation of a tree, and from this some of the epiphytal species are suspended; and Tillandsias grow in pockets that occur on the branches. When Cattleya citrina and other species are in bloom no doubt a pretty effect can be thus obtained. In the same house is cultivated a very good collection of Nepenthes and other pitcher-plants; there were particularly good specimens of N. Curtisii, N. Veillardi, remarkable for having a white line under the ring of the pitcher; and N. Mastersiana. The Sarraceniaceous plant, Heliamphora nutans, was observed under a glass case. It is a herbaceous perennial plant, with radical, tubular leaves, having a somewhat oblique mouth, lined with deflexed hairs. The flowers are borne upon a scape, and are nearly white.

The Out-of-door Grounds.—The gardens, which are some 17 acres in extent, possess many interesting and gratifying features. The Bog-garden for instance, a photograph of which was reproduced in *Gardeners' Chronicle*, November 4, 1882, contains and is surrounded by many plants of botanical interest suitable to such conditions as the dampness affords, and the rockery, figured at same time, is attended to with the same care given to the plants indoors. Conifers not unnaturally refuse to thrive at Cambridge, but there are exceptions to this, Biota pendula and Sciadopitys verticillata are capital specimens. By the side of the lake we noticed Asimina triloba, the North American Papaw, apparently thriving well; and also near to the lake were the Toothworts, Lathrea squamaria, and the less common L. clandestina in flower. The first-named species is common in certain localities in Britain, including the Cardiff district of South Wales, where we have seen scores of the racemes in the pleasure-grounds of Cardiff Castle. L. clandestina is found chiefly in the West and South of France, and is usually upon the roots of the Willow. It has a racemose inflorescence and erect flowers, differing from the other species in having a longer lip to the corolla, and angled seeds. It is figured in *Bot. Mag.*, t. 7106, and the differences are there described as very considerable. In colour the flowers are pale violet, and are prettier than those of L. squamaria. At Kew and at Cambridge, L. Clandestina is growing upon the roots of a Willow.

Not far from the lake is a Bamboo-garden, and this is also of much interest, being the forerunner of larger but similar developments elsewhere.

Carex paniculata, with its curious stem of closely-bound roots, and many kinds of bulbous and other plants, are to be seen in the Wild-garden.

But our time did not permit of us dwelling longer amidst the beauty of the grounds; and returning again towards the glass structures, our attention was attracted to a number of the more hardy succulents, growing amid some stones around the walls of the house. Agave utahensis has been in this position for nineteen years. Opuntia Engelmanni, too, was present in extra good specimens.

Mr. R. Irwin Lynch in September next will have been at Cambridge twenty years, and is, of course, an old "Kewite." How he has succeeded in maintaining the tradition and in increasing the reputation of these gardens is shown by the great esteem in which he is held by all connected with the University, and by visitors to his most interesting establishment.

Since Mr. Lynch removed to Cambridge, the whole of the well-appointed glass structures at the present time existent there have been erected, and excepting certain features of the Palm-house and temperate-house, these have been built in every detail in accordance with designs prepared by him.

The collection of plants at Cambridge contains about one-fourth of all known genera, and in recent years a very large number of new species have been figured from there in the *Botanical Magazine* and in our own pages. Indeed, what has been achieved at Cambridge in twenty years, can only be fully appreciated by those who were acquainted with the gardens previous to 1880, and who, therefore, can compare the conditions that then obtained with those so much admired now. That the botanical requirements of the University are fully met may be judged when it is stated that there were furnished from the gardens during last year as many as 137,000 specimens.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM HALLI.

Two distinct sections of this fine Ecuadorean Odontoglossum, the one having a white ground-colour to the lip and the other a yellow ground, are easily distinguishable; but in each section the variation is also very remarkable, and the fact has been well demonstrated by the several extraordinary forms which have bloomed in the collection of Joseph Broome, Esq., Sunny Hill, Llandudno (gr., Mr. Axtell), who again sends some beautiful examples, one of which is remarkable not only for its great size and fine colour, but for marked structural difference in the form of the labellum, which is 2 inches in length and 1 inch across. A striking feature of the lip is the comparative narrowness of the base, and the dilatation of the front portion into an almost cordate blade, fringed in the usual manner. The sepals are purplish-chocolate tipped with yellow, and with a few yellow markings. The petals are yellow, with numerous reddish chocolate-coloured spots, which become larger towards the clear yellow apex. The lip is of a yellow tint, with some red markings on the spiny crest; a long, irregular blotch of dark red colour runs down the centre, and a chain of red markings inside the yellow margin.

It is satisfactory to find exceptionally rare varieties in Mr. Broome's collection, as they are not likely to be lost, a fact proved by the presence in his collection of the original plant of Odontoglossum crinitum which furnished the late Professor Reichenbach with the first living flowers sent many years ago by Mr. Broome from his collection at Didsbury, Manchester.

SACCOLABIUM AMPULLACEUM AND S. CURVIFOLIUM.

Neither of these species are so showy as S. retusum or S. guttatum giganteum, with their lengthened spikes of white and rosy-purple shell-like flowers. Still, S. curvifolium with its scarlet-orange flowers, borne on erect spikes, reaching in some cases 8 to 10 inches in height, is by no means valueless in the Orchid-house. S. ampullaceum when well grown has dense, erect, densely-flowered racemes, 6 to 8 inches long, and the beautiful deep rose colour makes them very attractive These two species flower in May and June, and by careful management the flowers will remain perfectly fresh for three or four weeks, and no harm will be done to the plants by permitting the blooms to remain for that length of time. These species are best when grown in baskets, with but little moss about them, and suspended from the roof of the East India-house, in a part where the light is fairly strong, but at the same time free from direct sunshine. I have found these plants succeed where the air was fairly dry; and the moss or compost in the basket should not be kept in a constantly wet state. If they were grown in a Croton-house or Pine-stove, and shaded from direct sunshine, I am sure many who now have small or dwindling plants would find them strengthen considerably. Of S. curvifolium, there is a yellow form, not, in my opinion, so good as the original; and of S. ampullaceum there is a variety named moulmeinense, that has larger flowers of an intense rose colour, set on longer and more dense spikes. The leaves of this variety are dark green, furnished with many small spots of brown, chiefly found on the upper sides of the leaves. *W. S., Exmouth.*

ASTER NANSHANICUS.

THIS lovely Aster (fig. 120, p. 331), described by C. Winkler, from north-western China, flowers from June until late in October. It is the earliest of this group, so far as I know of. The rays are pale lilac, like those of Aster alpinus, and the disc is of a bright yellow tint. The plant, which is much branched, grows about 2 feet high, and of the same diameter. It flowers in a loamy soil, as well in the brightest sun as in the shade of large trees. Seedlings from June sowings flower the next summer. The small rays may, I think, by due selection, become broader, as it is a species that varies very much. *U. Dammer.*

SOME NEW RHODODENDRONS.

RHODODENDRON DILATATUM.—This species is one of the Azalea section of the genus, and is one of the latest new plants introduced from Japan. It flowered at Kew in the spring of 1898, but not well; this year, however, it has improved, and we are now enabled to judge better of its value. It greatly resembles R. (or Azalea) rhombicum, and the Japanese botanists have confounded the two species under one name. It has the same rhomboidal or lozenge-shaped deciduous leaves, arranged in verticils of three, and the flowers are of the same shade of bluish-purple, but they are larger in R. dilatatum, and about 2½ inches across, appear three weeks earlier, and above all, they are distinguished by the stamens, numbering five, to each flower; whereas in R. rhombicum there are always ten. Another distinction is afforded by the capsules: in the present species they are glabrous, but furnished with scattered glands; whilst in R. rhombicum they are covered with greyish hairs. In garden value this species will, no doubt, equal the very beautiful but still rare R. rhombicum, of which a fine specimen is now charmingly in flower at Kew. It is remarkable that two species bearing so close a resemblance to each other should differ so markedly in the number of stamens—a character on which the older botanists relied for differentiating Azalea and Rhododendron. R. dilatatum is a native of the Senano province of Japan. A figure of it has been made for the *Botanical Magazine*.

R. Przewalski. — The number of species of Chinese Rhododendrons unknown to cultivation in this country, except by dried specimens, is very great; almost every year sees one or more added to our collections. Quite recently this species has been introduced to Kew by way of St. Petersburg. It is one of the true evergreen Rhododendrons, and appears to have been collected first by Przewalski in the Kansu province of China, in 1872. It has not yet flowered here, but its flowers are white, and produced twelve to fifteen together in a corymbose raceme, the corolla being campanulate, with five roundish emarginate lobes. The calyx is small and glabrous. The leaves are leathery, and 3 to 5 inches in length, and the species attains a large size. Of its possible value in gardens nothing can yet be said, but it is doubtless quite hardy. It may be interesting to place its introduction on record.

R. rubiginosum.—One of the names that will always be intimately associated with the discovery and introduction of Chinese Rhododendrons is that of the Abbé Delavay. It is to him that the credit of the first discovery of this species belongs. He

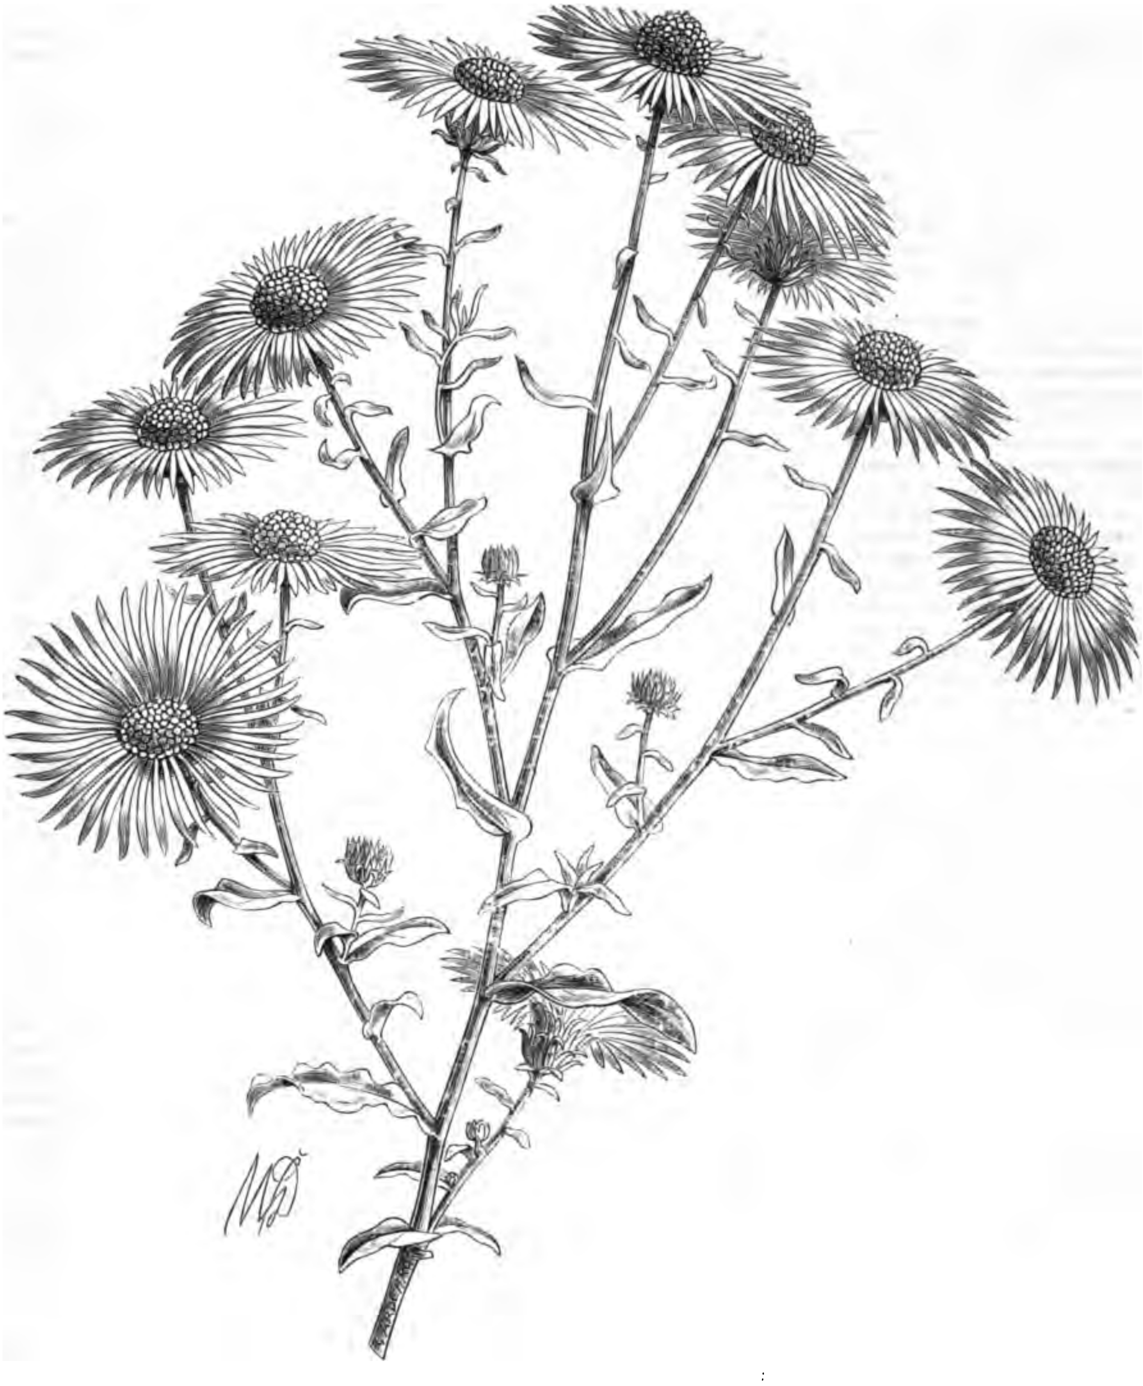

FIG. 120.—ASTER NANSHANICUS (C. WINKLER). NAT. SIZE. (SEE P. 330.)

*

found it about fifteen years ago on the Tsang-chan mountain in Yunnan, China, at an elevation of 8,200 feet above sea-level. It flowered for the first time at Kew last year, when it was figured in the *Botanical Magazine*, t. 7621. It is just now passing out of flower for the second time, and, judging by this year's experience, it promises to be a really useful addition. The plant is at present a bush 2 feet to 3 feet high, of compact and rounded habit, the leaves being 2½ inches to 3 inches long, dark and glossy above, but covered thickly beneath with rust-coloured scales. The flowers appear in small, terminal trusses of four to eight blooms, the funnel-shaped corolla being 2 inches across, rosy-lilac, spotted with maroon. During the middle and latter part of April it was literally one mass of flower, and was not injured in the least by frost. It has much the same stature and general character as the North American R. punctatum, but comes into flower some weeks earlier. This year it outrivalled all the dwarf Rhododendrons flowering at the same time out of doors.

R. yunnanense.—Of all the new Chinese Rhododendrons that have yet flowered in this country, it is probably R. racemosum, shown so prettily every spring by Messrs. Veitch, that takes one's fancy most; but next to that, I think this species is the most attractive. As its name indicates, it comes from the Chinese province of Yunnan, where it was discovered by Delavay. It is just coming into flower now for the third time at Kew, but owing to insufficient material in the herbarium there, was not identified till last year, when M. Franchet recognised it as the species described by himself from Delavay's dried material, and named as above. It is a shrub with slender branches, and is rather thin and open in habit. The leaves, which average from 2 to 3½ inches in length, are lanceolate, the upper surface being furnished with short, bristly hairs, and the lower one, which is somewhat glaucous, with glandular dots. The flowers are in a terminal corymb, four to six together, each flower 2 inches across, of the most delicate lilac shade, marked with two clusters of blood-red spots. This Rhododendron may become popular in time, for it is evidently quite hardy, can be increased easily by cuttings, and has a delicate beauty quite distinct from any other. It is at its best during the latter part of May. *W. J. Bean.*

SOUTH AFRICAN NOTES.

JOHANNESBURG.

(Continued from p. 293.)

Ten years ago, when these gold fields began to develop, new-comers beheld a tract of country as flat as Salisbury Plain, and quite destitute of timber trees, for the only trees the old Boer settlers planted were Weeping Willows, and these close to their houses. It was reported to be too cold for Australian trees, and some hesitation was felt in planting them. Beginning with a few Gums and Wattles, these grew so well, that soon large plantations were set out, with the result that there are to-day millions of thriving trees, 50 to 70 feet high, which have already given a considerable return in firewood and fencing-posts. This is very much better than burning dry cow-dung, which was the primitive Dutch fuel.

The growth of some trees is very remarkable. Recently I thinned out a small plantation of Eucalyptus viminalis, which I planted five years ago at 6 feet apart, the young seedlings being then 6 inches high. I carefully measured one tree; it was 60 feet high, and 1 foot in diameter close to the ground. The Blue Gum does not grow quite so fast as this, but I believe the timber is more valuable. The Silver and Black Wattle and Blackwood, viz., Acacia dealbata, A. mollissima, and A. melanoxylon also do well and soon grow into timber, but it is rather cold for Grevillea robusta and Casuarina tenuissima. Amongst Pines, P. insignis comes first in rapid growth and perfect health, then follow P. Pinaster and P. halepensis, but Pinus pinea does not seem happy, and P. sylvestris refuses to grow. Larches, Spruces, Yews, and Silver Firs are not successful—the air seems too dry for them. Nearly all the Cypress tribe thrive, particularly C. macrocarpa and C. Lawsoniana, but tender species like funebris are very slow. Junipers do well, particularly J. bermudiana. [What is this? Ed.] Cedrus Deodara makes a very fine tree indeed; if our Government ever establishes State forests this is a tree which should be largely planted. Sequoia gigantea does very well, yet, strange to say, in the warmer parts of Natal it is a failure. Japan Conifers do not seem at home in our dry air, but most American and Chinese Arbor-vitæ promise well. I have not seen an Araucaria imbricata or a Cedar of Lebanon, but a few large Cunninghamia sinensis are to be met with; Taxodium sempervirens and T. distichum grow very slowly.

Of deciduous trees, the English Oak does very well if sheltered from wind when young. American Oaks are just being tried. Ashes, Birches, Maples, Ailanthus, Planes, Alders, Paulownias, Catalpas, Walnuts, Tulip-trees, Poplars, and Elms we find grow fairly well if care be taken to afford them a deep and somewhat moist soil. Beeches, Limes, and the Horse-Chestnut do not thrive. The Spanish Chestnut promises very well. It must be borne in mind that the above remarks apply to my own locality, which is 6000 feet above sea-level. Lower down very many valuable timber-trees could, I have no doubt, be grown with success. So far as tested, the timber grown here is dense and hard, and many of the trees bear good seed in quantity at an early age.

In the low "veld," between 2000 ft. and 4000 ft. elevation, great natural forests of evergreen-leaved sub-tropical trees are still found, comprising such genera as Podocarpus, Calodendron, Bauhinia, Olea, Oreodaphne, Myrsine, &c.; but these would never withstand our severe winter.

The Transvaal is somewhat larger than Great Britain and Ireland, yet outside a ten-mile radius from where this is written the country is little better than a wilderness, except in a few spots where intelligent men have settled. I have for the last eighteen months in the columns of our leading paper urged the Government to establish state forests; but no one seems to pay the slightest attention, and, like Dean Hole in his *Book about Roses*, I have been "perplexed and pained by their dogged, strange reluctance to follow the very best advice."

When the old Boer settlers began to "trek" into this country, sixty years ago, from the Cape Colony, they brought in their wagons Apricot, Peach, and Almond-stones (but no Plums or Cherries), Fig, and Apple and Pear suckers, Quince, Pomegranate, and Vine cuttings, and forthwith they planted and watered the same. The result I have seen in old orchards—seedling Apricot and Almond-trees, from whose trunks you could cut 12-inch planks; but the fruit is very small, and inferior in quality. I have seen Fig-trees of such a size as would astonish even a Californian fruit-grower. Seedling Peaches, yellow, white, and red-cheeked, bearing very large and delicious fruit. Apples of very inferior varieties, but the trees growing to a huge size. Hedges of Quinces and Pomegranates bear superlatively fine fruit. There are no Plums or Cherries, and very few Nectarines. Huge Pear-trees of one variety only—Saffrano or Cape Saffron. Lastly, there are one or two hardy varieties of Vines, whose fruits are able to withstand the rains, which fall at a time when the berries begin to colour.

An Opportunity for Development.

Thus it will be seen that there is vast room for improvement, for until about ten years ago grafted fruit-trees were seldom planted in this country. A new race has entered the Transvaal, who ask for, and are willing to pay good prices for, really good fruit, yet to-day we see in our shops Cape Plums, Californian Prunes, American-canned Peaches, Australian jams, and even Tasmanian Apples, which last are retailed at 3s. per dozen! Again and again I have urged by example and precept the introduction of a better class of fruits, such as Japan Plums, Californian Prunes, improved hybrids of North American Grapes, Persimmons, and good-worked varieties of Peaches, Plums, Pears and Apricots, but up to now I cannot see that much is being done. The above-named fruits thrive in the higher and colder parts of the Transvaal; further north, and between 2000 feet and 4000 feet elevation, Lemons, Mandarine and other Oranges, Citrons, Gourds, Custard-apples, Loquats, Melons, and Tree-Tomatos bear abundantly. Lower down, again, near Barberton, at 1000 to 2000 feet, we find Bananas, Pine-apples, Mangos, and every tropical fruit. In this locality, owing to the severe winters, insect pests are not very troublesome.

In everything that relates to the collection and spreading of information about fruit-culture—for instance, what is being done in California and Australia—we are living in the dark ages. There is not a botanic garden, model farm, experimental station, fruit-growers' association, farming or gardening paper in the Transvaal. The methods of the old Dutch fruit-growers are primitive enough to raise a smile of compassion from father Adam. At the Cape, considerable efforts are being made—in which Mr. Rhodes is taking a good share—to raise a superior class of fruits to supply the European winter market, i.e., from December to April. We have no such high ambitions at present; the object being to supply the local demand, which is the best in South Africa. I commend fruit-growing to the attention of practical men who think of coming to this country.

Wonderful as the progress of the Transvaal has been during the last ten years, yet really and truly it has only been scratched over. Very much of the mineral wealth has been untouched, whilst its horticultural resources are still lying dormant. It is a country of infinite capabilities, and those who have known it longest have the greatest faith in its future, in spite of the unsatisfactory state of politics at the present time. *R. W. Adlam, Joubert Park, Johannesburg, Transvaal.*

KEW NOTES.

Hippeastrum Arechavaletæ.—A new species of Hippeastrum was described by Mr. Baker in the *Kew Bulletin* last year, p. 226, from material supplied by M. Cantera of Montevideo, Uruguay. A plant of it is now in flower in the T range at Kew, and a figure will shortly be published in the *Botanical Magazine*. In general characteristics it comes very near H. vittatum, as figured in the *Botanical Magazine*, t. 129 (1790). The only difference I can see is in the margins of the segments being crimped in H. vittatum, whilst in H. Arechavaletæ (a terrible name!) they are plain. The plant at Kew has a round dark brown bulb, 2 inches in diameter, a short, thick neck, and six leaves, 18 inches long by 1¾ inch wide. The scape is cylindrical, glaucous-green, 2 feet high, and it bears an umbel of three flowers; pedicels, 1½ inch long; corolla narrow, funnel-shaped, 4 inches long, 2½ inches across the mouth, white, with a pair of broad broken bands of crimson running parallel almost from base to apex of each segment. It is a pretty plant, although it falls short of the breeder's ideal of a good garden Hippeastrum. The name is in compliment to Professor Arechavaleta, a botanist in Montevideo.

Clianthus Dampieri.

A plant of this beautiful greenhouse shrub is now flowering freely at Kew, where it is planted in a border of light loamy soil, and the stems trained against the roof-glass in an airy, sunny greenhouse. It has grown here with exceptional vigour, covering a space a yard square in less than two years, and it is now bearing a dozen large bunches of flowers. Usually this plant is grown in a pot of sandy-peat soil, but it rarely grows to flowering size, owing, it is thought, to its objection to anything like a heavy watering. Judging by the behaviour of this Kew plant, what it likes is plenty of root-room, and that uniformity of conditions which can be easily supplied in a well-drained border. In the same house and under the same conditions, the beautiful Californian Lathyrus splendens, figured in the *Gardeners' Chronicle*, 1897, vol. xxi., p. 315, has been a success for three years, and is again now flowering freely. *W. W.*

GUNNERSBURY PARK AND HOUSE.

The two domains, Gunnersbury House and Gunnersbury Park, Acton, are now substantially one. This is a reversion, no doubt, to the order of things which prevailed at the time when the Princess Amelia occupied them. The original mansion occupied by the princess was built for the celebrated Serjeant Maynard in 1663 by Webb, a pupil of Inigo Jones. In 1761, it was purchased for the Princess Amelia, after whose death it was sold in 1788, and some years afterwards it was entirely pulled down. It may be assumed that Webb's mansion occupied a site a little way north or east of the present mansions, and, perhaps, midway between the two, for the old wine-cellars, still intact, occupy some such position, but nearest to Gunnersbury House.

After the removal of the original mansion, the estate appears to have been divided, and one portion—about seventy acres—passed into the possession of Alexander Copland, Esq., who erected a villa, "surrounded by extensive and ornamental gardens and pleasure-grounds, which comprise about seventy acres." This would appear to have been the Gunnersbury Park, which subsequently became the property of Baron Lionel de Rothschild, who made considerable additions to the estate by subsequent purchases, and laid out a very large piece of ornamental ground, extending almost to Kew Bridge, and which is now known as the Potomac. The other portion of the estate, presumably that occupied by the mansion and grounds of Gunnersbury House, became the property of Stephen Cosser, Esq., who erected a villa about 1810. Eventually it passed into the possession of Thomas Farmer, Esq., who was formerly the Treasurer of the Wesleyan Missionary Society, and on the west side of the mansion he erected a hall as a museum, and filled it with momentos of missionary operations. H. J. Atkinson, Esq., married a Miss Farmer, and sold the estate to the Rothschild family.

An Ivy-clad brick wall which divided the two estates has now been removed, and the carriage-drive from the main entrance in Gunnersbury Lane to Gunnersbury Park is extended in an eastern direction, and by means of a bold curve is continued to and unites with the drive to and from Gunnersbury House, which has both entrance and exit on the east side, and so a complete carriage connection between the two mansions is secured. The construction of this drive demanded the removal of many large shrubs and some trees, but the subjects removed have been utilised in other parts of the grounds. Beyond the ornamental water on the Gunnersbury House side, Mr. Hudson has made an imposing garden of semi-aquatics, and carried out other improvements in various parts, now approaching completion.

The effect of these improvements, in the direction of adding seeming extent to the grounds of both the park and the house, is something astonishing. To one standing upon the terrace of the mansion of Gunnersbury Park, and looking eastward, the grounds of Gunnersbury House appear to reach away to an unlimited extent, because the wall forming the eastern boundary is quite hidden from view; an unbroken carpet of verdant lawn stretches away to the boundary on every hand. One standing on the terrace of Gunnersbury House notices the same, only that the vista is longer and wider to the eye. Fine trees that were hidden from view by an under-growth of shubbery are now individualised. Mr. Reynolds has worked out, on his side, certain details of improvements, that small in themselves yet largely assist the general effect. One result of these improvements is that Gunnesbury will become the residence of members of the Rothschild family for some portion of each year.

In reference to matters of practical gardening, both places are full of interest. Mr. Reynolds is making an experiment with plants of Tropæolum speciosum in pots, for the purpose of training them on trellises. May he succeed in flowering it abundantly!

The Peach-wall, in a line with the Fig-cases, has been covered with glass, and within it there is promise of good crops.

Evidences of Mr. Reynolds' attention and forethought are met with throughout the pleasure-grounds. Gunnersbury is seen to great advantage at all times, but chiefly in May and June. *D.*

Fruit-trees in Pots at Gunnersbury House and Syon House.

Recently I made a visit to Gunnersbury House, in order specially to gratify my curiosity in regard to the fruit-trees in pots. "This has been," said Mr. Hudson, "the worst season for the setting of fruit that I have ever experienced, and this, too, with a mild winter, which is difficult to understand by those who do not force fruit very early, and have a much clearer atmosphere to deal with than that of West London." I have no wish to publish my own failures, but when whole houses of Vines and Peaches are lost during a few days' fog, it will be understood that it is not a happy position to be in;" and I was rather anxious to see how Mr. Hudson's pot-trees had fared. The earlier-forced trees this season are not carrying nearly so good a crop as in former years. The trees were full of bloom, but it failed to set satisfactorily. For this reason, the Gunnersbury House fruit-trees will not appear at the Temple Show. Now, had this show been some weeks later, there could have been a grand lot of trees staged from thence, as these later-flowering trees were not affected by fogs.

In the earliest house the new Nectarine Cardinal is the favourite variety, and some of the trees had been cleared of their fruits; still, as a whole the crops on the various trees were lighter than usual. There is a fine lot of trees of this variety, and there can be little doubt as to its good qualities as a forcer, but it is not proof against weeks of foggy weather. In this locality we suffer much in January and February with fogs, which in the latter month cause much loss of bloom on Peach and Nectarine trees, and cause the bunches of Grapes to curl up, and turn of a yellow tinge. Unfortunately, as late as March 28 we had in this locality fogs, the last one destroying a large houseful of Muscat Grapes at Syon just as they were coming into flower. The splendid tree of Lord Napier Nectarine at Gunnersbury House, which fills a forcing-house, is not nearly so good as usual owing to the fogs and lack of light; and the earliest Peach-trees in pots at that place have suffered similiarly. The best this year are early Grosse Mignonne and Dr. Hogg; the latter though not a very early variety is much liked for pot-culture, and is very fine in later houses. As a variety that withstands hard forcing without injury, Early Beatrice is excellent here, although when grown at Syon in the open air I do not like it, the fruits being too small, and prefer Waterloo. With the high cultivation afforded pot-trees in general, Mr. Hudson gets remarkably early nice fruits of this variety. In the early-house, which has a span roof, a shelf of Auguste Nicaise Strawberries was noted in full crop with fruits mostly ripe—and such Strawberries! many of them weighing 2 ounces apiece.

Leaving this house I entered a Cherry-house filled with trees in pots. The later varieties were ripe, and though affected by lack of sunlight the trees had blossomed during a spell of fine weather, and were comparatively none the worse; the trees were very fine ones. Bigarreau de Schreken is much liked here, and some of the fruits were as large as Walnuts, and good in colour; Governor Wood, a grand cropper, is grown largely; and the trees of Early Rivers, which is much liked, were cleared of fruits. Guigne Annonay is considered to be one of the best forcing black Cherries, a very rich-flavoured fruit. Of other varieties I may mention Frogmore, Early Bigarreau, and Emperor Francis, the latter a very fine Bigarreau. In this house some trees had been planted at the foot of the pillars supporting the roof, so as to train them in cordon form along the ridges of the house. These trees will not obstruct the light, and they will be profitable. In the second early house were splendid trees of Plum, Peach, and Nectarine. The varieties of Plum are Early Rivers, the fruit of which was nearly ripe and the crop excellent; others consisted of Jefferson, Early Transparent Gage, and Reine Claude de Bavay, also a Gage, all of which will be ripe shortly. Plums are certainly reliable fruits under pot-culture, blooming as they do at different periods. There is a row of Early Rivers Nectarine trees occupying one side of the house, quite young trees, averaging twelve fine fruits apiece. In this house, the varieties Pine-apple, Humboldt, Advance, Rivers' Orange, and Victoria, the first-named being the favourite late variety. Dr. Hogg Peach is largely grown, and good crops were noted of Sea Eagle, Early Mignonne, Crimson Galande, and the Nectarine Peach, the two latter being much liked for late use. A Strawberry-house divides the next or later division of trees in pots, and the plants were finishing a heavy crop of fruit. Royal Sovereign, though not so large as the Auguste Nicaise, carried a fine even crop; and Vicomtesse Héricart du Thury is grown in some quantity for its fine flavour.

The trees in the late house are just as remarkable for their heavy crop of fruit as the earliest is for their light one. I noted Ickworth Impera-trice, Late Transparent, Late Rivers, Golden Drop, Grand Duke, Monarch, Guthrie's Late, and Golden Esperen. The Peaches most noticeable were Nectarine, Sea Eagle, Golden Eagle, Osprey, Barrington, and Stanwick Elruge. Figs in pots have been ripe since February, and are a specialty here. Large numbers are forced early and late; the early kinds are now making their growth for the autumn—a remarkably healthy lot of trees. As most gardeners know, the forced Fig-tree is apt to get leggy and unsightly, so the gardener at Gunnersbury House cuts them hard back after the fruiting is over, and places them in a small house or pit, where, with generous treatment, they make shapely fruit-bushes, fit for bearing another season. The St. John and Pingo de Mel are the varieties employed.

Another house or pit is devoted to other varieties for fruiting in October to December, the varieties being Negro Largo, Nubian, Grosse Verte, and Bourjassotte Grise, all robust and healthy trees. A north house or lean-to is filled with Pear and Apple-trees in pots, and this house is also used at times for retarding fruits. I noted fine trees of Pitmaston Duchesse, Doyenné du Comice, Princess, Marie Louise d'Uccle, &c., well set with fruits.

No note on pot-trees would be complete without referring to the splendid lot of fruiting Vines in pots. I have never seen better Foster's Seedling, and the canes had carried a heavy crop of bunches. The Black Hamburghs were good. *G. Wythes.*

CORFU.

The following communication contains the impressions of a member of the medical profession who made a pleasure-trip to the island in March last, which may be of interest to some of our readers. "We may premise that the people, although for a long period of time they have been in connection with us, are very simple in their mode of life, and hotel or other accommodation away from the town of Corfu is, according to western ideas, non-existent. Those who are not prepared to exist on the simplest fare would do wisely to take sufficient stores with them to suffice for the length of their stay, and some one to cook the food, if they do not care to undertake to do that themselves. The climate in the early months of the year is very pleasant, but the nights are cool, and even some snow fell during the visitor's stay. The sleeping arrangements leave much to be desired, the bedding which is generally obtainable having been found very insufficient during the cold weather prevailing in early spring.

"The island of Corfu is divided into three zones by two ranges of mountains, rising about 2000 feet above sea level, rocky and naked. The greatest breadth is twenty miles, and the length thirty-eight miles. The valleys show great fertility, and they are watered by many streams. The southern zone is sparsely populated, and nothing but Olives, a few Orange trees, Vines, and Myrtle were noted. Daisies, Lilies, and much Holly were plants that are found everywhere. The northern zone we did not go into, but I should think it was very similar to the southern from what we saw from the sea, and looking down from the northern range of hills, excepting that it is more mountainous. The central part, in which is the principal town of Corfu, is much the more level, thickly populated, and fertile. The chief features were a great many Orange groves, Olive plantations, and Junipers were remarked; Aloes and prickly Pear (Opuntias) forming the hedges; the Fig, Almond, Eucalyptus Globulus, which does very well, wild Roses, Ericas, Date Palms (these do not fruit), Cacti, Arums, Hyacinths, Violets, Lilies, Holly, Ivy, Nasturtiums, and Pinks. Lombardy Poplars and Plane trees were remarked. The vegetables consisted of Cauliflowers, Potatos, Lettuce, and Globe Artichokes. The town was planted with trees which grew well, but there was none along the country roads.

"We noted but little gardening in the town or suburbs. A few gardens were noticed in which were Roses, Bananas, Strawberries, Hyacinths, Arbutus, Myrtle, and Stocks. No window-boxes or creepers on the walls of the houses were observed.

"In the royal gardens, which are under the management of Chevalier Josef Bouzzai, were noted the following as trees or bushes:—Laurus nobilis, Mespilus japonica, Pittosporum Tobira, Oleanders, Robinias, Arbutus Unedo, Chamærops humilis, Cedrus Libani, Populus discolor [?], Thuia plicata[?], T. pyramidalis, Araucaria imbricata, Ailanthus glandulosa, and other common subjects. We spent a fortnight very pleasantly in exploring much of the island, and would recommend it to those who may be contemplating a short outing, as being at the least for the present out of the ordinary track of the tourist."

AUSTRALIAN *v.* SWEDISH TIMBER.

"ONCE upon a time," writes a correspondent, "being engaged in getting up figures respecting the use of Australian timber in this country for road-paving, I applied to a certain Agent-General, who suavely referred me to a timber-merchant in the East-End, as being the gentleman entrusted with the business of that department for this country. 'He would furnish me with all the information that could be given;' and so it came to pass that it was soon found no information would be given; it was not to the advantage of the firm in question to furnish such figures, and so forth. Occasionally, however, we—in spite almost of the Board of Trade Returns—get at the value of Australian timber used here as compared with Swedish; and only the other day the St. Pancras Vestry issued a report, concerning, amoug other matters, the use of Australian wood in the streets of that parish. It appears that, seven years since, a large portion of the Euston Road was paved in sections with Swedish and Kauri Pine-blocks; but the Swedish blocks broke up so rapidly, that they had to make way for the Jarrah timber. It is found that the hard Australian wood lasts longer, and decreases splashing. Were it not that an agreement exists with the Tramways Company for the maintenance of sundry long roads by the use of granite setts, the whole area would be laid down in blocks of the above material. Doubtless an early agreement will be arrived at by which Australia will win, and granite setts be put aside. *E. C.*

SUMMER-QUARTERS FOR CERTAIN EXOTIC PLANTS.

As a means of ensuring clean and healthy growth of many of the larger exotic plants, a great deal may be said for the practice of growing them in the open, when the temperature outside permits of doing this without injury to them.

Palms and strong-growing greenhouse Ferns are much benefited by passing a month or two in the open air. Among Palms which may be treated in this manner are Trachycarpus excelsus, T. Martiana (khasyana), Chamærops humilis, Erythea armata, Seaforthia elegans, Livistona chinensis and L. subglobosa, Phœnix spinosa, P. reclinata, and P. dactylifera. Palm-leaves lose their green colour under strong sunshine, and need therefore a moderately shady place. It would be found that if placed in such a position in the middle of the month of June, the petioles would be somewhat shorter, but stouter than those of indoor plants, the leaves broader and of a dark green hue, and the plant generally enabled to withstand with less harm the conditions prevailing in living-rooms throughout the winter. As many gardeners who grow Palms for dwelling-house decoration only have high houses for their Palms, the more compact, stocky growth induced by open-air treatment is a great advantage.

Ferns, the hardier evergreen species usually grown for decorative purposes, would "summer" outside very satisfactorily if placed under the shade of trees in a sheltered spot. Asplenium bulbiferum, Pteris tremula, P. umbrosa, and Gleichenias of sorts, among others, would grow very clean and hardy, and the vigour they would show would carry them safely through the winter and spring. Ferns at Isleworth grown in this manner last twice as long in good condition as those taken direct from the house. Portable Tree-Ferns would benefit by a short stay outside during very hot weather, as it is no easy matter for the gardener to keep down the insect pests which affect these plants throughout the summer. Dicksonias antarctica, squarrosa, and fibrosa, Cyathea medullaris, C. insignis, Alsophila crinita and excelsa, would all be better able to stand over the winter if the fronds were exposed to the open air, and thereby hardened somewhat. It would not be difficult to find nooks and corners in most gardens suitable for Tree-Ferns of the hardier group. Cyatheas and Alsophilas, from their natural habit of throwing up one or two fronds at a time, are frequently allowed to grow too late in the year, so that the fronds cannot thoroughly mature, and, as a consequence, they either rot or remain on the plant an eyesore for a considerable time; if moved outside in July or August for a few weeks, the plants ripen somewhat, and are cooler beneath the shade of a tree than if left in the house, unless it is shaded only during actual sunshine. By the process of ripening, i.e., hardening, the tendency to grow late in the year is considerably lessened. I have watched the Tree-Ferns at Kew in the temperate-house for three or four years, and have noticed that if late fronds are thrown up they rarely develop properly; in two instances the fronds rotted before they had uncoiled, owing to the foggy weather prevailing at the time, and in spite of careful cleaning out of the decayed frond the stem soon decayed likewise.

Among Orchids, such plants as Vanda Amesiana, Lælia anceps, and Oncidium incurvum do well outside, a moderately sunny place for the two former plants would suit them; a cool, shady place for the Oncidium. Oncidium incurvum is perhaps easy to grow in a cool-house, but to show how much better it grows outside I give the following measurements: the plant measures 2 feet through, and produced eight panicles, averaging from 3 to 4 feet 6 inches in length, with an average of from thirty to fifty secondary axes, bearing from four to eight flowers each. Roughly calculated, this would denote about 2000 flowers. It was put out in the latter end of June, and is generally taken inside towards the end of September.

Crinums.—C. scabrum, C. giganteum, C. latifolium, C. Moorei, and C. capense all do best outside under the shade of a tree (a Weeping Holly is used for the purpose at Isleworth); if grown in a house the whole of the summer, thrips do a great deal of damage to them, and it is scarcely possible to keep them down unless insecticides are used to a dangerous extent. Under the shade of a tree they grow well and produce fine flowers. It is not safe to place them in the open, as on clear cold nights radiation lowers the temperature to an unsafe degree, but under a tree radiation is much arrested, and on the other hand, an excessively high mid-day temperature is guarded against by the shade the tree affords. If thrips prove troublesome outside, as they have done this past few weeks, it is advisable to totally immerse the plants for a few hours. Places in the front of walls facing south are well suited for Phyllocactus, Cereus, &c.; plants in such places make stout well-ripened growths which flower freely, and rambling Cereus do best. The columnar ones, and Echinocactus are liable to injury on wet days from moisture lodging in the apex, always a susceptible spot with them. Many of the decorative Aloes, and the whole genus Agave, would do in similar places when not too bulky to remove.

Himalayan Rhododendrons, always difficult to keep cool enough during hot days, would be well suited if places could be found for them slightly shaded from strong sunshine and protected from drying winds by a shrubbery or fence. They grow much better in the open from June to September. A skeleton-house is really best for them with only thin blinds for protection from the sun's rays; they are never so happy as when grown in some old defile in the southern counties, between cliffs, cool and moist. Rhododendrons, like all the Ericaceæ, dislike a confined atmosphere, and would well repay the trouble of placing in some perpetually-moist and cool corner of the garden.

The beautiful Tecomas are very difficult to flower in a house, but if they are grown on one stem and treated as are Chrysanthemums, many of the plants will flower late in the autumn; the mealy-bug trouble with these plants is greatly minimised by this treatment—in fact, many of the South African and Australian hardwooded plants can only be grown well summered outside, among these may be mentioned Eugenias, Pimeleas, Grevilleas, Plumbago, Bankaias, Ericas, Mesembryanthemums, and the large number of Cape-flowering bulbs.

A plot of ground, covered with coal-ashes, fenced in from observation, and to protect from cold and drying winds, near a few big trees which would shade one portion of it most of the day, would prove a great boon to any garden for the purpose of growing plants during the summer. It is a practice in our garden to place together the plants whose requirements are akin, simply placing them on the coal-ashes, or plunging them in the same in batches by themselves. *Geo. B. Mallett, Isleworth.*

TREATMENT OF MILDEW ON VINES.

I HAVE just been successful in stamping out a very bad attack of mildew on Vines, the remedy being very hot water. The mildew occurred here for the first time two years ago, when a Lady Downes Seedling Vine became seriously affected. The usual remedies, sulphide of potassium in solution, dusting with sulphur, &c., stayed its progress for a time, but it eventually showed itself on most of the Vines in two vineries before the end of the season.

Last year the usual preventatives were used freely during the early stages of the Vine's growth, the pipes were painted with lime and sulphur, and sulphide of potassium solution was sprayed over the leaves and various parts of the houses two or three times a week till the Vines flowered. It was then discontinued until flowering was over; but in the intervening time mildew made its appearance all over the Vines in the houses previously affected, and the case from that stage became hopeless, in spite of continued syringing with the solution and dusting with flowers-of-sulphur, the crop being completely spoiled.

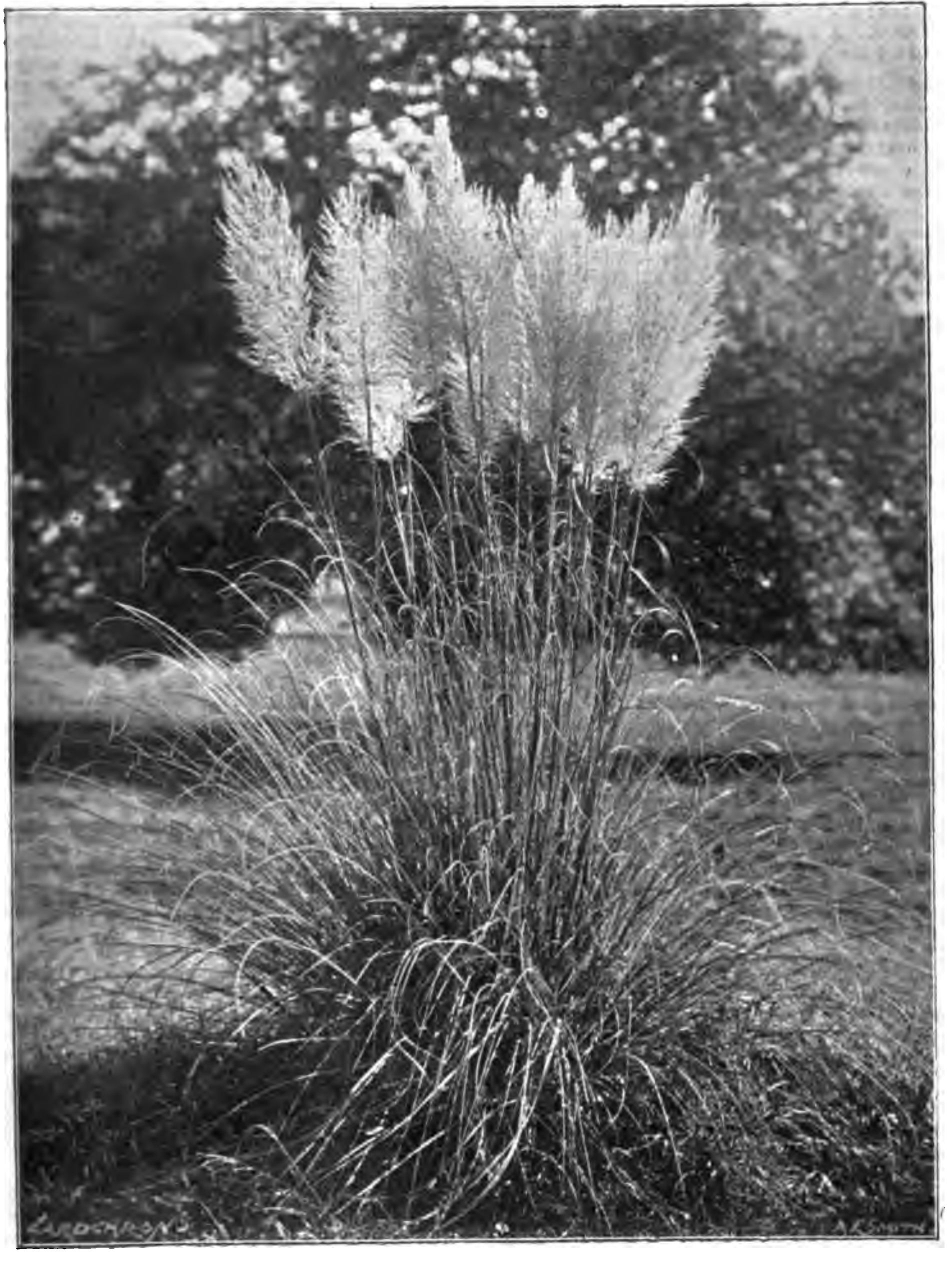

Fig. 121.—Cortaderia Lambleyi foliis variegatis, in Mr. W. E. Gumbleton's garden.

Early this year the vineries were thoroughly cleaned out, the top spits of the borders and walks were removed and taken away, and new soil replaced. The rods of the Vines were painted with a strong mixture of sulphur and potassium sulphide, but with little effect, as mildew again broke out in several places when the Vines in the early house had reached flowering stage. Drastic measures became necessary, and it was suggested to me to try hot-water syringed over the plants, at the risk of killing them outright. Water was accordingly heated to boiling-point a distance of 60 yards away, carried quickly to the vineries, and forcibly applied to the leaves scalding hot, the operator holding the syringe quite under the leaves, the barrel of the syringe being enclosed in a towel to protect the hands. The Vines were thoroughly soaked twice over, the surfaces of the borders being lightly watered also, to destroy any spores that may have fallen there. Singularly enough, not a leaf or flower was harmed, the young tender tips were also quite uninjured, whilst adventitious roots on some of the rods were quite blackened. Not a trace of living mildew was to be found the next day, but brown spots on the leaves showing where it had been were plentiful enough; these leaves were removed, and I have not seen a trace of fungus since. One subsequent application, especially directed at some Vines of White Tokay, was given as near boiling-point as was possible to use it, these Vines having been condemned on account of insipidity of flavour of the Grapes; these also show no signs of harm or check in growth. Another application was made to catch any spores that might be lurking about a few days after the first, in this case also the Vines came through the ordeal unscathed. Not only mildew, but a few examples of mealy-bug which had escaped the winter dressing were also killed. If hot water kills mealy-bug in this way, why should it not be effectual in killing Phylloxera, in one or all of the stages in which it is accessible? It appears to be worthy of experiment, either with hot water or with steam. The Vines experimented upon here for mildew were Muscats, Madresfield Court, White Tokay, and Lady Downes Seedling; in every case the Vines are growing freely, and the berries unharmed. *G. B. Mallett.*

CORTADERIA LAMBLEYI FOLIIS VARIEGATIS.

In regard to this handsome Grass, Mr. W. E. Gumbleton, to whom we are indebted for a photograph of the plant (fig. 121), writes as follows:—"I received this most distinct and beautiful variety of Pampas Grass many years ago from a nurseryman under the above name, for which I never heard any definite authority, and do not think I have ever since seen it offered by anyone else. It is perfectly hardy here (Queenstown), and of comparatively dwarf stature, and also of rather slow growth and tardy development, as though I have had it many years, it never showed its full beauty till last year, when it produced about twenty spikes, averaging 5 feet in height, and of a most distinct appearance; unlike any other variety known to me, its foliage is also prettily variegated with white."

VARIORUM.

Ramie Cultivation in Korea.—The Ramie stalk indicates its maturity for good fibre by turning yellow, and the leaves curl inwards at the end. In curing, the bark is loosened with the finger-nail, and is then stripped off with the aid of a bamboo-knife. This is done as soon as the stock is cut. As the decortication must be delayed, the stems are placed in water to prevent drying. This stripping is chiefly done by the women. The stripped bark is dried in the shade for several days, and is then made up into more or less compact bundles for packing upon pony back. The plant is propagated by transplanting the small rootlets that spring from the main root. This is done soon after the breaking-up of winter. Plants may be raised from seed, but the above method is preferred, and almost universally followed in Korea. The cultivation consists in digging about the plant just enough to keep it free from weeds; deep cultivation is not deemed necessary. There are three cuttings annually, in June, August, and again in September. Great care has to be exercised in making these cuttings, so as not to injure the young shoots that have sprung up, and upon which the next crop depends. Moist, rich loam is the most suitable soil for its cultivation. Stable-manure is used as a fertiliser. Warm temperature suits the plant. The United States Consul-General at Seoul says that there are two kinds of the Ramie plant grown in Korea, but he is unable to state whether they are distinct plants, or simply varieties of the same. "Moshi" is the name given to the carefully-cultivated one, and the fibres of this plant produce the silky threads made up into the highly-prized grass-cloth. The other plant, called "Sam," seems capable of growing almost everywhere. It is found in all gardens as a weed, and it will grow on rough hillsides and by water-courses. Neither barrenness of soil nor drought seems to kill it, though, of course, it is susceptible to care and attention. It is used for making the coarse fabric worn by the poorer classes in summer, and for the very extensive mourning costumes of all classes—a veritable "sackcloth." Moshi is used for the outer gowns of both sexes. No man or woman of any means in Korea is without one or more garments made from Moshi, which ranks next to, and is almost as pretty as silk. The same is, however, just as popular among the poor, and is indispensable for the three years' mourning periods that form such an important part of every Korean's life. Moschi once started, becomes a permanent crop, easy to raise and care for, and of much value. There are no Korean statistics as to the production of the fibre; but as there are supposed to be 12,000,000 inhabitants in Korea, it will be seen, from what has been said of the uses to which the Ramie fabric is put, that the production must be considerable. There is no export of either fibre or fabric. During the year 1897, an Austrian expert in Ramie visited Korea, with a secret process for the rapid handling of decorticated fibre, which he claimed to be able to turn into the perfected silk-like article in two hours. The Koreans were much interested in his proposition to establish a company in Corea, but declined to pay the large cash advance required for the use of the secret process. It is stated that the culture of Ramie could be increased in Korea indefinitely. "*Indian Gardening*," *April* 22, 1899.

NARCISSUS TRIANDRUS VAR. CONCOLOR.

In my notes which recently appeared in the *Gardeners' Chronicle* concerning hybrids of Narcissus, I suggested the probability of the varieties of N. triandrus, which have long been known as var. concolor and var. pulchellus, being wild hybrids of N. triandrus, and some form of N. juncifolius. In reply to inquiries I made, the Baron de Soutellinho of Oporto, better known to Daffodil collectors as Mr. Alfred Tait, has sent me some interesting information, from which I send extracts:—"As regards triandrus concolor I am rather puzzled; no juncifolius occurs near it (on the Sierra d'Estrella). The only Narcissus I can find in its vicinity is a Corbularia, but all the hybrids I have found of triandrus and Corbularia are more in the form of Corbularia, and are barren, whereas concolor seeds freely; so I can only consider it as a yellow variety of triandrus. The pulchellus, descendants of three bulbs which you sent me, never produce seed, but multiply by offsets, and at such a rate that, since 1887, when you sent me the original bulbs, I have raised several hundreds. This year I collected about 100 bulbs of concolor from a new locality—the banks of the River Antuâ (pronounced Antooang), near Estarreja, about 25 miles south of Oporto. It is strange that concolor varies so much—sometimes very like pulchellus, and sometimes nearly as pale as triandrus. The soil for concolor is decomposed argillaceous schist, with well rotted heather. N. concolor never grows on a granite formation, whereas triandrus grows only on such a soil."

In the same letter the Baron confirms my experience concerning the sterility of the hybrids known as N. Johnstoni, which he has never known to ripen a seed. *C. Wolley-Dod, Edge Hall, Malpas.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Cymbidium eburneum, and others.—The flowering season being now practically past, it will be necessary to attend to the requirements of these plants. The first named species produces few roots, and is very impatient of being disturbed. If a plant be doing well, remove therefore, merely some of the surface-soil and substitute fresh. Specimens which may be in an unhealthy condition, or in need of a larger receptacle, should be turned out and repotted into clean pots. The whole of the drainage material need not be placed at the bottom of the pot, but after putting some portion of it there add a little compost, and work in some crocks with this; and continue to mix these ingredients until near the surface, which may be finished off in the ordinary way. The compost may consist of good turfy loam and peat in equal parts, and a small portion of chopped sphagnum-moss. C. eburneum thrives in a warm part of the Masdevallia-house, and where atmospheric moisture is abundant. In regard to repotted plants, water at the root must be given with great care. Established plants may be benefited by an occasional application of weak farmyard manure-water. C. Mastersii does not like such heavy soil, and a larger proportion of sphagnum-moss will be necessary. The hybrids from C. eburneum and C. Lowianum and C. giganteum, providing the growths have not made too much headway, may be treated similarly to C. eburneum, but they require rather more root-room. A lighter position likewise should be found for them.

Eulophiella Elisabethæ, so far as my experience goes, thrives best at the warmest end of the Phalænopsis-house, where, during the summer months, the heat is great, and moisture abundant. The plants are now producing long, creeping rhizomes, from the ends of which the growths will develop. Before roots are emerged from these rhizomes the plants may be top-dressed or repotted. Their rambling habit necessitates the use of rather large receptacles, but sometimes the rhizomes may be induced to remain inside the boundary by carefully pegging them down on the soil. Provide pans with a large quantity of drainage material, and this should be surfaced with about an inch or so of compost only, which may consist of fibrous loam and peat in equal parts, and a similar amount of sphagnum-moss, adding a good proportion of finely-broken crocks as the work proceeds. Atmospheric moisture being plentiful, little water at the root is necessary until the plants are in very active growth, when the soil must not be permitted to remain dry even for a day. The leaves may be sprayed several times a day during bright weather, and occasionally they should be sponged.

Phaius grandifolius and others.—This useful winter-flowering plant, also P. Wallichi, and the various named varieties, should be grown in a warm intermediate temperature, shaded from direct sunshine, and if possible be stood on some moisture-holding material. Being strong and vigorous-rooting plants, they require ample root space, and a fairly strong compost, viz., equal parts of peat and loam, which should not be broken finely. After placing a few large crocks at the bottom of the pots, a fair proportion should be mixed with the soil. The roots are very brittle, and usually rot where bruised or broken. For a considerable period of time after repotting, only afford sufficient water to prevent the compost becoming dust-dry. Plants not disturbed will require a moderate supply of water, and occasionally weak manure-water. Green-fly and mealy-bug attack the young leaves, which must be carefully sponged should bugs appear. The aphis may be destroyed by fumigating the plants frequently.

Hybrid Phaius, such as P. × Cooksoni, P. × Normani, P. × Owenianus, P. × Marthiæ, &c., require a higher temperature than those of the P. grandifolius section, but otherwise the treatment given them should be very similar. The soil, however, needs to be mounded from the rims of the pots.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

Cucumbers.—If no second sowing be made, and the early-raised plants must be kept in vigour throughout the season, frequent attention should be given both to the roots and the plants themselves. There is nothing that so well sustains growth as new, or at any rate, a fresh soil. A layer of turfy loam not too finely broken, put on as often as the roots come through the surface of the bed, will maintain healthy and fruitful growth, providing other conditions are favourable. Abundance of water will be needed on hot sunny days, with a syringing of the leaves not less than twice a day, and keeping all bare surfaces damp. With these conditions maintained, red-spider and aphides will not give much trouble. A regular supply of Cucumbers, even with vigorous plants, cannot be maintained without repeatedly stopping the lateral shoots, which should be carried out, at the least, once each week, when exhausted and damaged leaves or weak shoots may also be removed.

Frame Cucumbers.—Frames and brick pits now being cleared of their temporary occupants should be got in readiness for planting with Cucumber plants. It is not necessary to provide dung-beds specially for summer frame Cucumbers, if these have been provided for the other plants, as there will be sufficient warmth remaining in the materials to start and carry on the growth of Cucumber plants without any additions. By utilising solar-heat by closing the lights early in the afternoon, affording no shade, and by modifying the watering and syringing in accordance with the state of the weather, Cucumbers will grow and fruit well during the summer. The same rules apply in all particulars to frame-grown plants as to those in houses. Always use water warmed in the sun or by mixing it with hot water for syringing the leaves or moistening the soil. The Cucumber roots readily from cuttings placed in the Cucumber-bed without bell-glasses over them, and it needs only the tops to be taken off healthy plants and dibbled into the soil for them to become rooted in a few days, if the bine on the roof affords a heavy shade, and water be afforded copiously. Plants raised from cuttings fruit sooner than seedlings, and the cuttings when rooted may be lifted with a ball of roots and soil attached, and planted at once in a house or frame. All the same, seedlings are generally preferred, because they are more vigourous, endure longer in bearing, and carry more fruits. The fruits of frame-grown plants are apt to be discoloured when allowed to lie on the soil of the bed, and are then not nearly so presentable as are fruits which depend from the roof-trellis of a house. Cucumber glasses or a layer of small Pea-sticks spread over the bed, will obviate this. Do not allow the fruits to remain on the plants till they become of a large size, or permit ill-shapen fruits to remain.

THE KITCHEN GARDEN.

By H. Markham, Gardener at Wrotham Park, Barnet.

Thinning Young Vegetables.—Onions, Carrots, Parsnips, &c., will need immediate attention in respect to thinning, weeding, and hoeing. Onions should not be severely thinned except they be required for exhibition, bulbs of medium size being the more useful and better keepers. Draw the young plants with care so as not to disturb those left to mature. Should the plants have come up somewhat irregular in the rows, some of those pulled out should be dibbled in the vacant spaces. Onions may be transplanted very successfully in showery weather. When the thinning has been completed and an attack from maggot is feared, afford the whole of the beds a dressing with fresh soot. Carrots and Parsnips require to be thinned twice, first when the plants are not more than 1 inch high, when all clusters should be reduced; and later, when the young plants should be given individually a space of 3 to 6 inches, or even 8 inches in the case of Parsnips. Do not omit to sow at intervals small beds of Carrots of the Short-horn type. Remove the largest roots of Carrots or Turnips growing in frames, and if the frames are required for another purpose, the whole of the crop may be lifted, and those roots of a useful size laid in thickly on a north border, in which position they will keep for some time longer.

Leeks.—Lift without delay any Leeks still unused, and bury the stems to a good depth to preserve them. Prepare trenches for the coming maincrop, and if large Leeks are required, make the trenches similar to those intended for Celery, with the exception that more and richer manure should be dug into the bottoms of the trenches. For ordinary purposes, a good strip of land, deeply dug and well manured, will answer well. The drills should be drawn out rather deeply at 14 inches apart. Put the plants 8 inches apart in the rows. If the land has been heavily cropped, afford it a good quantity of manure, and when the drills have been drawn, soak them with liquid-manure, &c., delaying the planting until the following day.

Lettuce.—Sow at intervals in rows where the plants are intended to heart some of the most approved Cos varieties, but do not sow the seed thickly, nor fail to thin out early. It is a good practice to leave every alternate drill to be filled up with young plants as each row is thinned; those transplanted making a good succession.

Jerusalem Artichokes should be earthed-up before the tops become too high for this work to be done conveniently.

The Garden Walks.—Keep the walks free from weeds, and let them be well rolled. Box-edgings may now be clipped and trimmed.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Episcia (*Cyrtodeira*) *metallica.*—This very pretty and free-flowering Gesneraceous plant may be readily propagated by means of the freely-produced side-shoots or runners. Take these off with an inch or so of stem when they have made three or four leaves, and insert them in small pots filled with sandy-soil, or dibble them into the cocoa-fibre of the propagating-frame. Grow them on in a brisk heat, and eventually pot each into 5-inch or 6-inch pots. A suitable soil would consist of two parts loam, one part leaf-soil or peat, and a liberal addition of silver-sand. The dwarf habit and ornamental foliage of this plant render it very useful for furnishing the edges of the stages in the stove. The brilliant scarlet flowers only last a few days, but a succession of them is produced for a considerable time.

Chrysanthemums.—In some cases plants in 6-inch pots have made so many roots that they need to be transferred to their flowering-pots at once. The final potting of later plants should be completed during the first week in June, except that of a few backward plants. Pots 9 inches in diameter are sufficiently large, and the stronger-growing varieties should be given the larger size. Thorough drainage is essential, and the compost may consist of three parts good turfy loam, half a part each of flaky leaf-soil, stable-manure, and well burnt garden refuse, together with sufficient coarse sand to keep the whole porous. To each wheelbarrow-load of this compost a 4-inch potful of bone-meal may be added. If the loam be stiff, the compost should only be made moderately firm, but if light the plants can scarcely be potted too firmly. The plants when potted may be stood together for a few days in a sheltered position, and if they are syringed two or three times a day during fine weather, it will assist them to overcome the check caused by the disturbance of the roots. Secure the stems to stakes, and when established, remove them to their summer quarters.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

The Destruction of Insects.—During spells of cold weather and easterly winds, greenfly increases on Peach and Nectarine trees very rapidly, and curled leaves and shoots are the result. A thorough syringing with an infusion of Quassia chips should be given the trees each week for some time. Apply the liquid at a temperature of about 90°. Forcible applications of cold water at intervals, when the weather is warm, will also assist in keeping the trees clean. The cold winds of the past few weeks have also apparently brought on an attack of blister in Peach and Nectarine trees. All such leaves should be removed and burned, and those shoots badly affected pinched back. Should mildew appear on the trees, syringe with Gishurst Compound, at a strength of 2 oz. to the gallon of rain-water, or failing this, a mixture of water, soft soap and sulphur should be applied. The caterpillars which infest the Cherry, Pear and Plum, and wall trees generally should be looked for two or three times weekly. When disbudding or pinching back the shoots of these trees, infested bits should not be thrown on the borders, but into some receptacle until they can be burned.

Removing surplus suckers from Raspberries.—Raspberry plants are now growing fast, and the young canes should be thinned; and unless required for future transplanting they may be thinned down to three or four growths to each stool, removing the weakest ones by pulling them out. When, however, stock is required for forming new plantations, the suckers more distant from the stool should be allowed to remain for this purpose. Autumn fruiting varieties should be afforded sufficient room to allow of the canes being tied thinly to the wires. Stir the surface soil, and if the ground be of a light nature, apply a mulch of half-rotten manure, following this by a thorough soaking with weak liquid-manure.

The earliest Strawberry-bed is usually placed on a south border, and it should always consist of young plants, for these produce ripe fruits sooner than two-year-old plants. In such a plantation the most forward blossoms will now be well set, and a few of the later ones may be thinned out. This will tend to increase the size of the fruits and aid development. Beds treated as described have usually produced ripe fruits early in June, sometimes even in May, but according to present appearances, ripening will be at least a fortnight late this year.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Bedding-Out.—The hardier kinds of bedding-plants, viz., Calceolarias, Gazanias, Verbenas, &c., may now be safely planted. The Pelargoniums in its several sections and varieties, Lobelias, Erinus, and Petunias will be better if left unplanted till a week later. Antennaria and Cerastium tomentosum form neat edgings to some kinds of beds, and if small pieces are planted in lines three inches apart, they soon take root and grow. Echeveria secunda glauca is another bold edging plant, requiring to be tilted when planted, so that the water does not remain in the heart of the plant. Continue to gradually harden off the stock of tender plants, such as Heliotrope, Fuchsia, Coleus, Iresine, and the various subtropical plants.

Window-boxes.—These should now be filled with soil; using for preference rough pieces of turf for drainage. See that the boxes are secured from wind, and made perfectly level. The deeper the boxes, so much the better for the plants. Pelargonium peltatum (Ivy-leaved), in all its varieties is an excellent plant for filling these, especially the pink variety, Madame Crousse. This, if planted near the edge of the box droops gracefully over the sides, and continues to flower the whole of the summer. The yellow and white-flowered Marguerites (Chrysanthemum frutescens) also do well in boxes. In windows fully exposed to the sun the dwarf Nasturtiums are excellent, the seeds being sown now, at 1 inch deep in the soil. But window-boxes on the north side of a house or which are much shaded should have Ferns and foliage, not flowering plants, placed in them.

Climbers.—Thin out the growths so as to avert a crowded state of the branches and shoots, securing loosely sufficient of them to cover the space. A few shoots well matured always give the finest results in respect of blossoms. The Clematis require almost daily attention, as growth is very rapid, and the plants, if neglected, soon become tangled masses, impossible to be dealt with. Climbing Roses that have been tied in closely to resist the wind, should now be fastened more loosely, in order to allow the young growth to spread, especially is this necessary with Turner's Crimson Rambler. Magnolia grandiflora should have the long bare branches cut out, and younger shoots tied in their place, leaving sufficient space for the coming season's growth. It is not a good plan to tie one shoot upon another, as is often done, the older heavy leaves shading the undergrowth and causing it to die back; the shoots, too, being so far from the wall do not ripen properly, and it is one of the causes of Magnolias not flowering well.

Bulbs.—Most of the Narcissus and other bulbs will have passed out of flower, and the present is a suitable time for marking such as need to be taken up when the foliage is ripe, and to be divided and replanted in a fresh place. This may be necessary in from three to five years. Do not cut off any green leaves, as to do so impoverishes the bulbs, and is a cause of failure.

Pæonies.—A copious application of manure-water to the tree and herbaceous kinds will strengthen the growths and increase the size of the blossoms. Let the stems be supported, or the rain will break down the flower-heads, or cause them to bend to the earth; moreover, a flower fully exposing its petals to the sun comes of a finer colour than one that hides them, as does a pendent bloom.

THE APIARY.

By Expert.

Swarming.—Where bees are doing well and increasing rapidly, their over-zealous owners frequently become impatient in their anxiety for swarms, artificial or natural. To such we say, do as much as you like to help your bees forward, but do nothing which will throw them back, and unless the weather becomes very settled and warm, do not be in a hurry with artificial swarming. In any case, the end of the month will be soon enough this year to think of breaking in upon the prosperity of stocks by dividing. We have long maintained that the very best time for either a natural or an artificial swarm is the beginning of June, because it gives ten days or so in which, by the aid of foundation and feeding, the hive may be well furnished with combs, and a good portion of these combs occupied with eggs and brood before the Clover is in full bloom. Then is the time to see a swarm work in earnest, and to note how rapidly it will shoot ahead of one which has been hived earlier, and has lost heart through lack of food.

Artificial Swarms.—Under certain circumstances, artificial swarming is simple enough. Given fine warm weather, and two strong stocks of bees, it only requires that the queen be lifted out of hive No. 1 with the frame of comb on which she happens to be found, and placed in the centre of a new hive, the frames of which should be fitted with foundation; or, preferably, frames of comb and foundation alternately. The new hive is then set on the stand previously occupied by No. 1, and No. 2 is moved some distance away to a new stand, while No. 1 takes its place on No. 2 stand. Thus the new hive gets the queen and all the flying bees of No. 1 (this, of course, constitutes the swarm), while the adult bees of No. 2 take possession of the combs and brood of the former, raising for themselves a new queen from the brood left in the hive. If this operation is performed in the middle of a fine day it will very rarely fail. This is the simplest and safest method of forming an artificial swarm. Should natural swarms have come off before the issue of our next number, they must be fed daily during the bad weather. A few wet or cold days immediately after hiving greatly check the progress of new swarms, and it is of the utmost importance to keep them going by feeding as long as adverse weather lasts.

Special Work.—All that can be done must be done in nursing any stocks that are weak in numbers, but making rapid progress. Keep the slow feeder constantly going if food is scarce, or uncap sealed stores once or twice a week if there is plenty on hand. Suitable spring food may be prepared by pouring hot water (3 pints) on 5 pounds of refined cane-sugar, stirring till the sugar is dissolved, and giving the food whilst it is just warm. Keep entrances narrowed till bees become busy, and they want room for coming and going. See that quilts fit closely down, and that no escapes at the top of the hives. When the first overhaul of hives is made, let it be really thorough, and make a note of their condition; this note to be tacked inside the roof, or placed where it will be easy to refer to when needed. On this state what progress is being made in brood-rearing, and what feeding, &c., is required, and do not disturb the brood-nest again, so long as progress is maintained, until the weather gets quite warm and genial. Except in early counties, it will be time enough to think of surplus-room when our next number is issued. Some stocks which have wintered on a few frames will require additional combs early in the month; no disturbance of the brood, however, is needed in giving these. When there are bees on all the combs, add a frame on each side once a week, till the full complement is reached. Should the weather be favourable, and a colony is strong, and making very rapid progress, usually give the full number of combs at one operation, to save further trouble.

"THE FLORA OF KENT."—We are pleased to be able to announce the publication of a volume devoted to this subject by F. J. Hanbury, Esq., and the Rev. E. S. Marshall. The book has been long expected; and as it refers to one of our most interesting counties, and is the work of two of our most distinguished British botanists, it may be anticipated that it will receive a cordial reception at the hands of botanists. We shall have occasion to refer to it at greater length on another occasion. In the meanwhile, we may state that the book is to be had of Mr. F. J. Hanbury, 37, Lombard Street, London, E.C.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, May 31 { Annual Exhibition of the Royal Horticultural Society, in the Gardens of the Inner Temple, London (3 days).
THURSDAY, June 1—Linnean Society Meet.

SALES.

TUESDAY, May 30 { Special Sale of Orchids in Flower and Bud, at Protheroe & Morris' Rooms.
FRIDAY, June 2 { Imported and Established Orchids at Protheroe & Morris' Rooms.

Remarks.—The weather during the week has been very unsettled and dull, with a thunderstorm on the 16th. Rain fell on five days, the heaviest quantity being on the 14th, which was the greatest fall for any one day this year.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—58·1°.

Actual Temperatures:—

London.—*May* 24 (12 p.m.): Max. 63°; Min. 52°.

Provinces.—*May* 24 (6 p.m.): Max. 52°, South Coast; Min. 42°, Sumburgh Head.

Weather showery.

Seaside Planting.

Seaside planting offers peculiar difficulties, and the planter has often to make use of subjects which he knows will answer his purpose, rather than others of a more ornamental character.

The beach-gardens at Folkestone offer an illustration. They are only just beyond high-water mark. In stormy weather they are drenched with spray, and exposed to the full fury of the south-westerly gales. Moreover, they are placed upon an under-cliff of lower greensand rock, alternating with bands of blue-clay. Landslips consequently are of frequent occurrence. To obviate these as far as possible, great use is made of the so-called Tea-tree, Lycium barbarum. It is deciduous, and forms a tangled thicket of shoots, which in winter-time is not attractive to the eye, but which serves as a wind break. Its chief value, however, consists in the freedom with which it produces underground suckers and runners. These are so numerous and so intricate that they hold up the loose, treacherous bank in a manner that no other plant known to us could surpass. Just now, these suckers are clothed with foliage of a rich, clear green, which may perhaps have suggested the popular name. Behind the Tea-tree hedge, or mixed with it, the common Elder is planted. It is not very ornamental, being distorted and blown out of shape, but it forms a good protection; the young shoots get killed by the salt-blast, but they remain as a thicket of brush-wood, which serves to temper the wind, whilst in spring a forest of new shoots is formed to replace the older ones, and in their turn to share the same fate. Indeed, during the interval that has elapsed between the writing of this note and its appearance in type, a severe gale has played havoc with the newly-formed shoots on the exposed side of the shrubs. Some of the Willows are used for like purposes as the Elder and the Lycium. The Tamarisk, not yet in leaf, is very elegant in its finely-divided branching, and in the ruddy colour of its bark. It was introduced to the Kentish coast by the late Mr. Masters, of Canterbury, and is one of the very best of shrubs for seaside planting at the verge of the sea. Gorse, with its brilliant flowers, is sparingly employed, but might be much more freely used. Maples, Sycamores, and Elms form thickets in which the nightingale and other birds find shelter.

Of evergreen trees, the Evergreen Oak is one of the hardiest; its leaves, indeed, get browned on the exposed side of the tree, but they are soon replaced by young foliage in spring. Of Conifers, Cupressus macrocarpa does not do so well as in the Isle of Wight and other localities. The Pinaster soon gets shabby, but the Black Austrian Pine forms admirable shelter plantations, just now very striking with their young buds, projecting upwards like so many candelabra. The only objection that can be raised is as to the density of the shade, which prevents any undergrowth. The vegetation of the Folkestone sandstone cliffs is naturally of the most interesting character to the botanist, but it is destroyed wherever these Pines grow; hence, while grateful for occasional plantations of these trees, we hope the authorities will extend them with discretion, and take care to leave wide areas in their natural condition.

Reverting to shrubs planted by the gardener, we may mention the Euonymus as specially suitable for seaside-work. Its rich green, or in many cases brilliant golden foliage, render it very attractive. Escallonia macrantha is also a shrub which may be highly commended, as it is rarely hurt by frost, even on the Kentish coast, and its glossy foliage and pink flowers are both attractive. The broad-leaved Privet forms excellent hedges. Lavatera arborea, the Tree Mallow, is wild, or at any rate "naturalised," hereabouts, and its appearance is sufficiently striking to attract attention. Though it is of little use for shelter, it will grow on the very edge of the sea, and is now common all along the coast as far west as Hythe. It is unnecessary to go into further detail with regard to shrubs and trees, for within the shelter of the subjects we have mentioned almost all our hardy shrubs will grow, and flowers attain a brilliancy unknown save by the sea.

We should like to add an emphatic warning to our Folkestone friends, not to encroach any more on the cliff beneath the Leas for additional paths or any other purpose whatever. Its great charm is in its wildness, and in the shelter it affords to wild birds and plants. There are certain thickets of deciduous trees which now form a paradise for birds, and to disturb them would be sacrilege. It would be far better to do away with some of the paths than to create new ones: with a little contrivance, the public convenience could be equally well satisfied by amalgamating some of the present paths, and by doing away with others. On this bank grows the wild Sea Pink (Armeria), Iris fœtidissima, Hippophae rhamnoides, a wealth of Trefoils, and Medicagos, dear to the botanist, and a host of other interesting plants. Just now portions of the cliff present a very striking appearance, from the noble masses of Smyrnium Olusatrum in full bloom. Lepidium Draba forms sheets of white flowers, this is a plant introduced to Folkestone within our own recollection, and it is now competing for supremacy vigorously with Brassica nigra, Smyrnium, Lucerne, and other plants. Indeed, the study of this bank, whether from month to month during the season, or from year to year over a series of years, is most interesting and instructive. As a good many garden plants, like the Scabious, the Marigolds, and the Borage, find their way here from time to time, the young botanist must exercise his discretion before pronouncing upon the "wildness" of the plants he finds. Whilst there are certain bare places on the cliff which might advantageously be planted with Gorse or Sea Buckthorn, Clematis, or other native plant, we most earnestly plead for the protection, and, if possible, extension of the wilder portions of the Folkestone undercliff.

As for the formal gardens on the Leas above the sea, they are too well kept. The authorities seem to want reminding that shrubs and trees, left to themselves, or slightly regulated, have each their own beauty of form, and do not require to be shorn like the grass lawns or hedges. It may be necessary to restrict the too rampant growth of Euonymus and Evergreen Oaks, and other trees and shrubs, but it is not necessary to cut them all without discrimination into the shape of dumplings and dish-covers.

Dianthera illustris. — An Acanthaceous plant (fig. 122) was exhibited under this name by Messrs. F. Sander & Co., St. Albans, at a meeting of the Royal Horticultural Society, on April 18. The foliage is entire, acuminate, opposite, and of a dark green colour. The showy character of the plant is chiefly due to the red or crimson bracts of the inflorescence, which is produced at the extremity of the growth, as in Jacobinia. The tubular corolla is light purple. The general appearance of the plant is also suggestive of a Jacobinia.

Linnean Society.—On the occasion of the evening meeting to be held on Thursday, June 1, 1899, at 8 p.m., the following papers will be read:—I. "On the High-level Plants of the Andes, as illustrated by the Collections of Sir W. Martin Conway, Mr. Edward Whymper, and Others," by Mr. W. Botting Hemsley, F.R.S., &c. II. "On some Australasian Collembola," by Sir John Lubbock, Bart., F.R.S., &c.

—— The anniversary meeting of the Society was held on May 24, when Dr. Günther read an address on the "Collection of Fishes accumulated by Linnæus," and now in the custody of the Society. A special feature of the meeting was the

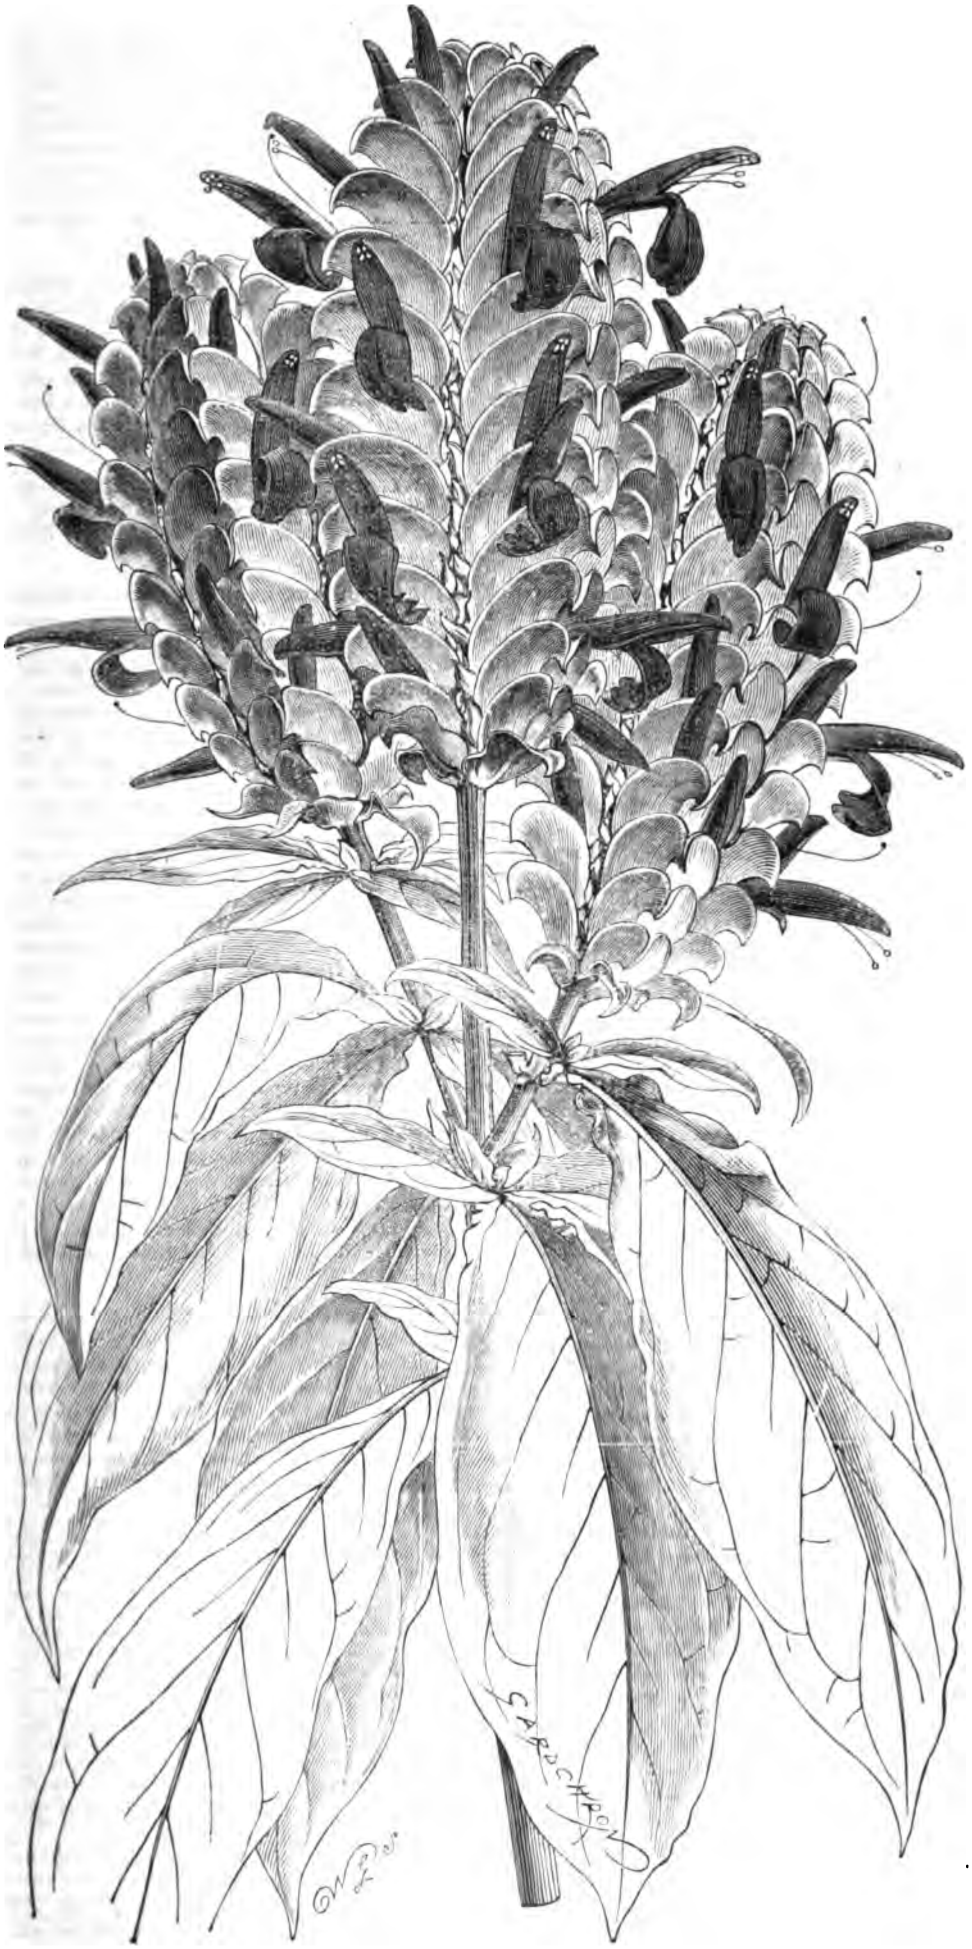

Fig. 122.—DIANTHERA ILLUSTRIS.
Colour of the flowers light purple, and that of the bracts crimson. (See p. 338.)

presentation to Mr. J. G. Baker of the Linnean Medal, an honour which is awarded each year to a distinguished naturalist, a botanist, or a zoologist, being chosen in alternate years. Dr. Günther, in presenting the medal, alluded to the very numerous and important contributions to botanical science made by Mr. Baker during his career at Kew, as well as previously—contributions, the value of which is highly appreciated abroad as well as at home. He trusted that in the leisure Mr. Baker has now attained, further work may still be expected from him. Mr. Baker, in acknowledging the honour conferred on him, alluded to the encouragement afforded by the Society to naturalists, who, but for the Society's aid, could not publish the results of their labours without great expense. There was a general feeling that the medal was most worthily awarded, and Mr. Baker, who was accompanied by Mrs. Baker and their son and daughter, received the warmest congratulations on the occasion, congratulations in which the readers of the *Gardeners' Chronicle* who have derived such advantages from his communications to our pages will cordially join.

Queen's Trees.—We have to add another Oak to the list of trees known to have been planted by Her Majesty, printed in our issue for June 19, 1897. On the occasion of the eightieth anniversary of her birthday, the Queen planted an Oak near one of the lawns at Windsor. *Floreat!*

The Temple Show of the Royal Horticultural Society is an event annually anticipated with the greatest enthusiasm by gardeners generally. Its success as an exhibition has been extraordinary on every occasion. In respect to the show that will be opened on Wednesday next, the following interesting particulars have been supplied us by the Society's secretary:—"For the twelfth year in succession the Royal Horticultural Society will hold its great annual flower show in the Inner Temple Gardens (by the kind permission of the Treasurer and Benchers) on May 31, and June 1 and 2. Every year there is an increased desire on the part of cultivators to exhibit, and the officials of the Society have a very anxious task in their endeavour to do justice to those growers who regularly support the fortnightly shows of the Society held at the Drill Hall, and yet at the same time to encourage others to come forward. The space is absolutely limited, by order of the Temple authorities; no more or larger tents may be erected. Hence, every new exhibitor whose entry is accepted necessitates a curtailment of the space allotted to previous supporters. A catalogue of the show is given gratis to every visitor, and this will contain a notice of new and rare plants entered on or before May 23; it will also contain a programme of the music to be performed each day by the band of Her Majesty's Royal Horse Guards (Blues). The judges will meet at the secretary's tent at 10.30 a.m., on May 31, at which hour punctually the tents will be cleared of all exhibitors and their assistants. The Fruit, Floral, and Orchid Committees will assemble at the secretary's tent at 11 a.m., and the show will be opened at 12.30. All plants for Certificate must be entered on or before Friday, May 26. Address the Secretary, Royal Horticultural Society, 117, Victoria Street, S.W. They cannot be entered under any circumstances on the day of the show."

Gardeners' Royal Benevolent Institution.—A largely-attended meeting was held on May 16, at Reading, for the purpose of forming a local branch of the Institution. Mr. Arthur Sutton has taken a prominent part in the formation of this branch, which has also the warm sympathy of Mr. Martin Hope Sutton. Mr. Harry Veitch, Mr. O. Thomas, and a large number of gardeners from the neighbourhood took part in the proceedings. Mr. O. Thomas pointed out that out of some 25,000 gardeners there were only about 600 who subscribed to this Institution, founded for their special benefit, and hoped that the formation of this local branch would greatly add to the numbers of subscribing gardeners. Mr. Keyser was appointed president of the branch, Mr. A. W. Sutton was elected treasurer, Mr. H. G. Cox was appointed hon. secretary, and the following committee was elected:—Messrs. Neve, Ashby, Combes, Trollope, McHattie, Stanton, Pope, Galt, Kitt, Thatcher, Heath, Wise, Maxim, Lees, Fry, Exler, Pound, Smith, Tegg, and Bryden.

HORTICULTURAL CLUB.—The usual monthly dinner and conversazione took place on Tuesday at the rooms of the club, Hotel Windsor, there was a good attendance, both of members and their friends. The chair was occupied by the Rev. W. WILKS, in the unavoidable absence of Sir J. D. T. Llewelyn, Bart.; there were present beside, Sir John Furley, Messrs. J. H. Tritton, C. E. Shea, R. Gofton Salmond, George Monro, Peter Kay, H. A. A. D'Ombrain, H. Somers Rivers, C. Mason, Philip Crowley, Dr. Maxwell T. Masters, and others. A very interesting paper was read by Mr. Gofton Salmond, on the "Preserving of Vegetables by Evaporation," and a number of specimens of vegetables so prepared were exhibited. An interesting discussion followed, in which most of those present took part, and the feeling among all was that the process would be invaluable for the army and navy, and for all expeditions where the obtaining of fresh vegetables would be a matter of difficulty.

THE LINDLEY LIBRARY. — Visitors to the Lindley Library in the Council-room of the Royal Horticultural Society will observe with pleasure that the books are now all enclosed within glass cases, which add materially to the appearance of the apartment, while they secure the books from some, at least, of the defilements of the London atmosphere. The cases have been provided by the munificence of the Council of the Royal Horticultural Society.

THE SURVEYORS' INSTITUTION.—The annual general meeting of the Institution, to receive the report of the council, and the announcement of the result of the election of officers for the ensuing year, will be held on Monday, May 29, 1899, at 3 o'clock, at the new building, 12, Great George Street, Westminster. The prizes awarded to successful candidates, in connection with the recent preliminary and professional examinations, will be presented by the PRESIDENT at the annual general meeting. The Institution is now removed to the new building, 12, Great George Street, Westminster, to which all communications should be addressed.

THE ACADEMY OF SCIENCES.—M. ED. PRILLIEUX has been elected a member of the Academy in the place of M. NAUDIN. M. PRILLIEUX is well known in this country for his researches in vegetable pathology.

FATAL ACCIDENTS FROM A FALLING ELM.—At Powis Park, Welshpool, the seat of Earl POWIS, during a strong southerly gale, a large Elm standing near the approach drive was overturned, and falling on a group of children, killed one of them on the spot, severely injured two others, all of one family, one other child belonging to another family being injured in the spine. Miraculous escapes occurred to others from the falling branches. The tree was apparently sound, although at the root it was decayed.

GARDENING FOR WOMEN. — At the Exeter High School for Girls recently, Miss SIEVEKING, hon. secretary of the Women's Branch of the Horticultural College, Swanley, Kent, gave a lecture on "Gardening as an Occupation for Women." She explained that the female side of the college was opened in consequence of a large number of applications received from women who desired to study the art or science of horticulture. There are very few of the operations connected with horticulture which were beyond the strength of an average woman, and it had also been proved that gardening was a suitable employment for women. Although they could not expect to obtain riches from this work, they could at any rate make a comfortable livelihood. The open-air life was healthy, and the girls improved under it to an extraordinary extent. There were always good positions available for the students after they left the college, and there were many who were at present employed as gardeners in various parts of the kingdom. Miss SIEVEKING, in an interesting way, explained the routine of the college, and the method of work adopted, and, in conclusion, expressed the opinion that any occupation which drew girls away from the bustle of large cities and gave them quiet and healthy employment, was to be commended. Mr. H. TOLSON asked what girls did best at the college, and Miss SIEVKING replied that those who had a good all-round education, because they were able to spend more time in the gardens.

THE ROYAL GARDENS, KEW, have appeared very charming during the Whitsuntide holidays, and, as usual, the number of visitors has been large. In the grounds some of the early-flowering shrubs are in full bloom, including the glorious Lilacs and hardy Azaleas; the pink and white-flowered Thorns being, as yet, not fully at their best. But the late-flowering bulbs upon the grass, the last of the Tulips to flower in the beds, including an admirable display of the Parrot varieties; also the great breadths of Blue Bells under the trees, and the plants in bloom in the alpine garden, are all features that offered much gratification to visitors who had eyes to see them. In the Water-Lily-house the beautiful hybrid and other Nymphæas bore plenty of flower-buds, but unexpanded. The Victoria Regia, in the house which this plant has made an extremely popular one to the public, has yet put forth only a few early leaves, but with the plant of the Double Cocoanut at the margin of the tank, it appeared to excite much interest. The Orchid-houses contained a fairly good display of bloom of Cattleyas, Lælias, many variations of the Slipper Orchid, Odontoglossums, and other species. The Orchid-houses since being rebuilt have a much better appearance. The Stove, Begonia-house, and the new Nepenthes-house, were all as interesting as usual, but visitors were at a loss to explain a smell prevalent in this part of the T range, which was due to one of the more modest-looking of the Amorphophallus. The Greenhouse (No. 4) presented a gay picture, and contained a wealth of flowers. Amongst the species of plants contributing to the general effect were Schizanthus pinnatus, Collinsia bicolor, Azaleas, hybrid Cinerarias, some of which were plunged or planted in the beds, and were charming decorative plants, measuring in instances 3 feet to 4 feet across; Achimenes, Celsia cretica, Nemesia strumosa, a small-flowered annual, very suitable for cultivation in pots, flowers of varying shades of yellow to deep orange colour; Petunias, Ixias, Begonias, Gloxinias, Fuchsias, Lonicera sempervirens minor, Hydrangea paniculata, Viburnum tomentosum plicatum, Boronias, Daphne Cneorum, Wistaria chinensis, and W. c. alba, a nice batch of herbaceous Calceolarias, Scutellaria Mociniana, Lilium candidum, &c. The disposition of these plants in batches in place of the "miscellaneous groups more frequently seen in gardens," is a pleasing one. The Temperate-house, which has awaited completion so long, but is now perfect, offered many interesting features, not the least being some profusely-flowered plants of the fragrant Rhododendrons.

TREASURE IN A LONDON GARDEN.—One of the gardeners employed in the Lincoln's Inn Fields found buried there, in October last, ninety-four rings, that were stolen from a jeweller's shop in May last year. Knowles, the gardener, took the rings to the police-court, and was on Tuesday last given the not too liberal reward of £1, which was awarded by the owner of the rings on the suggestion of the magistrate.

RHUBARB LEAVES AS A VEGETABLE.—In the *Information Gazette*, Oxford, it is said that Rhubarb leaves, "if deprived of their larger ribs and cooked like Spinach, make a most delicious dish, with no suggestion of the flavour of Rhubarb tart." Have any of our readers given them a trial. If it be possible to make these leaves into a "most delicious dish," we may see our way to the utilisation of another waste product.

TOMATO WINTER BEAUTY.—We understand that the entire stock of Mr. MORTIMER's new Tomato, which was exhibited at the Royal Horticultural Society's meetings at the Drill Hall on April 18 and May 2, and which received the Society's Award of Merit on the former date, will be distributed next season by Messrs. SUTTON & SONS, Reading.

WELBECK ABBEY STRUCK BY LIGHTNING.—It is reported that on Tuesday last the turret clock and other portions of Welbeck Abbey, Worksop, were damaged by lightning.

AGRICULTURE AND GARDENING IN ALASKA.—The projected agricultural experiment station in Alaska is, as we learn from the *Times*, May 15, an accomplished fact, its organisation having been completed under the auspices of the United States Department of Agriculture. The main station is at Sitka, which lies in the same latitude as the north of Scotland, but with a far more rigorous climate. Land near to Sitka is also to be cleared for the erection of log silos, wherein to silo the native grass, which is abundant and good, but not readily made into hay, on account of the frequent rain and excessive humidity. The new station will be supported at the expense of the United States Government, and not subject to the provisions of the well-known Hatch Act. It has been demonstrated that Oats and Barley will not only make excellent growth, but will ripen their grain in south-east Alaska. This point has not been ascertained as regards Wheat and Rye, but experiments on autumn-sown grain are in progress. Clovers and Flax grow vigorously; and among vegetables, Asparagus, Beetroot, Carrots, Kale, Cress, Lettuce, Onions, Parsnips, Peas, Potatos, Radishes, Salsafy, Rhubarb, and Windsor Beans, did well on old ground. Very few succeed on new ground, but they languish and die. It is raw, sour, water-logged, and contains much decayed wood, requiring aërating, and liming to make it suitable for most kinds of cultivated plants.

INFORMATION WANTED.—With reference to the caution to advertisers which we published a short time ago, warning them against a man who replied to their advertisements, and offered situations for a fee, or to supply goods, but required cash in advance, we shall be glad if any of our advertisers, who have been duped, will communicate with the PUBLISHER at once.

PUBLICATIONS RECEIVED.—*Eleventh Annual Report of Agricultural Experiment Station, University of Illinois, for the Year ending June 30, 1898.*—*Bulletin*, No. 54: Spraying Apple-trees, with special reference to Apple-scab Fungus.—*Meehans' Monthly* for May, 1899.—*Japanese Botanical Magazine* for March, 1899, No. 145, containing Notes on Eastern Asiatic Plants, Marine Algæ of Japan, Rare Japanese Plants, Morphology of the Pollen-cells, and the Spermatozoid of Ginkgo; Hybrid Orchids, the Penetration of Chalk and Bones by Fungus, &c.—*Annual Report on the Royal Botanic Gardens, Trinidad*, for 1898, by J. H. Hart, F.L.S.—*Annalen des K. K. Natur-historischen Hofmuseums, Vienna*, vol. xii., Nos. 3 and 4; vol. xiii., No. 1.—*Bulletin of the Botanical Department, Jamaica*, by Wm. Fawcett, B.Sc., F.L.S.—*American Journal of Science*, two extracted papers, viz., "Plants of the Crowfoot Family," by M. L. Fernald; and "Illustrated Flora of the Northern U.S.A. and Canada," by Nathaniel Lord Britton, Ph.D., Hon. Addison Brown.—*Descriptive Notes on Fibres*, prepared for the Greater Britain and Paris Exhibition from Plants, Indigenous and Exotic, Cultivated in the Botanical Gardens, Melbourne, by Wm. Robert Guilfoyle, Director.—*The Alkali Soils of the Yellowstone Valley* (U.S. Department of Agriculture), No. 14.—The *Orchid Review* for May, 1899, contains some interesting articles on "Feeding Orchids," "Freaks among Orchids," "On Hybridising Orchids," "Affording Water to Odontoglossums," &c.

NOTICES OF BOOKS.

EDIBLE AND POISONOUS FUNGI OF JAPAN.

A GIFT has recently been made to the British Museum (Natural History) by Mr. K. Minataka of two illustrated volumes descriptive of the larger fungi of Japan, by Mr. Sakamoto. Translations in English of many of the descriptions have been appended by Mr. K. Minataka, but the introduction is not translated. There are no scientific names, so that it is not easy to say for certain what species some of the drawings represent. The illustrations are in outline; these are both excellent and artistic. Unfortunately, the artist has given no sections, and the colour of the spores is not given. Reference is once made to the *Handbook* of Dr. M. C. Cooke. From a strictly botanical point of view, the volumes are therefore defective; but the illustrations are so highly natural, and so remarkably well done, that, taken with the descriptions, a close approximation to the true scientific names is often possible. In some instances the name can be given with certainty.

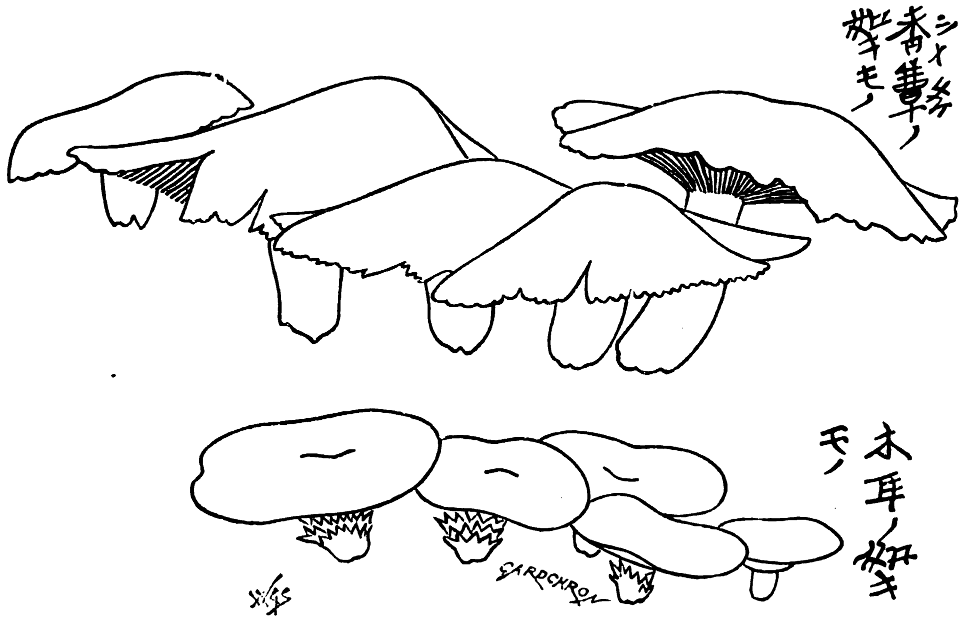

FIG. 123.—"MOONLIGHT MUSHROOMS," AS SKETCHED BY A JAPANESE ARTIST.

The volumes begin at the end with an introduction. Vol. I. commences with an illustration and description of what is called the "First Mushroom." This is a Lactarius, and is said to have the best scent of all Mushrooms, and with a taste both sweet and cooling. It is not poisonous, and grows in Pine plantations. The next is the "Red First Mushroom," another Lactarius; it is described as red, clean, and amiable, with the best taste. This is followed by what is called the "Dancing Mushroom;" the illustration greatly resembles our Lentinus cochleatus; both size and shape are said to be "various," but the usual shape is "like a man dancing;" this explanation is, however, qualified by a second, which says that when bears find it they dance, and that they are very fond of eating it. It is stated to have medical properties, and to have "good effect if eaten by a sufferer of piles." This is followed by the "Violet Dancing Mushroom," the popular Japanese name being the "Dancing Ape." The taste is said to be "light," but a blackish variety is considered the best for culinary purposes. Next there is a "Yellow Dancing Mushroom," with a "sweet and bitter" taste, an inferior species of poisonous Mushroom. A white Hygrophorus is next illustrated, and then a "Quercus Mushroom," which is inferior when dry, but when fresh better, and good as a "dainty for carouse." It is said also to be an antidote "for the poison of fish and concoction." A group of certain fungi is somewhat ambiguously said to be like a "sloping fence," then a subterranean species is represented — Rhizopogon rubescens; next a Hydnum, than a pallid, violet Clavaria. This, we are told, if eaten in quantities, "causes stomach-ache and purge." Next we have "Buddha's-hand Mushroom," and two pages of description and illustrations of what is called the Hukiyo-take, or "Moonlight Mushroom." The illustrations seem to represent our Agaricus fastibilis, a well-known poisonous species often confounded with the true Mushroom, and which sometimes appears on Mushroom-beds. If it is not A. fastibilis, it is a very close ally. We here reproduce a copy of one of the drawings of this species, partly to show the excellent draughtsmanship of the Japanese artist, and partly to show how cleverly the habit of the species is given (fig. 123). The scaly stem is very characteristic, so is the ragged margin of the pileus, and the habit of growing in rings or parts of rings is well shown.

A second illustration, not reproduced, shows two large plants just as we find them in this country. The results of eating this fungus are also identical in Japan and Britain, for the author says all who have eaten it get "stomach-ache, vomit and purge." It seems to have been eaten by the author by accident, but he, with others, avoided disaster by using Birch-bark, "which cured them in narrow escaping;" then we found this fungus to be very venomous. Happily," says the author, "I escaped. To be cautioned. If a man takes this fungus by mistake, it is sure to cause vomit, stomach-ache, or lunatic-frolic; if severe, man is killed." The name of "Moonlight Mushroom" is derived from its phosphorescence at night. It has a second popular name, viz., Huyasuke-take, because in "ancient ages" one Huyasuke was killed by it. The plant, we are told, is to be distinguished with caution, and that, generally speaking, the poison of Mushrooms may be cured with a "decoction of Birch-skin." In sudden cases, "powder of clay-ware" is recommended; "also laying the body on the ground" is said to be "a good cure." This very simple "cure" might be tried by some of the members of our mycophagous clubs, and the results reported to the *Gardeners' Chronicle*. After the "Moonlight Mushroom," a good illustration is given of what appears to be the allied Agaricus longicaudus; this is said to be "very venomous and fatal," just what we should expect of the plant here. Further on, an illustration of another Lactarius is given, and a "Fungus of a Church," because "a monk first ate it, and then many followed him." A plant which seems to be Agaricus melleus is given, the taste of which is said to be "refreshing and fine enough for eating." A certain fungus is said to be the "Oshuggarushi" of the Aino-tribe; this has a "light taste." A crimson Russula is the "Kenekarushi" of the Ainos, with a "light, slightly poisonous taste. The first volume concludes with illustrations and descriptions of Clavarias.

Volume II. commences with an excellent illustration of Nyctalis parasitica, which is said to be poisonous, and "not counted a culinary article." Then an Amanita or Volvaria, which is said to be "very venomous and kills man." Next, Agaricus Vittadinii, and the "Moonlight Mushroom," again. Another Amanita is then given, "very venomous and fatal." Further on a Starry Puff-Ball is given; it is used, we are told, for "stopping blood." Another Starry Puff-Ball is illustrated further on, and named the "Deaf Fungus," because if it be "philliped," yellow powder comes out, which causes deafness if it enters the ears. Passing on we come to the "Grasping Fungus;" we are told that if it is held in the hand it shrinks, and if the hand is off "soon inflates." An Agaric, which looks like our Agaricus subinvolutus, is called the "Maple Mushroom," and the "Jobeni Karughin," of the Ainos, the description of which states that "one does not stop laughing" after eating it. Other Amanitas follow, one, the "Fly-catcher," is said to be venomous, "and surely flies die by eating it." Aseröe, Clavarias, and a Boletus follow, and a Polyporus found on the Mulberry. This, it is said, "cures very well the stubborn paralysis." A tinder Polyporus is illustrated, and a "Red Hardy Polyporus." Polyporus officinalis of the Larch is said to have a bitter, strong taste, and to be good for "curing the bellyache." It is satisfactory to learn that one exceptional fungus cures the "bellyache," the majority certainly cause it. A few other plants, not fungi, are illustrated and described, such as Ophioglossum, Gastrodia, Orobanche, &c.

The two small volumes are well worthy of careful attention, both for their illustrations and descriptions. *Worthington G. Smith, Dunstable.*

FÜHRER DURCH DEN KÖNIGLICHE BOTANISCHEN GARTEN IN MÜNCHEN. Von Dr. K. Gœbel, Professor of Botany.

This is a small guide-book to the Botanical Gardens, Munich, indicating the plants which possess special interest to the visitor. This botanical garden, since Dr. Gœbel induced the municipality to afford it monetary support, and indicated its importance as a teaching establishment, is much visited, especially on Sundays and holidays, and in summer till late in the evening, this last a circumstance scarcely to be found anywhere else, and least of all in Germany. This garden is not, like most of the botanical gardens of the country, a university institute, but belongs rather to those bodies which are under the general direction of the Royal Academy of Science and Art, but which are in close connection with the university. The garden was founded by King Maximillian Josef I. in 1807, whilst the university was not transplanted to Munich from Landshut till 1826.

The garden was laid out under the direction of Prof. Franz von Paula von Schrank. The garden consists of two divisions, the "large" and the "small," separated by the Sophienstrasse. The guide-book affords an idea of the cost of the up-keep, and gives the rules to be observed by visitors; then follow brief chapters descriptive of the various portions of the garden, beginning with the small garden, the more remarkable plants being mentioned, and their peculiarities and attributes alluded to. A useful manual for the visitor or student who does not want to waste time in discovering the whereabouts of such things as interest him.

HOME CORRESPONDENCE.

COLUMBINES.—I do not think these hardy flowers have ever been regarded as florists' flowers, although remarkable improvements have been effected in them since Mr. Douglas first set the ball rolling by intercrossing some of the charming species that are even now none too widely grown. Since then others have taken not only the species but their hybrid products in hand, and without exercising much of the breeder's art, yet by constant selection and such intercrossing as Nature furnishes, there have now been produced strains of the most remarkable beauty as well as varied in colours. It is one of the happy characteristics of the breaks, that they all present in a high degree the long-spurred form, without which Columbine flowers seem so stiff and formal. Very much has been done to give variety to the old garden forms, but in no case that has come under my notice have the long spurs been produced from them. One cross I made some years ago between a chrysantha and one of the garden forms resulted in the production of flowers that were not only absolutely spurless, but produced corollas so expanding that the flowers closely resembled small Clematis blooms. The product was curious, but not pleasing; but of the true strains that were obtained from the best species, there can be no question as to beauty that is to me marvellous. When last summer I stood in the midst of a huge breadth of these Columbine hybrids, on Messrs. Cannell's Eynsford farm, I could realise that no greater floral beauty could be furnished by any other plants. There are many combinations of colours found that I had not previously seen, and I literally revelled in the privilege to go through the break, and indicate which of the many thus in bloom seemed to be most worthy of selection. Seeing that these plants seed freely, are so easily raised from seed, and once strong, bloom so finely for several years, how is it that we do not find them in all gardens? Generally they are not found at all. Many gardeners do not seem to know of them. It is a favourable time to refer to them now, because we are near the season for sowing. The month of May is a good time, and the sowing may be made out of doors on good soil and in broad-cast form, or in shallow drills, as may be preferred. Seedlings thus raised and transplanted into beds or borders, wherein to bloom in August or September, make fine flowering plants the following summer. One result of intercrossing species has been in the hybrids greater strength and floriferousness. There is no suspicion of barrenness in the products, because the original species are so closely allied. Certainly the intercrossed product has been found in a glorious floral addition to our gardens. *A.*

MR. MALCOLM DUNN.—An announcement of the sudden death of this distinguished and estimable Scotch gardener has come as a severe shock to all who knew him. Truly of him may it be said that "in the midst of life we are in death," for all might have given him threescore and ten years of life, so hale and hearty did he appear to be. It was but the other day his name appeared as one of the chosen three judges for the great Grape class at Shrewsbury, next August, but the famous Shropshire Quarry will not hold him again, and a melancholy duty is cast upon the Home Committee of selecting another colleague for Messrs. Thomas and Crump. Scotchman as he was, horticulture claimed him as her own, and horticulture knows no nationality. It was, without doubt, as a distinguished Scotch gardener all the same, and as a representative horticulturist of the race beyond the Tweed, that he was selected to receive one of the Victorian Medals of Honour. During two years from the installation of the medal, none of the sixty has died till now, and Malcolm Dunn is the first to travel the road of honour into the realms of the great unknown. The council of the Royal Horticultural Society will have a difficult task to perform in worthily filling the dead gardener's place, but in any case they can barely ignore Scottish claims if advanced. It was easier to select sixty than to select one out of numbers of good men. Doubtless, Scotland will strive worthily to raise a memorial in honour of the departed. It was his lot to follow in the path and work of one of Scotland's greatest gardeners, William Thomson. It will need a good man to worthily sustain as Dunn's successor, his and Thomson's reputation, and that of famous Dalkeith. *A. D.*

CUPRESSUS MACROCARPA.—In the villa gardens round about Torquay this Conifer is put to valuable use, and if proper attention be afforded, it admirably answers its purpose. Many of the villas are built on undulating land, and the roofs of some are almost in a line with the ground floors of those just above them on the hills. It follows that the garden of one is often open to those of its neighbour, and even to those placed on level ground, there is always a desire on the part of the occupants for a certain degree of privacy and seclusion, so essential to the enjoyment of a garden. The garden-walls are about 3 or 4 feet high, with soil on the inside borders almost level with the top of the wall. On this a number of Cupressus macrocarpa are planted, 2 or 3 feet apart, and being a quick grower, the lower portion soon thickens; and when the plants have grown some 6 or 8 feet high the leaders are cut away which encourages the thickening of the top. Ere, however, this finishing part is permitted, it is necessary that a strong iron railing be run the whole length of the intended hedge, and stout iron standards and stays well secured to the wall as well as the border inside with a couple of rails, one about 2 feet from the ground, and the other 5 feet. These, of course, are firmly fixed to the uprights, so that when finished the whole is strong and able to resist the winds which will, by-and-by, try the hedge. The plants are secured to this iron railing, which is soon hidden, and as they reach the height previously mentioned, topped and clipped, a most compact and beautiful hedge is formed which entirely shields everything in the garden from the gaze of passers-by or from neighbourly observation. The hedge may be permitted to measure 3 feet through at the base, gradually sloping in height till the top, perfectly level, is about a foot in thickness. Some run just 6 feet high, 2 feet at the base, sloping gradually to the top. The bright, pleasant green of the young shoots just at the present season makes such a hedge singularly attractive. Some of the owners, I notice, have made provision for the little gaps that occasionally occur in the lower part of the plants by planting a row of Euonymus between the Cupressus and the walls; these are kept dense and compact by constant clipping. The variegated forms as well as the common Euonymus are used, the whole making a very pretty and complete bank of vegetation, always green, and most attractive. The beauty of such a hedge is, of course, enhanced and preserved by regular clippings—twice a year they should be attended to by one who thoroughly understands his work. Of course, any one can use a pair of clipping shears; but where straight and curved lines and level top are to be maintained, it is very desirable that one who is somewhat of an adept at his work should be always permitted to do it. In the hot summer seasons in the south of Devon, and on raised banks and borders, it is necessary that the hose-pipe be used, and abundant supplies of water constantly afforded, as only by such means can the health of the hedge-plants be maintained. *W. S., Exmouth.*

THE PEAR MIDGE.—The mischievous insect, "Diplosis pyrivora" is again infesting our Pear-trees in considerable numbers, notwithstanding all our preventive measures taken every year. These consist of sending men to pick off the tiny lop-ended or deformed Pears, and burn them, which is done by the bushel. This is repeated several times, and to make doubly sure, fresh hot gas-lime is strewn under the trees. In order to prevent our neighbours' crop of midges invading this garden, all of our trees were sprayed daily, weather permitting, for a fortnight previous, and right up to the time of the opening of the flowers, with a mixture of Quassia and soft-soap; but this has not been successful, and it made apparently little difference. The adult midges are very small, and not therefore readily distinguishable. I have been advised to strew kainit under the trees at the rate of 4 oz. per square yard, to receive fallen fruit which might contain larvæ, as well as such of the larvæ that have burrowed their way through the sides of a fruit, with the object of hybernating in the soil. This experiment is having my careful attention, for I think no trouble too great that will enable me to master the Diplosis, which will otherwise render Pear cultivation at Madresfield impossible. It is a pity that many persons neglect to take precautions. It is well for every gardener to examine his Pear-trees, and if any of the fruits are seen to be bottle-shaped, and not of a symmetrical form, he should slit them down through the core, when, by the help of an ordinary lens, the larvæ will probably be found. It is curious that Williams' Bon Chrétien and all the allied kinds, such as Beurre de l'Assomption, Beurré d'Amanlis, and Souvenir du Congrés are affected much more than the later-flowering varieties. I am of the opinion that the Pear-midge propagates in neglected orchards, and is carried by the wind in the same way as the winged aphis, when disturbed by my neighbours the Hop-growers, especially in the autumn or late summer. *W. Crump, Madresfield Court Gardens.*

THE WEATHER NORTH OF THE TWEED.—This gets worse and worse, though we are within a week of the end of May; and so far as we have gone, the weather throughout has been more like December or March than May, with its dew-spangled flowers of freshness and fragrance. The general opinion is that already the produce of field and garden is some three weeks behind the calendar, and growers are beginning to ask anxiously about the beginning of the forcing-weather so much needed to enable our crops to run abreast of our calendars. Hitherto our many changes of wind have brought us few or no changes of weather. The west winds have proved about as cold, and far stronger than the east, and the south winds have not blown long enough at a time to temper the severities and harshness of those from the north and north-east. Though we have had little snow save those showers and storms that converted such large areas into sheer winter on May-day, the rains have been almost as cold as sleet or snow; and the frosts, though not severe, have arrested growth in all tender crops, in many cases cut back most precocious Potatos to the ground-line, entirely arrested the growth in the open air of young seedling flowers and vegetables, and very much thinned the forward blooms of the Peach, Nectarine, Apricot, Plum, Pear, and even of the Cherry, the blooms of which are hardier than either. The lateness of the season promises to prove a decided advantage to the most important crop of all our fruits—the Apple. The Apple-trees and bushes look remarkably well in most districts, and promise to be the fruit crop of the season, as they were also last year. Fruits of the Gooseberry and Currant situated on the extremities of the shoots have been frozen; but, on the whole, our bush-fruits of all kinds give promise of a full crop. Strawberries seem scarcely to promise an average yield, and not a few experienced cultivators hold that a Strawberry crop is seldom as good a one after a mild, wet, as after a hard winter. *D. T. F.*

A LARGE PLANT OF THE CLIMBING DEVONIENSIS ROSE.—There is here a plant of the climbing Devoniensis Rose, which covers the entire span-roof of a greenhouse 40 feet in length and 20 feet in width. The plant is in perfect health, and yields hundreds of Roses every year. I know nothing about its age, but should suppose it is considerable, the stem at 2 feet from the ground being fully 12 inches in circumference. *J. Tweedie, Newbank, Edinburgh.* [Not so very large. Ed.]

FLORISTS' FLOWERS.

HINTS ON POTTING CHRYSANTHEMUMS.

Some cultivators make a rule of potting the plants during a certain week in May or June. Rigid adherence to a particular date may answer well in some seasons, but as a rule it is not a praiseworthy arrangement. The best practice is to take into consideration the state of the plants. If the pots in which the plants are growing be 5 or 6 inches in diameter, and full of roots, then they should be at once transferred to larger pots. Chrysanthemums should be free from checks to growth at all times, and if permitted to remain in pots until the roots have become matted, this necessary principle will be violated.

In the cultivation of Chrysanthemums for the production of large blooms, there is much difference of opinion amongst growers as to the size of pot necessary. Some prefer those 10 inches in diameter, others will use pots of 7 inches diameter. But in the latter case one bloom only is allowed to each plant, and this practice is largely increasing. As a general rule I prefer an intermediate size, say a 9-inch pot; and for weakly growing kinds, pots an inch smaller; extra-strong growing sorts might be given 10-inch pots. But after all, very much depends upon the after treatment the plants receive.

In respect of compost, a very suitable one for the bulk of varieties would be composed of three parts fibrous loam to one part half-decayed horse-manure, with sufficient sand and charcoal added to ensure porosity. A further addition may be made of 2 lb. of Thomson's Vine and Plant Manure to every bushel of the compost. Well-drained pots are a necessity. Press the soil firmly into the pots, especially about the ball of earth containing the roots. Take care that the roots of the plants to be potted are thoroughly moist before being removed from the old pots, it being difficult to afford water for a little time afterwards without souring the new compost. *E. Molyneux.*

The Introduction of the Fancy Pansy.

Reverence for my old friend, the late John Salter, of Hammersmith, and admiration of his work, is my excuse for questioning Mr. R. P. Brotherston's statement, on p. 307, that "about 1860 John Downie introduced the Fancy Pansy from Belgium." This sentence is no doubt meant to give John Downie the credit of having first introduced the Fancy Pansy to the United Kingdom. Happily, I have documentary information which shows that the Fancy Pansy had its origin at Shepherd's Bush.

Sixty years ago John Salter resided at Shepherd's Bush, and was an enthusiastic cultivator of florists' flowers. The Pansy was then undergoing improvement at the hands of Thompson and others, and had led to the ingathering of a harvest of good things. At that time a widely popular exhibition of Pansies was held at Hammersmith, and John Salter, then an amateur cultivator, grew improved and probably exhibited Pansies. When, in the early forties, he went to Versailles, France, and established a nursery there, he took with him his favourite Pansies, but the heat of the French summers and the cold of the winters did not suit them so well as the English climate. Still, he continued to raise seedlings, and being a dealer in novelties, no doubt distributed them in the course of business. The French florists, who could never quite fall into line with Glenny, Brown, Hale, and other raisers of that period, appeared to have favoured John Salter's seedlings. By 1847 he had raised some curiously striped and blotched varieties, seed was saved from the best of these, and when early in 1848, through the outbreak of the French Revolution in that year, Salter gave up his French establishment and came to England, bringing with him his best selections of seed, which were sown by him at his Versailles Nursery at Hammersmith. In 1850 he brought his strain of Pansies into prominence by offering varieties for sale, not exactly as show flowers, but as deserving of recognition on account of their fantastic colours. In 1851 Salter (whose nursery was close to Addison Road Station, and was much visited by foreigners who came to London) offered three named varieties for sale, viz., cœrulea striata, white and blue; Mars, bronze and yellow; and Novelty, yellow, striped with maroon. In 1852 sixteen new varieties were sent out by Salter, all of his own raising; and in 1854, other and improved varieties were distributed. That the term "Fancy Pansies" is of much earlier origin than is generally supposed I establish by giving an extract from John Salter's catalogue of 1854. "Fancy Pansies: This class was first brought into notice in 1850 by John Salter, and were then not offered as show flowers, but for their fantastic colours. Since that time they have been greatly improved in form, and the new varieties of this season will be found larger, more regularly striped and blotched, and a great addition to this distinct and attractive class, which promises to become as popular as the fancies of any flower." There were Fancy Dahlias, Fancy Pelargoniums, &c., in cultivation in that day as there are now.

By this time, M. Miellez of Lille, who greatly distinguished himself as a raiser, had sent out one or two very fine varieties. Quite lengthy lists of new varieties appeared in Salter's catalogue for 1857 and 1858, in the latter many Fancy Pansies were named, including Magpie, a very distinct type, clear blue with white blotches, which, it is to be feared, is now very difficult to be obtained in its original character. It is said to have been discovered growing in a corn-field, and forty years ago it was also known under the synonyms of Mazeppa, Paul Pry, Wonderful, and La Pie.

An enormous impetus was given to the development of the Fancy Pansy in this country about 1858, when Mr. A. Henderson, then of Wellington Road Nursery, St. John's Wood, while travelling in France, discovered some new forms of blotched Pansies. As he could not successfully cultivate them in the then rapidly-growing district of St. John's Wood, he sent them to my brother, William Dean, who had but recently established himself in business as a nurseryman at Shipley, near Bradford, to grow for him in the cooler and moister climate of Yorkshire. These varieties were great improvements upon what had previously been seen, and they were also the production of Mons. Miellez. The first batch sent to Shipley were Eva, Bob, floribunda, Cerberus, cœrulea alba, Eckard, and others; and they were followed by Prince Imperial, Ali Bey, Parpaillot, Miracle, Agnes Sorrel, Napoleon III., and Massaniello. As I spent the autumn of 1860 and all the spring of 1861 at Shipley, these Pansies came under my care, and I have a vivid recollection of them. In 1861 came Belle Esquermoise, Louise Miellez, Distinction, and others; the next year came Octavie Demay and Nœmie Demay, and with these and the death of Mère Miellez the supply from France came to an end.

Meanwhile, W. Dean had commenced to raise seedlings, and the first batch sent out by him was in the autumn of 1861, and consisted of Princess Alice, Donald Beaton, Etoile du Nord, Tiger, &c. In 1862 and 1863 new batches of varieties were also distributed, and the term "Belgian Pansies" was applied to all that my brother raised and sent out.

PORTRAIT OF THE LATE JAMES KELWAY.

In Scotland, John Laing, then of Dysart Gardens, was the first to take in hand this type of Pansy, and his first seedling of note was a bright-coloured flower named Professor Berkeley. On joining Messrs. Downie & Laird in business the firm took up the culture and improvement of the Belgian Pansy with spirit, and despite the prejudice against them on the part of those who valued the old type of English show Pansies—yellow grounds, white grounds, and selfs—the Belgian sorts made headway; their latent possibilities were recognised, and the future foretold for them abundantly realised. Brilliancy of tint, variety in colour, richness in expression, solidity of substance, and vigour in growth, are the leading characteristics of the fancy Pansies of our day. Their robustness is in marked contrast to the constitutional debility of many of the English show varieties. *Richard Dean, Ealing, W.*

Obituary.

Mr. James Kelway.—The death is announced of Mr. James Kelway, senr., of the Langport Nurseries, on the 17th inst, at the ripe age of 83 years. He was the founder of a firm widely known for its enterprise, and for its success in the improvement of some of our most popular flowers. Born at Westholme, near Shepton Mallet, on Nov. 2, 1815; he was educated at Wells and Wellington, Somerset. As a lad he was noted for his cleverness and his painstaking application to his studies; he was desirous of assisting the best interests of others, and at the age of sixteen had gathered about him a class of some eighteen lads whom he nightly instructed in the elements of learning. From his youth upwards, flowers and their culture greatly interested him, and it is on record that he was an exhibitor at a flower-show at Glastonbury at the age of fifteen, and he was so successful that twelve first prizes and five second prizes fell to his lot out of twenty-three entries. It was his first attempt as a competitor; his success was prophetic of his future career. At the age of eighteen, Mr. James Kelway had entire charge, with a staff of men under him, of the Gardens of Dillington House, near Ilminster, and lived there for the space of seventeen years. In 1850 he purchased the old dwelling-house (now the offices of Messrs. Kelway and Sons) and an acre or two of land, which formed a small nursery, from a Mr. Isaacs, at Huish Episcopi, the parish adjoining Langport, removing here with his family in 1851. This formed the nucleus of the present nursery of 200 acres, having on it four dwelling-houses, and several cottages, and farm buildings. It is worthy of note that the Gladiolus, the flower with which the name of James Kelway is closely and successfully associated, attracted his attention for the first time at Glastonbury, where in 1830 he saw a specimen of Gladiolus psittacinus exhibited, and a desire to cultivate and improve it was born in him. On commencing business near Langport, he paid special attention to the hybridising and culture of this flower, and early in the sixties commenced that series of successes in the exhibition of it, which before long made the name of Kelway known throughout the Kingdom, and ultimately throughout Europe, America, and the colonies. In thirteen years it may be said of him that he was pre-eminent in this particular field, and the International Exhibition held in Paris in 1878 proved that his productions in respect of novelty and quality were second to none in Europe. In the year 1866, he distributed new varieties of Gladioli, which his patience and skill as a hybridist was enabling him to produce for the enrichment of gardens. The *Gardeners' Chronicle* in 1891, in the course of a review of the productions of the preceding fifty years, remarked:—"There are two plants whose names occur as deserving of unstinted praise, two plants in whose cultivation immense advance has been made, and before whose state of perfection criticism must bow with bated breath. Each of these plants has been taken in hand and perfected by one man in particular, which is a rather remarkable fact: the men and the flowers are Veitch and the Amaryllis, Kelway and the Gladiolus." How many unique varieties have been produced and exhibited by James Kelway up almost to the period of his death let the records of the Royal Horticultural Society testify. It is with the Gladiolus in particular that he was able to accumulate that large collection of medals, cups, &c., awarded to him from time to time.

It must not be supposed that the Gladiolus was the only plant so successfully improved by this remarkable man. It is claimed for him that he was among the first in the work of improving the Cineraria, as also in improving the Frame-Cucumber, some popular varieties having originated at Langport. Later in life the Pæony, the Delphinium, the Pyrethrum, &c., came under his care; the second of these especially being improved by the firm in a really wonderful degree. It was well and truly said of James Kelway in 1884, that "he is a truly representative man, whose whole life has been given to the culture of flowers." In 1890, at the request of the Council of the Royal Horticultural Society, Mr. Kelway delivered a lecture on "The Gladiolus" at one of the Society's meetings.

It is only possible in a limited space to touch upon a few of the flowers cultivated with so much success by the Langport firm; suffice it to say, that a large and remunerative business has been built up, which will be continued by sons and grandsons along the lines laid down by its once active head. Not less remarkable was his activity in public life. As churchwarden, an office he held for the space of 33 years; as a member of the School Board; as a member of the Langport Town Trust, and in other ways he devoted his energies to the well-being of his fellow creatures, and he has closed his active career, carrying with him to his grave the regrets not only of a wide circle of friends and acquaintances, but also with those of the extensive district throughout which he was so widely known.

Mr. James Kelway was twice married, his first wife dying in 1870; and he was married for the second time in 1872. He died surrounded by the members of his family, who were ever to him a great comfort, especially in his declining years.

NURSERY NOTES.

MR. F. SMALE'S, TORQUAY.

The Torre Park Nursery, being but a town branch of the larger nursery on the Barton Road, some three miles from Torre Station, it has not a complete collection of plants, but amongst those noticed on a recent occasion was a grand collection of Cannas. The growth of the plants was sturdy and strong, and they will be sure to flower well when planted in the open ground.

Another special feature was the zonal Pelargoniums. These are stout, sturdy plants now in flower, among them being varieties with blooms of unusual size and vividness of colour. Here was Nicholas II., crimson scarlet; J. M. Barrie, bright pleasing crimson; W. E. Corden, clear scarlet, with bright eye, very fine; Virginia, pure snow-white; Sir Henry Irving, rosy magenta, very free flowering, and dwarf in habit; Condé, deep crimson, very large; Conan Doyle, clear salmon pink; Herrick, glowing crimson, very large and of good form; Lilacina, a very distinct shade of lilac, a choice variety; Sir J. Kitson, purple magenta, with white centre, free grower and bloomer; Ian Maclaren, deep salmon, fine in form and colour; Madame Bruant, white, netted purple, with purple band, very distinct; Southey, rich vermilion, white, a blotch; Wilhelmina, rich salmon colour, with scarlet centre, producing trusses of large size.

It is some time since I saw such perfect specimens of Gymnogramma schizophylla gloriosa as were growing here in 7-inch pots. The numerous fronds, with their finely-divided pinnæ, overlapped each other, and in some measure, by their density and compactness, reminded one of Todea superba. *W. S.*

SOCIETIES.

INTERNATIONAL HORTICULTURAL EXHIBITION AT ST. PETERSBURG.

May 17.—The third International Flower-show held at St. Petersburg was opened by the Czar in the Tauride Palace, a building comprising vast saloons built by Catherine II., and subsequently presented by her to one of her generals. Considering the great climatic disadvantages under which the gardeners of this country suffer, the show is remarkably fine; and though many of its best features have been contributed by Belgian, French, and German growers, who, at great expense, have sent many large groups, yet has it rarely been the good fortune of either Mr. Ker or myself to see so many hundreds of fine Tea and Perpetual Roses grown in pots as the local growers have massed in various groups.

The great body of the main saloons, especially that portion near the royal platform, is filled with large groups of Palms from the imperial gardens, some of these, and notably the Caryotas, being really magnificent specimens. In conjunction are standard Rhododendrons, well-flowered, from M. Moser, of Versailles, and masses of Hydrangeas from Sallier, of Paris. The French section is the strongest, many notable nurserymen being well represented.

MM. André and Martinet have very large and elaborate plans of landscape gardening; and more than one French amateur has sent the best of his Orchids.

The English exhibitors are not many—Messrs. Ker, of Liverpool, with Amaryllis; Messrs. Sander, of St. Albans, with a collection of general stove plants; and Messrs. Veitch, of Chelsea, with insectivorous plants, are the sole representatives of British horticulture.

The Belgians are strong in Anthuriums, Azalea pontica seedlings, Araucarias and Palms; and Messrs. Peeters, of Brussels, have sent a really remarkable collection of Orchids, containing some of the latest and most interesting hybrids. Lilacs and Azalea indica, grown as standards, are masses of flower, and relieve the darker corners of the great halls, whilst in the grounds outside are many groups of variegated and choice Coniferæ, and examples of fruit-tree training, such as our French cousins alone produce.

Considering that in shaded streets there is still snow, and that bitter easterly winds prevail, one can but honour the energy of the directors of the Exhibition in having produced such a show, which, even when judged by the standard of those seen in Western Europe, is of the highest excellence.

The Emperor and suite passed rapidly through the exhibition, and in the small English department Mr. Veitch had the honour to explain the marvels of the Nepenthes, Droseras, Dionæa, &c., of which his firm had sent such a notable and rare collection. The splendid Amaryllis of Messrs. Ker, Liverpool, gave brilliancy to the other groups, and were also warmly praised and admired. Mr. F. Sander, by permission of the Czar, dedicated a new Palm, Romanovia Nicölai, to his majesty. *J. H. V.*

ROYAL HORTICULTURAL.

Scientific Committee.

Present: Dr. M. T. Masters (in the chair), Dr. Müller, Rev W. Wilks, Mr. E. F. Im Thurn, and Rev. G. Henslow, Hon. Sec.

Diseased Hemerocallis, &c.—A leaf was received bearing decayed spots, apparently due to fungoid growth. This, together with a Peach diseased by a form of mildew, and Apple twigs with knots, were forwarded to Dr. W. G. Smith for examination.

Podisoma on Savin.—Dr. Masters exhibited specimens of this fungus, which gives rise to Rœstelia cancellata on Pear-trees.

Æcidium grossulariæ.—He also brought specimens of the "Gooseberry cluster-cups." It occurs on leaves and fruit of the Gooseberry and Currant. In some seasons it is of frequent occurrence.

Morel.—Dr. Masters also showed a small Morel, found—as is somewhat rarely the case—growing singly. He recorded the fact that after two Poplars had been blown down in Mr. Masters' garden at Canterbury in 1887, Morels grew every other year round the stumps. Mr. Im Thurn observed that the Morel was a common fungus on the Wiltshire moors among Beeches.

ROYAL BOTANICAL AND HORTICULTURAL OF MANCHESTER.

May 19.—The usual Whitsuntide Exhibition was opened on the above date at the Botanical Gardens, Old Trafford. Established about thirty-seven years ago, these exhibitions have been among the most prominent and successful in the United Kingdom.

This year, however, the exhibition fell short of its usual excellence, partly, perhaps, from the backward season, but certainly in a large measure to the apathy of local cultivators. There may be good reasons for this, for we cannot think it is due to a slight reduction in the prize money offered in one important class for Orchids. At most shows where Orchids are a feature, the local growers are pleased to exhibit their plants without any thought of prize-money.

At the Temple Show of the Royal Horticultural Society, for example, such amateurs have exhibited as Baron Sir H. Schroder, Sir Trevor Lawrence, W. Gurney Fowler, Sir Fredk. Wigan, H. S. Leon, and numerous others. They do this for the love they have for horticulture, and their brethren further north might well imitate them. The collections of Orchids in and around Manchester cannot be excelled in any part of the world, but on this important occasion the owners of them have certainly failed to display this superiority.

We have missed for a few years contributions from Mr. Fred Hardy's collection, one of the best in Manchester; this year we miss the Elijah Ashworth's, Mr. Warburton's, Mr. Statter's, and the beautiful collection which Mr. W. Thompson, of Stone, Staffordshire, has usually sent. The show is a protracted one, being open from the Friday preceding Whit Sunday until the following Thursday evening. The Orchids are staged in a heated house.

Orchids.

In the competitive classes, Mr. James Cypher gained 1st prize for a group of plants, which was very tastefully arranged, partly on stages and partly on the ground. Many fine specimens of Lælia purpurata, Cattleya Mendeli, C. Mossiæ, very fine, splendidly-grown plants of Oncidium concolor, and Sophronitis grandiflora. Many interesting varieties were also in the group, including Lælia Digbyana, of exceptional size; very fine forms of Cattleya Aclandiæ, one of a dark chocolate colour entirely, no bars of any kind being present. Mr. John Robson, Bowdon, Manchester, gained 2nd honours, with a fine group of well-grown plants, among which were two fine forms of Odontoglossum crispum.

For a collection of Cattleyas and Lælias, the 1st prize was awarded to Mr. J. Cypher; Messrs. Heath & Sons were 2nd.

For ten specimen Orchids in bloom, Thos. Harker, Esq., Fallowfield (gr., Mr. Mulloy), was 1st.

Messrs. Charlesworth & Co., Heaton, Bradford, Yorks, made a fine display of good and choice Orchids, amongst which was a collection of semi-established plants of Odontoglossum crispum of a very good type, and which was stated to have been gathered from Messrs. Charlesworth's own mountains. A noticeable plant in the group was Odontoglossum "Harvengtense" which is supposed to be a natural hybrid between O. triumphans and O. crispum; this is doubtful, and the lip is the only portion of the flower which suggests the slightest trace of the latter parent. It is, however, a very good plant, and has found its way to a good home for Odontoglossums. O. hystrix magnificum had fine colour and size, and O. crispum "var. Georgiana" is a flower of pretty form and markings (Gold Medal).

Messrs. John Cowan & Co., Ltd., The Nurseries, Gateacre, made an excellent display, occupying a length of about 40 feet of wide staging. Noticeable in the group were some very peculiarly marked varieties of Lælia purpurata, three fine plants being almost pure white, with the exception of faint pencillings of lilac in the labellums. Many good forms of Cattleya Mossiæ were shown, one called C. M. magnificum being the best. Cattleya citrina was shown splendidly in this group (Gold Medal).

L'Horticole Coloniale (Linden), Brussels, made a grand show with about fifty plants, every one of which was of a choice variety. Odontoglossum crispum var. "Countess of Derby" was thought to be the *pièce de résistance* of the group, and it certainly is an elegant flower, a branched-spike bore twenty flowers of good shape, medium size, and peculiarly marked with small round spots. Many forms of O. × Adrianæ (O. crispum × Hunnewellianum) were displayed, varying in colour from very pale yellow or dirty white flowers to the deep coloured forms of O. sceptrum. There were fine forms of Miltonia vexillaria, one almost pure white called "candidula." The Belgians seem still to be able to show us how to grow M. vexillaria, as well as many Odontoglossums.

First-class Certificates were awarded to Odontoglossum crispum var. Countess of Derby and O. Adrianæ var. leopardinum.

Awards of Merit were given to O. hybridum var. fascinator, O. Ruckerianum var. Queen Victoria, Miltonia vexillaria var. vittata, and M. v. candidula (Large Gold Medal).

Messrs. Hugh Low & Co., Bush Hill Nurseries, Enfield, showed a small but choice group of plants. Odontoglossum Andersonianum giganteum was thought worthy of a First-class Certificate by the Orchid judges, a similar Award being given to a fine plant of Cattleya intermedia alba. The same firm showed a good form of Odontoglossum × excellens, and a pretty white form of O. Pescatorei, called virginalis (Silver Medal).

Duncan Gilmour, Esq., of Sheffield, staged a good group of plants, principally consisting of Cattleya Mossiæ (Silver Medal).

MISCELLANEOUS.

There were classes for Stove and Greenhouse Plants, Groups of Miscellaneous Plants, arranged to produce effect; Roses in pots, Ferns, Gloxinias, Calceolarias, Begonias, Caladiums, &c.

Messrs. **Waterer** & Son, Bagshot, Surrey, had one of their usual grand displays of Rhododendrons, and a large space was occupied by their exhibit. A novelty, named Pink Pearl (Award of Merit), caused a sensation on account of its fine blooms and warm rose colour.

Messrs. **Webb** & Son, Stourbridge, put up a group of herbaceous Calceolarias, of a good strain.

Messrs. W. **Clibran** & Son, Altrincham, exhibited herbaceous and greenhouse plants, brightened by pretty clumps of Salvia splendens.

Messrs. **Dicksons**, Chester, staged a nice group of a new yellow Carnation, and a collection of Auriculas (Silver Medal).

Mr. J. J. **Upton**, The Nurseries, Irlam, sent an exhibit of his strain of Gloxinias, which was unsurpassed by any shown from private collections (Silver Medal).

Messrs. W. & J. **Birkenhead**, Sale, had an interesting collection of Ferns (Silver Medal).

The Misses **Hopkins**, Knutsford, Cheshire, had a very pretty table of Violas and Auriculas. A. Golden King is well worth growing, on account of its very free-growing and flowering habit.

FRUIT GROWING IN KENT.*

(Concluded from p. 324.)

In the Future.—Without in any way venturing to prophesy we have seen enough of the success of the best fruit growers, to outline in some degree the probable course of commercial success in the future, for it is to the newly-planted orchards, where the sorts are of the best for their special purposes, and where clean cultivation obtains, that we must look for our chief supplies in time to come. In America and Canada, they consider 15 years the average life of a paying orchard; the trees are then destroyed, and a fresh start made. In this country 25 to 30 years may be considered as the outside limit, and by that time the available nutriment in the soil may be considered to be exhausted by the standing trees.

It will, therefore, be well before that time expires to provide other orchards to replace the condemned patches. This may appear to many a drastic proposal, but the stimulating manures now given tend to strong sappy growth, therefore I think I have not overstated the case. Again the public is fast being educated to distinguish between good and inferior fruits, and growers will find their future profits to lie in producing examples of the finest sorts.

At present, colour is the market factor in Apples more than quality, red and yellow being chosen for dessert, and green or golden for kitchen sorts, and expert observers will notice that this excludes many of our best flavoured fruits, which being russety or of a nondescript appearance, do not sell on the market boards, though where quality is asked for they cannot long remain unknown. We may look also to improved methods of packing to secure higher prices. Instead of the half-sieve (four gallons) and the sieve baskets, choice fruits should be boxed and placed in punnets and suitable packages, so that on reaching their destination they need not be again handled before reaching purchasers. Many advocate a non-returnable wooden box, such as is used for Oranges. A start has been made with ripe Gooseberries, White Currants, and Raspberries in punnets, and good prices result. The best Strawberries are of course marketed in ½ lb. and 1 lb. reputed punnets. I think also that the use of artificial manures suitable for special soils and crops must engage the attention of growers in the future. It is evident, from the use of kainit, soot, fish guano, basic slag, and rich portable manures, that the fertility of the land must be increased and retained, while with such manures the crop of weeds which so often follows the use of stable manure may be avoided. There is another way in which growers should copy American producers, and that is by planting large bulks of one sort of either Plums, Apples, or Pears, so that day by day buyers can make sure of a supply of the same article. The wisdom of this is seen in the fact that when a retailer gets an Apple that suits his customers, and they have taken a fancy to it, the supply is often gone, and he buys another sort, which has to be tried before the public will take to it freely; whereas if a salesman were able to say "I shall have this sort for 14 days or so," the retailer could better gauge his wants and suit his customers. This also applies to Plums, and in fact to all fruits. As I have before stated, all old and worn-out orchards should be destroyed, as I feel confident that, with the vast quantity of improved sorts which the nurserymen of the present time have distributed, there will be no paying market for inferior fruit. The fruit of the future, again, must be carefully gathered, evenly sorted, well stored, and honestly packed; those men whose character is known on the market can always make the best prices, and any sharp practices in the way of mixing sorts and topping-up always recoil on the sender.

Growers, too, must look further afield for outlets, and I feel that the system of sending such huge bulks to London markets, only to be transhipped to other cities and towns, is doomed. Our largest growers pack their fruit, to suit distant markets, in baskets, barrels, or cases, as the particular market affects, and send it direct from their local stations instead of to London first, and thus make the best prices. It is obvious to all that there is neither time nor space in the large London markets to deal with the vast quantity that is sent there in busy seasons.

These remarks, however, are in no way intended to disparage London markets or London salesmen who do their very best for clients; but the course indicated will save those gluts of produce in the London market, and prevent lowest prices. London will always be well supplied, and can consume a vast quantity, but producers on either a large or small scale will find it pay best to send the best only for London sale. It is manifestly unfair to send the best only to distant markets, and the inferior to London, because the carriage is less, for it is a known fact that (as a rule) London buyers always give higher prices for picked fruit than provincial markets realise. There is a growing demand for fruit jellies, flavourings, temperance drinks, jams, preserved and bottled fruits, and further developments of these industries are to be looked for, not only in a trade sense, but in private families, as the process is now so simple with the new and improved automatic bottles. I have not touched on the culture of fruit under glass, because it is not within the scope of this paper. The most prosperous branch of this culture is no doubt the growth of Peaches and Nectarines. But we yet require more time to know what effect the maintenance and repair of the comparatively flimsy glass structures of the market growers may amount to, before we can consider the matter tested to an issue. Tomato-growing is really properly treated as a vegetable industry, though on the border land between a fruit and a vegetable.

Fruit Sales by Auction.—These sales in Kent are looked forward to with great interest by buyers and sellers. Cherries are generally sold first, on the trees, and the competition is often very keen for choice lots. They have been known to make £80 per acre, but that is an exceptional price. Plums are often included. Bush fruits and strawberries are sometimes sold by auction where the grower prefers a certain price "cash down" to the chances of market sales. All these are called soft fruit sales, and later on Pears and Apples are also sold by auction as hard fruits. In these sales the buyers are either local men who make it a trade, or London salesmen who have made contracts to supply buyers. The buyers take all risks, the sellers getting ready-money, and safe-guarding themselves by the customary rules as to damages. It is not advisable to sell fruit by auction from trees under ten years old, as naturally buyers' pickers are not so careful in gathering the fruit as the owners would be, and young trees are apt to be seriously damaged by heavy ladders being used. The growers pick young trees with step-ladders, which stand without the support of the tree itself.

The Kent System in other Counties.—My visits to various fruit centres have impressed on my mind the fact that we in Kent do not enjoy a monopoly of the best soils and situations, and it is certain that where the Kent systems of pruning and culture are faithfully carried out, there are thousands of acres of available land that could be profitably brought under fruit culture. This is demonstrated in many distant counties, where the orchards have been started with healthy young trees, the results astonishing the planters. I, as an expert, receive very fine fruit for naming from even Scotland and Ireland.

Social Aspect.—It will be conceded that the growth of fruit has had a marked effect on the health of the middle and lower classes, and has also, I believe, helped the cause of temperance. This is due honour to sanitary engineers and authorities. I claim that the health of the large towns and cities has been appreciably improved by the fact that good wholesome fruit can now be purchased at a cheap rate, a remark which covers Oranges and foreign produce also. It is admitted that the extended culture of fruit has perceptibly raised the standard of living in Kent, as among the rural population, so much can be earned by the women, girls, and boys, combined with the higher wages paid as piece-work to the fruit men who live in the county, that the villagers are better fed and clothed than they used to be. At the same time fruit-growing prevents that depletion of villages which goes on in other places, while the general prosperity of the country is increased. This is also a national matter, because the best soldiers and sailors are found in recruits reared in the rural districts. It is well known that large numbers of fruit-pickers spend the summer months in Kent, coming from London and other populous towns, who, we fear, do not always take much cash back with them, but doubtless their health is benefited by work in the open air.

Probable Profits.—Hitherto I have spoken of practical matters relating to culture and disposal of produce. Naturally some idea of the profits of this industry will be looked for, and I feel unable to give these with any approach to accuracy because the information at my disposal has been rendered to me confidentially; and to speak of some of the large returns made would be unfair without discounting these results by losses through bad years, caused by wet seasons, late spring frosts, summer blights, gales, &c. Therefore, to arrive at an estimate it is best to take three years' profits and average them, when the result will work out as follows:—

Cherry	orchards	on grass,	per acre,	£20.
Apple	"	"	"	£15.
Mixed	"	"	"	£15.

These estimates are for established orchards in full bearing, and such would probably pay the rent if used as grazing land for sheep independent of the top fruit crop.

	Per Acre.
Mixed plantations with top and bottom fruit over four years old	£20
Gooseberries alone	£25
Raspberries "	£20
Red Currants "	£12
Black " "	£15

It will be readily understood that much depends on the state and condition of the orchards, and it may be remarked that these average profits are frequently doubled and trebled, while absolute losses are comparatively rare.

The cost of establishing a grass orchard is variously estimated at £15 to £20 per acre for the first year's outlay. If on arable land (as before stated) the outlay may be recouped by vegetable crops before the land is laid down to grass. The expense of establishing a mixed plantation is placed at £30 to £40 per acre. In the latter, an earlier crop amply repays for the extra initial expense. In estimating profits, some experienced farmers consider seven years a better average, as they fear that a less term is too short, as profits are sadly discounted by such indirect causes as strikes, epidemics, cold seasons, and wet weather.

The Kent System of Tenure as between Landlord and Tenant.—The rule in Mid-Kent is for the landlord to pay for such permanent trees as the tenant elects to plant. Some landlords also further allow a sum for planting and staking. Having first arranged with the agent or steward, the tenant is bound to plant, protect, and keep in order all such permanent trees. But if the tenant makes a plantation, he furnishes all the bushes, canes, and plants necessary at his own expense, and at the expiration of the tenancy he has no claim on the landlord for his outlay. This is a simple matter, and has worked well when the tenancy is 14 years or more; but if a tenant dies, or leaves before the expiration of his lease, the bushes are valued to the incoming tenant as tenant right; or the landlord pays for them, and gets the sum from the new tenant; or should he be unable to pay, an extra rent is charged to cover the landlord's outlay. The passing of the Market Gardeners' Act, 1895, placed tenants who have planted in the past on a firmer footing, as under it the outgoing tenant can claim compensation for his outlay (before 1895); which is assessed by valuation if tenant and landlord are unable to agree as to terms.

It frequently occurs that valuers' estimates differ widely, and a third man, as arbitrator, has to be consulted. I think in all cases a proper understanding should be arrived at on entering into a tenancy, and from experience I believe nearly all landlords and agents are ready to meet the wishes of a tenant possessing capital and energy. In order, however, to guard against an unfair advantage being taken by an improving tenant, it is customary on many estates for the words "under no circumstances shall this tenancy be considered as a market garden" are inserted in most leases. In other cases where the tenant finds the trees and plants, it is not unusual for an agreement to be made whereby the tenant at the end of his term receives a capitalised sum equal to several years' purchase on the increased letting value of the holdings, as then determined by agreement or valuation. In my opinion the Act would have been improved if a definite number of years had been fixed under which compensation could be claimed, as bush fruits are practically useless after 10 to 15 years, Plums begin to decline after 25 years, and Apples after 60 years; but under a 14 years' lease a tenant should have reaped his profit on all outlay except perhaps on a Cherry orchard. Undoubtedly the best plan is for the tenant to be a freeholder.

Cider.—As already stated, in olden days cider was largely made in Kent, and most old farmhouses had a cider press, but beer has now almost entirely taken its place as a local beverage. Your Society has already had a paper from Mr. C. Radcliffe Cooke, M.P. for Hereford, and I need not further allude to the subject, except incidentally, to mention that during the past few years it has been taken up by a Society in the Swanley district of Kent, which commands a ready sále; but they obtain some of their fruit from Somersetshire and Herefordshire, although, on the other hand, many tons of fruit find their way from Brenchley and Paddock-wood orchards to the Norfolk cidermakers, who certainly turn out a beverage that is refreshing and agreeable to those who are not born in a cider country, and who do not know the crucial points of excellence. Cider-making undoubtedly helps the prices of Kentish Apples, and a large bulk of good sorts, but not of a size quite up to market sale, being sold for cider, relieves the London markets. The Hereford makers, however, maintain that unless special "vintage" fruit is mixed with our Kent Apples the cider does not keep, because of the absence of tannin.

To indicate the interest taken in fruit culture by cottagers and small holders of land, no less than 50,000 lists of fruits in leaflet form with hints for culture have been sold by the Royal Horticultural Society, and a new edition is now issued and sold cheaply to county councils, the clergy, &c.

DISTANCES TO PLANT.

Orchard trees, standard Apples, Cherries, Pears, or Plums in orchards should be planted about 15 to 30 feet apart, and must be well staked and protected from rabbits and stock.

Number of Market Trees required per Acre: –

1,210 at 6 ft. apart – Closely pruned Pears on quince, or Apples on paradise, and for Gooseberries and Currants.

---

* Extracts from a paper by Mr. George Bunyard, Vice-President of the Fruit Committee of the Royal Horticultural Society, read before the Members of the Society of Arts on Wednesday, May 10, 1899, Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., in the chair.

680 at 8 ft. apart—Apples on paradise (every other one to be moved in a few years).
435 at 10 ft. apart—Feathered Apples or Plums.
303 at 12 ft. apart—Permanent bush trees, pyramids, and nuts.
193 at 15 ft. apart—Standard Plums, Damsons, or red Cherries.
134 at 18 ft. apart—ditto.
108 at 20 ft. apart—Standard Apples, Pears, &c.
75 at 24 ft. apart—Ditto and Cherries.
48 at 30 ft. apart—Cherries where pastured underneath.
40 at 36 ft. apart—Cherries or Apples.
36 at 40 ft. apart—Cherries or strong Pears.

In plantations where there is both a top and bottom crop the standards may be placed at greater distances, noting that the Apples and Pears give a heavier shade than Plums.

Strawberries for market (about) at 1½ ft., 19,350; at 2 ft. 11,000 per acre.

LIST OF BEST PAYING MARKET FRUITS.

Apples.

Those marked * are recommended for orchard standards, the rest as plantation bushes or pyramids on paradise stocks.

† These are suitable for either purpose.

Dessert Apples to sell direct from the tree:

†Mr. Gladstone	July-August
†Beauty of Bath	,, ,,
Yellow Ingestre, or Summer Golden Pippin	September
†Devonshire Quarrenden	August
†Colonel Vaughan	Sept.-Oct.
Lady Sudeley	Aug.-Sept.
†Worcester Pearmain	September

Dessert Apples which require to be stored for a time before Marketing.

†Duchess Favourite (or Duchess of Gloucester).	Sept.-Oct.
†King of Pippins	Oct.-Jan.
†Cox's Orange Pippin	Nov.-Jan.
†Gascoyne's Scarlet Seedling	Nov.-Feb.
†Cox's Pomona	Oct.-Nov.
†Baumann's Winter Reinette	Dec.-Jan.
†Cockle's Pippin	Oct.-Nov.
†Allington Pippin	Nov.-Feb.
*Duke of Devonshire	March-May

Kitchen Apples which require storing before Marketing.

†Stone's, or Loddington	Aug.-Dec.
†Warner's King	November
†Lord Derby	Nov.-Dec.
*Queen Caroline (or Brown's Codlin)	Oct.-Dec.
*Tower of Glamis	Oct.-Dec.
*Wellington	Nov.-Mar.
*Winter Queening	Dec.-Feb.
†Bismarck	Oct.-Jan.
*Newton Wonder	Nov.-May
†Graham's Jubilee	Oct.-Mar.
*Bramley's Seedling	Dec.-April
*Golden Noble	Nov.-Dec.
Lane's Prince Albert	Nov.-April
*Hambledon Deux Ans	Mar.-May
Northern Greening	Jan.-Mar.
*Hambling's Seedling	Dec.-Mar.
*Alfriston	Nov.-Mar.

The following make grand trees and bear regularly when about 20 years old. A proportion should be placed in every grass orchard:—

Blenheim Orange	Nov.-Feb.
Kent Fillbasket	November
Striped Beefing	Nov.-Feb.
Mère de Ménage	Dec.-Jan.

Kitchen Apples to market direct from the tree.

†Early White Transparent	July-Aug.
*Early Julian	Aug.-Sept.
†Potts' Seedling	,, ,,
†Lord Grosvenor	,, ,,
†Lord Suffield	,, ,,
†Keswick Codlin	,, ,,
†Early Rivers'	,, ,,
†Domino	,, ,,
†Duchess of Oldenburg	,, ,,
†Ecklinville Seedling	Sept.-Oct.
†Grenadier Codling	,, ,,
Manks Codlin	,, ,,
†Golden Spire	Oct.-Dec.
Stirling Castle	Oct.-Nov.
†New Hawthornden	Nov.-Dec

The softer kinds of Apples are best for local sales as they bruise in transit to distant markets.

Pears.

Market Pears for Orchard Trees.

Hessle	September
Crawford, or Chalk	August
Jargonelle	,,
Williams' Bon Chrétien	September
Dr. Jules Guyot	,,
Pitmaston Duchess	Oct.-Nov.
Fertility	September
Beurré Bosc	Oct.-Nov.
Beurré Capiaumont	Sept.-Oct.
Catillac (for stewing)	Dec.-Mar.
Vicar of Winkfield	Dec.-Jan.

Pears as bush trees on quince stock.

Beacon (Rivers')	August
Williams' Bon Chrétien	September
Dr. Jules Guyot	September
Souvenir de Congrès	,,
Conference	October
Marguerite Marillat	,,
Louise Bonne of Jersey	,,
Pitmaston Duchess	Oct.-Nov.
Marie Louise d'Uccle	,, ,,
Beurré Clairgeau	,, ,,
Emile d'Heyst	,, ,,
Durondeau	,, ,,
Princess	,, ,,
Beurré Jean van Geert	November
Fondant de Thirriott	Nov.-Dec.
Doyenné du Comice	Nov.-Dec.

The list mentioned on Quince stock can also be grown as standards where the soil is suitable for Pears, and many other kinds grown in gardens can be introduced to meet any special local demand.

Plums.

Profitable Market Plums, either as standards in orchards or as half-standards and bushes in plantations.

Rivers' Early Prolific	July-Aug.
Czar (Rivers')	August
Heron (Rivers')	,,
Early Orleans and Prince of Wales	,,

(Only in places where they succeed.)

Belgian Purple	September
Belle de Louvain	,,
Black Diamond	,,
Curlew (Rivers')	,,
Jefferson's Gage	,,
Smith's Blue Prolific	,,
Bush Plum of Kent	,,
White Magnum Bonum	,,
Oullin's Golden Gage	August
Pond's Seedling	September
Victoria or Royal Dauphin	August
Sultan	,,
Early Transparent Gage	September
Wyedale	Oct.-Nov.
Monarch	Sept.-Oct.

Green Gages require a favourable situation. The best are—

Denniston's Gage	August
Early Transparent	September
Bryanston's Late Gage	,,
Late Transparent	,,
Jefferson's	,,
Old Green Gage	August
Cambridge Gage	September
Coe's Golden Drop (late)	Sept.-Oct.

Damsons.

Bradley's King. Hereford Prune. Frogmore (large).
Shropshire. Farleigh Prolific, or Crittenden.

The above Damsons are in fruit in September and October. Useful to shelter plantations on the exposed portions.

Cherries.

For Orchard Standards. (It is useless to plant less than an acre, as they do not pay to look after, scare birds, &c., on a less area.)

White and Amber Hearts.

Frogmore Early	Early
Elton Heart	Early
Kent Bigarreau	Medium
Napoleon Bigarreau	Late
Florence Bigarreau	Late
Emperor Francis	Late
Ludwig's Bigarreau	Early

Red Sorts.

Kentish—Medium. Flemish—Late. Morello—Late.

These can be used as standards or bushes.

Black Hearts.

Old Black Heart	Early
Black Eagle	Medium
Early Rivers'	First Early
Cluster or Caronne	Late
Werder's Black	Early
Waterloo	Medium
Black Tartarian	Late

Bush Fruits.

Currants—Black Naples, Baldwin's Black, Lee's Prolific (black), New Red Dutch, Raby Castle (red).

Raspberries.—Norwich Wonder, Bunyard's Superlative.

Gooseberries.—Lancashire Lad, Whinham's Industry, Red Warrington, Crown Bob, Keepsake, Rifleman.

Strawberries.—Royal Sovereign (early), Eleanor (late), Sir J. Paxton, President, and Laxton's Monarch, for local sale where they succeed. British Queen, Latest of All, and Dr. Hogg.

Mr. W. W. **Berry** said it had given him great pleasure to listen to this paper, and he might say that on this subject Mr. Bunyard was a prophet, not without honour, even in his own country, and the tenant farmers and landlords of Kent would always be grateful to him for the pioneer work he had done, for the advice he had given, and for the indomitable perseverance with which he had carried out his experiments over many years. The question of selection and packing of fruit was all-important. If he had 100 bushels of Apples from a tree, he would rather send 60 per cent. of the best, even if he had to throw away the other 40 per cent., but that was not at all necessary. If you picked out the very best, say 20 per cent., and packed them carefully in boxes, and then took a further 40 or 50 per cent. and packed them carefully in baskets, the returns from those two sections would be greater than from the whole 100 bushels marketed in a careless way; there would be a saving in carriage, in packing, and in other ways, and you would still have 30 to 40 per cent. of sound fruit to deal with, which you could dispose of to the "smasher," as the jam maker or cider maker was termed, at a fairly remunerative price. The same thing would apply to every kind of fruit. Another improvement was the steam cultivation of the land, not only in clearing old woodlands, but even on some of the best land in Kent, where he would not think of planting fruit trees without first thoroughly ploughing it and stirring the subsoil by steam. He recently broke up 14 acres, first ploughing it 9 to 12 inches deep by steam, and then following the burrows with a powerful steel implement to break up the soil underneath, being careful not to bring the subsoil to the top, but thoroughly breaking it up from 21 to 24 inches deep. The whole cost was not more than £2 per acre, if you hired the implements, and that was quite saved in the cost of planting. Artificial manure was another important point. Any farmer or fruit-grower could now be supplied with exactly the manure his land or crop required, and at a moderate price—either prepared bones, guano, or some of the phosphatic manures which had been referred to. One of the principal reasons for which he would recommend these things in preference to farm-yard manure, was the economy in application. Apart from the question of weeds, which was very serious, especially with manure from London, the expense of hauling 20 or 25 tons of farm-yard manure on to an acre of fruit land, getting it to the plantation, and then getting it out and in amongst the fruit bushes, was enormous; whereas if you had a suitably-prepared manure, with the proper quantity of potash, phosphates, and ammonia, it would all go in a one-horse cart and be carried out and sown broadcast on the land for three or four shillings. On a large scale that saving alone would make a good living for the fruit grower. With regard to foreign competition, there had been complaints for 25 years, but he thought the time had come to admit that the British fruit-grower was largely dependent on the foreign and colonial produce. In the old days a small quantity of fruit could be sold during the season; there was a shop here and there, and fruit was very dear, and when any unusually large quantity was sent to market, there was no one to distribute it. The season then only lasted three or four months, but now we had choice fruit all the year round. There were hundreds of shops, stores, and barrows—fruit was constantly put before the public, who were thus educated to the consumption of it, and insisted on having it, and thus the fruit-grower was far better off than he would have been without the foreign supplies. Reference had been made to the advantage of fruit and Hop growing in keeping labourers on the soil, which was a matter in which he took great interest. Things were looking up a little in every branch of agriculture, and they wanted more labourers than they did a few years ago, but they could not get them. They were often in great straits for men to do a little extra work which they knew would pay for doing. If you went away from the most prosperous districts, up into the hilly and barren parts, you would find only one in three, or one in six of the cottages occupied, but down where fruit and Hops were grown, and near the towns, there was an enormous dearth of labour. Instead of getting the assistance they used to have from the hill country, when there was any extra work, they could not now find it. In the villages where fruit-growing was carried on, there was work during the winter in pruning, manuring, digging, making new plantations, and so on, and he was paying £1,000 in wages now, where £100 was paid when he was young; and a house could not be got for love or money, though five miles away there were empty houses, because there was no work for the men to do. The fruit industry, therefore, was a grand thing, and it must be the same in many other counties. Fruit was becoming more and more popular every day; it had never been overdone yet, except in one year, 1886, when there was the biggest all-round crop of fruit ever known, and at that time the system of distribution had not developed in proportion. There might be a crop now three times as big as that, and it would all go to market, and the public would get the benefit of it. Enormous quantities of hothouse Grapes and Tomatos were now produced in this country. Mr. George Munro had given evidence before a Parliamentary Committee that in one year he had sold 700 tons of English-grown hothouse Grapes, in addition to those from the Channel Islands, and more than 1,000 tons of Tomatos.

Mr. J. **Assbee** said it was perfectly true, as the last speaker had said, that it was much better to keep inferior fruit out of the market altogether, than to put it in with the better class. He had repeatedly seen the sale of good Apples entirely spoiled because certain growers thought that they could get the better of the public by putting inferior ones in with them. There were two distinct classes of buyers: the man who bought the best and gave the best prices, and the man who bought the worst and only paid the lowest price. If you sent a mixed lot, the good man would not look at it, and consequently the lower-class buyer must have it, and he would only take it at his own price, and thus the grower often did not realise the cost of carriage, simply through carelessness and stupidity in packing his goods. Foreign competition in fruit was like foreign competition in everything else—cereals, hay, straw, eggs, butter, cheese, or poultry. Foreign fruit could not be kept out of the market, and it answered a very useful purpose. No doubt, it had stimulated the public taste for fruit; the more fruit people ate, the more they liked it. He had often wondered what our forefathers did for fruit; the people, generally, could have had hardly any. He could remember the time when the only thing you could get in winter was an Orange. The colonies were making great strides in this direction. Cape Colony had recently come to the fore, and within a decade would be sending fruit here which would be a surprise to many people. But it would come in when the English fruit was over. English Grapes were now just finished, and there would be a good opening for Grapes from the Cape. They had a few this year, but nothing to what would be sent in a year or two. It was the same with Apples, which were just beginning to arrive. Men had gone to the Cape from California, who were laying down hundreds of acres of land in fruit, and they would be sending thousands of packages before many years. But it would do no harm to English fruit, which was equal to anything in the world when well grown and properly sent to market.

Mr. George Gordon, V.M.H., said the course advocated by Mr. Berry of cultivating the land for fruit-growing by steam, was much better than what was described in the paper as the usual plan in Kent, namely, making holes, planting the trees, and keeping the surrounding space free from grass and weeds. It was much better to thoroughly pulverise the whole soil, so as to allow of the free growth of the roots. A cultivated orchard was preferable to a grass orchard, though it might not be necessary to do more than horse-hoe it once or twice in a season, so as to maintain a loose surface and prevent cracking. It was quite open to discussion whether even Cherry orchards should not be dealt with in this way, with crops and bush fruit between the trees. For some years he had been watching a Cherry orchard formed in this way. At first it was simply kept clean, and after a year or two it seemed quite at a standstill. Then the whole ground was trenched by hand, and the results were marvellous. The trees were planted eight years ago, and now they had heads of from 12 to 15 feet in diameter, and a few days since they were literally one mass of flowers. The question of packing was very important. The Normandy growers sent over large quantities of Plums packed in small boxes, holding from 6 to 12 lbs. The fruit came over in splendid condition, and the consumer could buy a box and take it home without any disturbance, and use the fruit as required. When Plums were sent to market in sieves, they got shaken considerably on the journey; then when the retailer got them up home, he turned them out on to the counter, shovelled them up into the scale, turned them out again into a paper-bag or basket, and by the time they reach the customer's house they had been so knocked about that unless used immediately they would be spoiled. He was sometimes told that the cost of boxes was prohibitive, but that could hardly be so, seeing that the Great Eastern Railway Company supplied boxes at from ½d. to 5d., the larger ones being big enough to hold 60 lbs. At any rate, the choicer kinds of fruit should be packed in this way. The renovation of old orchards was another point of importance, but they need not always be destroyed; he had seen orchards which seemed going to decay by proper care brought into a highly fruitful condition. He knew a gentleman who had an orchard consisting chiefly of Blenheim Orange which were said to be quite worn out, but by opening out a space between the rows, trenching, and supplying with farmyard and artificial manure, the trees took a new lease of life, and were now vigorous and fruitful.

Mr. E. D. Till thanked Sir Owen Burne for his remarks on Mr. Bunyard's reference to cider-making, and he remembered that when Mr. Radcliffe-Cooke read a paper on cider before the Society, the Chairman, Sir W. T. Thiselton-Dyer, was also sympathetic on the same subject. He would like to state his own experience. In 1895 there was an abnormal crop of Apples in Kent, and he urged the Technical Education Committee of the Kent County Council to make experiments with a view to instructing Kentish people as to cider-making. They declined, but as a glut crop is not too frequent, he urged two Scotchmen, farmers at Swanley, to get an expert from Hereford, erect a press, and as Apples were plentiful they made 5,000 gallons that season. In a "glut" year liquid storage is the best way of saving a crop and relieving a glutted market of fruit. Something like 40,000 gallons have been made at Swanley since that experiment, and it is commercially successful. There is no difficulty in selling it. It contains a low percentage of alcohol, 2½ and 3 per cent., and although cider from Kent fruit is different in character from that of the West country, it is not deficient in fine quality and flavour. As to keeping properties, he had been lately drinking good cider, made in 1895-1896 from local fruit. In the Weald of Kent they have lost the true art of cider-making; they put sugar in it, which is a great mistake. The French were paying more and more attention to the manufacture of cider. Mr. Radcliffe Cooke had said he knew nothing for agriculturists which offered such an unlimited and profitable field as cider-making. Mr. Cooke's advocacy of cider, and specially in the interests of his own county, Hereford, had led to his being called the "great De-*cider*-atum." He would like to say that Mr. Bunyard had not referred to poultry keeping in orchards, but he thought it was a valuable and profitable adjunct, and he might mention that the production of poultry and eggs now was equal in value to the value of our wheat crop, and still admitted of immense extension.

Mr. D. Louis said the washing of fruit trees with poisonous materials had been practised for the last 50 years, and it was constantly done in France and elsewhere, as well as in England. He did not know of any recorded case in which any accident had arisen therefrom. In connection with artificial manures, he was pleased to hear Mr. Berry's remarks; he had been advocating it in Kent for some years, both because it was more efficient, and on account of the saving in carriage. But these things were adjuncts, not substitutes entirely for farmyard manure, and it was necessary that the right material should be applied at the right time and in the right way, otherwise it might be injurious. He lately had an interesting example of that on some thin soil in South Kent, just over the chalk. It had been dressed persistently with superphosphate, with very bad results; but when he saw the character of the vegetation he recognised that the soil was acid, and advised the use of basic phosphate. That was put down, and the result was an entire change in the appearance of the place.

Mr. Bunyard, in reply, said he strongly recommended that all new orchards should be raised on arable land, except for Cherries, for which he could not advise that course. It was true they did well under it, but if there came a severe frost—anything below 24° below freezing—the trees would be completely spoiled; and not only that, but where the ground was very well manured, the Cherry-trees ran away altogether. He was called in to advise at a place in Gloucestershire, where they had manured the trees highly, and they made enormous growth, 6 feet in a year, but when they got a hard frost, the trees were completely spoiled. To farm a good Cherry orchard, you must let it go on very slowly. With regard to renovation, if you had good sorts, by all means go in for it, but it was useless to take the trouble if the sort of fruit was not good enough to pay for it. With regard to spraying, he had to be very careful what he said. If he advised people to do this, it might be done carelessly, and very grave results might ensue. He knew of a case where a man washed his Apple trees with London Purple, and some of it fell on the Gooseberries, resulting in a vast amount of illness. It was a good thing to use where people were sufficiently careful. A man once said to him, "I never tell people to do it, but I do it myself;" and that was sometimes his position.

The term "accumulated temperature indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. *Principal Wheat-producing Districts*—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S.

Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 20, is furnished from the Meteorological Office:—

"The *weather* during this period was very unsettled and rainy generally, especially in the west and north. Thunderstorms were experienced in many parts of the Kingdom soon after the commencement of the week, and, again in some districts later on.

"The *temperature* was rather below the mean in Scotland, Ireland, and the south-west of England, and just equal to the normal in 'England, N.W.,' but in all the other English districts it was a little above it. The highest of the maxima occurred on the 18th over England, and on somewhat irregular dates in Ireland and Scotland; they ranged from 72° in 'England, S.' (in London), and 71° in 'England, E.,' to 62° over Ireland, and 60° over Scotland. The lowest of the minima, which were registered on different days in the various districts, ranged from 31° in 'Scotland, E.,' and 33° in 'Scotland, W.' and over Ireland, to 43° in 'England, S.,' and to in the 'Channel Islands.'

"The *rainfall* exceeded the mean in all districts. The aggregate fall was very heavy generally, varying from about twice as much as the normal over northern, central, and southern England, to about three times as much in most western and northern districts and in 'England, E.,' and to four times as much in the west and east of Scotland.

"The *bright sunshine* was deficient in all parts of the Kingdom. The percentage of the possible duration ranged from 41° in the 'Channel Islands,' 37 in 'Ireland, S.,' and 34 in 'England, E. and S.W.,' to 21 in 'England, N.E.,' and 15 in 'Scotland, N.'

MARKETS.

COVENT GARDEN, MAY 25.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Potatos.

Bruce, Saxon, and Main Crop, 80s. to 100s.; Up-to-Date, 95s. to 105s.; Dunbar Main Crop, 100s. to 110s. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

Remarks.—In last report Peaches should have read 6s. to 24s. per doz. (not 42s.). Radishes and Spinach are now coming fast, and both are very much down in price. Pines are rather short supply, and nothing very fine. Apricots vary in price, the larger the fruit the higher the price. The foreign Cherries to-day were very good. Asparagus is plentiful, and in great variety, English and foreign, and prices are low.

Vegetables.—Average Wholesale Prices.

SEEDS.

London: *May* 24.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., describe to-day's market as quite of a holiday character, with scarcely any business passing. Quotations all round are consequently without any alteration. Small orders still drop in for Tares Rye continues scarce. Canary-seed, with more doing, tends upwards in value. Hemp-seed keeps very firm. Mustard and Rape are steady. Peas and Haricots command full rates.

CORN.

Average Prices of British Corn (per imperial qr.), for the week ending May 20, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.	1899.	Difference.
	s. d.	s. d.	s. d.
Wheat	48 1	25 3	– 22 10
Barley	26 0	23 11	– 2 1
Oats	21 3	17 10	– 3 5

FRUIT AND VEGETABLES.

Glasgow: *May* 24.—The following are the averages of the prices recorded since our last report:—Apples, Canadian Spies, 14*s*. to 18*s*. per barrel; Western States' Russets, 18*s*. to 20*s*. do.; Oranges, 6*d*. to 1*s*. per dozen; Grapes, home, 2*s*. to 4*s*. 6*d*. per lb.; Tomatos, Guernsey, 4*d*. to 8*d*. per lb.; do., Scotch, 5*d*. to 8*d*. do.; Cabbages, Spring, 6*d*. to 1*s*. per dozen; Broccoli, Edinburgh and Irish, 2*s*. to 2*s*. 6*d* per dozen; Herbs, assorted, 1*d*. to 2*d*. per bunch; Leeks, 1*s*. to 3*s*. per dozen bunches; Mint, green, 6*d*. per bunch; Onions, 4*s*. 6*d*. to 5*s*. per cwt.; Parsley, 1*s*. 6*d*. to 2*s*. per stone; Carrots, round, new, 1*s*. per bunch, and 4*s*. 6*d*. to 7*s*. per cwt. (old); Cucumbers, 4*d*. to 5*d*. each; Lettuces, round, 1*s*. 3*d*. to 1*s*. 6*d*. per dozen; Horseradish, 1*s*. 6*d*. to 2*s*. per bundle; Mushrooms, 1*s*. to 1*s*. 3*d*. per lb.; Beetroots, 6*d*. to 7*d*. per dozen; Mustard and Cress, 3*d*. per punnet; Spinach, 2*s*. to 4*s*. per stone; Turnips, French, new, 1*s*. to 1*s*. 3*d*. per bunch; Swedes, 2*s*. to 2*s*. 6*d*. per bag; Greens, 9*s*. to 6*s*. per 10 dozen.

Liverpool: *May* 24. — *Wholesale Vegetable Market.* — Potatos, per cwt., Main Crop, 3*s*. 9*d*. to 4*s*. 6*d*.; Bruce, 2*s*. 10*d*. to 3*s*. 6*d*.; Champion, 2*s*. 9*d*. to 3*s*. 3*d*.; Turnips, Swedes, 3*s*. 6*d*. do.; Carrots, 5*s*. 6*d*. to 6*s*. 6*d*. do.; Parsley, 6*d*. to 8*d*. per dozen bunches; Onions, foreign, 4*s*. to 5*s*. per cwt.; Cucumbers, 1*s*. 3*d*. to 3*s*. per dozen; Broccoli, 10*d*. to 2*s*. per dozen; Cut Cabbages, 6*d*. to 10*d*. do. *St. John's.*—Potatos, 1*s*. to 1*s*. 2*d*. per peck; do., new, 2*d*. to 4*d*. per lb.; Grapes, home, 2*s*. 6*d*. to 4*s*. do.; Pines, English, 4*s*. to 6*s*. each; Strawberries, 4*s*. per lb.; Gooseberries, 6*d*. per quart; Peas, 3*d*. per lb.; Cherries, 6*d*. to 1*s*. do.; Cob Nuts, 8*d*. do.; Apricots, 1*s*. per dozen; Asparagus, 2*s*. to 4*s*. per 100; do., bundle, 1*s*. 6*d*. to 3*s*.; Cucumbers, 3*d*. to 4*d*. each; Mushrooms, 1*s*. 3*d*. per pound and basket. *Birkenhead.*—Potatos, 1*s*. to 1*s*. 2*d*. per peck; do., new, 3*d*. to 4*d*. per lb.; Peas, 5*d*. to 8*d*. do.; Asparagus, 2*s*. to 4*s*. per 100; Cucumbers, 2*d*. to 4*d*. each; Strawberries, 8*d*. to 2*s*. per lb.; Cherries, 6*d*. to 8*d*. do.; Apricots, 1*s*. per dozen; Gooseberries, 6*d*. per lb.; Grapes, home, 3*s*. 6*d*. to 4*s*. 6*d*. do.; Mushrooms, 1*s*. to 1*s*. 6*d*. do.

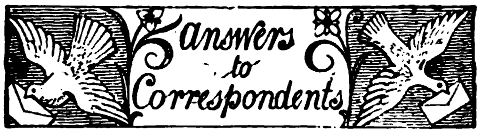
GARDENING APPOINTMENTS.

Mr. A. Baker, late Foreman at Highfield Gardens, Shoreham, Kent, as Gardener to H. H. Hett, Esq., Hapstead House, Ardingly, Sussex.

Mr. T. Randall, for the last nine years Head Gardener at Holme Lacy, Herefordshire, as Head Gardener to A. Boughton Knight, Esq., Downton Castle, near Ludlow.



Answers to Correspondents

Address: *A Twenty Years' Reader of the Gardeners' Chronicle.* We think that the person whose address you require is to be found at Green Lanes, Stoke Newington, London, N.—*W. H. K.* The address asked for is Mr. B. Wynne, 1, Danes Inn, Strand, London, W.C.

Adhesive Shading: *Veritas.* The horticultural sundriesmen keep several such preparations of about equal goodness.

Cucumber Plants Failing: *S. B.* The roots are infested with eel-worms against which nothing can be done to rid to plants of them. The worms are introduced with the soil, which, owing to not having been stacked for a year or two, and kept clear of herbage, swarms with them. Clear out the soil and plants, and start anew. Bake the soil before using it.

Cucumbers Yellow, and Decaying at the Ends of the Fruits: *A. C.* In the absence of information in regard to treatment, we should attribute the decay to lack of bottom heat. There are no signs of eel-worms on the roots sent.

Double Mushroom: *W. S.* A common occurrence.

Evergreens for Planting on a Steep, Dry, Sandy Bank: *E. P.* You might make your choice of any of the following:—Furze, double or single-flowered; Common Broom, Tamarisk, Mahonia aquifolia, Common Juniper, also Juniperus Sabina and J. tamariscifolia; Abies Clanbrassiliensis, Scots and Black Austrian Pine, Pinus Pinea, Butchers' Broom, Olearia Haasti. At the bottom of the bank, the Periwinkles, Ivies, and Euonymus would succeed.

Grapes Diseased: *St. Clair.* The berries are infected by Glæosporium læticolor—the "Spot" fungus. Cut off and burn every affected berry, and then apply sulphur by various methods, or use sulphide of potassium, half an ounce in a gallon of water. The bunches would have to be syringed with clear water before eating them.

Ivy-leaved Pelargoniums: *C. P. & Co.* The leaves were pierced by aphis, whilst very young, which has given them a crippled appearance. No fungus.

Lily Flower Buds: *A. C.* The yellowing is due to a check, but how caused we are unable to say.

Melon and Cucumber Roots: *K. M. W. and W. G. S.* The roots are badly attacked with eel-worm. Turn out the soil and get fresh loam, taking the precaution to bake it before using.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—J. T. L.* 1, Dendrobium Bensoniæ; 2, Dendrobium Parishi.—*R. K.* A very fine variety of Odontoglossum triumphans, of that uncommon type having a white ground colour to the petals and lip.—*J. K., Melton.* 1, Dendrobium aggregatum; 2, D. Dalhousieanum; 3, D. chrysotoxum; 4, Saccolabium ampullaceum; 5, Clematis; 6, Sprekelia formosissima; 7, Davallia dissecta Mariesii; 8, D. Mooreana; 9, Adiantum trapeziforme; 10, A. formosum; 11, Gymnogramma ochracea; 12, Selaginella viticulosa. Another time send six only. A contribution to the Gardeners' Orphan Fund would be welcome.—*E. S. J. T.* Miltonia flavescens, formerly called Cyrtochilum stellatum.—*J. M.* 1, Nothochlæna trichomanoides; 2, Pellea (Platyloma) flexuosa; 3, Pteris hastata; 4, Davallia tenuifolia stricta; 5, Polystichum angulare; 6, Ixia crateroides. — *C. G.* 1, Lonicera tatarica; 2, Diervilla florida *syn.* Weigela rosea.—*J. T. L.* Savin, Juniperus Sabina var.—*M. Neath.* 1, Dendrobium Hildebrandi; 2, D. Devonianum; 3, D. chrysotoxum.—*G. E. S.* Ceanothus rigidus. —*F. C.* Claytonia perfoliata.—*Subscriber* (*Brown*). Prunus Padus, the Bird Cherry.

Odontoglossum cirrosum: *M. Neath.* The flower-spikes when produced in the winter, and under conditions not favourable to the quick development of the flowers, often go in the manner shown in the specimen sent. The plants are not at fault. Probably, a rather cooler temperature would be beneficial.

Orchid Collector: *D. L.* The course most likely to be attended with success would be to offer your services, together with testimonials as to knowledge and ability, &c., to some Orchid-importing firm in this country or in Belgium. This might be done by means of advertisement or letter.

Spanish Iris and Jonquils not Flowering: *Dun, Leamington.* Assuming that the bulbs in each case are healthy, their failure to bloom is probably due to immature growth, untimely loss of foliage, enormous reproduction, or to deep planting. Both require a well-drained soil, of good depth, and an open, sunny situation. We would advise the lifting of the bulbs as soon as, in the case of the Jonquills the foliage turns brown, and the Iris in the middle of the month of August. They may have grown so rapidly, and formed such large masses of bulbs, that the soil around them is practically exhausted, and growth is in consequence much weakened. Having prepared new stations for them, replant the stronger bulbs at 3 to 4 inches apart and 3 inches deep, in colonies of thirty to fifty, or in beds, the ground being made quite firm both before and after planting. The weaker bulbs may be put in nursery lines to grow strong before planting them in the beds or borders.

Strawberry-flowers Failing to Set: *J. W.* You will do well to acquire a fresh stock of plants. Strawberries occasionally evidence a tendency to revert to a diœcious condition, and fertilisation is then much less easy or certain than in the case of plants bearing hermaphrodite flowers.

Tomatos: *G. T. R.* The fruits are attacked by a fungus (Cladosporium locopersici). Preventive methods such as syringings with sulphide of potassium or Bordeaux Mixture, when adopted early in the season are generally productive of good, but if your plants are now bearing a crop, all you can do will be to remove, at once, every fruit that shows evidence of disease.

Vine: *D. B.* The Vine-leaves sent are affected with the malady called "Browning," *Brunissure* of the French. There is no known cure, and only timely prevention is of any use, which is found in occasionally syringing the leaves with the Bordeaux Mixture (see answer to correspondent last week), or by using sulphide of potassium, at the rate of half an ounce in a gallon of water.

Gardeners' Chronicle
No. 649.—*SATURDAY, JUNE* 3, 1899.

PREPARING FOR THE SHOW.

THE work entailed in preparing for a great show is very considerable, a great many subjects having to be selected for growing on as much as a year previous to the exhibition. Having selected the most promising plants, the work and worry begin, and there must be no relaxation of care and watchfulness until the plants are finally arranged in the show tents.

Preparing.—The primary work is to get the flowering plants well set with buds, and to work up such hardy plants as Deutzias, Philadelphus, Azaleas, and other subjects of a like nature. To have them in flower to a day is a work requiring great care and judgment, and quite 20 per cent. of those selected to be grown have to be discarded; some being too early, others too late, so much depending on the season and the amount of sunshine the plants receive. These subjects have to be moved from one house to another, either to retard them if too forward, or to push them on should they require it. Again, some kinds of plants come into bloom much more rapidly than others, and consequently several glass-houses with a variety of temperatures are necessary to get all in perfection at the same time.

To grow and show a collection of Cacti is a feat of skill in itself, as most horticulturists know. To have a large number of plants in bloom on a certain date, means a great amount of skilful manipulation; if the flowers open too soon or if they are a day too late, a year's labour in many cases is lost. The same may be said of other flowering subjects, such as Gloxinias, Lilies, and many others.

Packing.—The work of preparing and growing the plants is but one item of the expense involved in exhibiting plants, for these would be of no use if great care were not exercised in packing them so as to travel safely to the show. The packing in itself is a special business, for this must not only be done with expedition, but great care must also be exercised. Choice Orchids require, in some instances, that each flower must be carefully tied up in paper and protected with cotton-wool and others with long sprays must have supports formed of cotton-wool and light sticks, and the whole plant afterwards enveloped in paper so that no particle of dust may settle upon the flower to mar its pristine beauty. The same remarks apply to other flowers that are easily bruised. Caladiums and other fine foliaged plants with tender leaves require quite as much, if not more, care and labour in packing, as each leaf must be supported and carefully protected from injury whilst in transit, as the least bruise or puncture of the leaves spoils the beauty of the plant.

Hardy plants that have been forced into flower, and those grown in the open, are placed in baskets, which look best when covered with green baize; and each individual plant must be carefully tied, to prevent the flowers rubbing each other, and some plants that have delicate flowers also require wrapping in paper. After each plant has been carefully tied and papered, they are then packed in covered vans with light springs, specially constructed for the purpose, some of which are heated when the plants have to travel far and the weather is cold.

Setting-up.—The work of selection, growing, and packing being completed, there is still a lot of hard work to do; each plant has to be unloaded, and very often carried a long distance to the place allotted for it in the exhibition. The plants have to be untied, and then placed in their various groups, which occupies a considerable amount of time, and requires a great amount of patience; for it often happens that when an exhibitor has set up his group it does not please him, and certain plants have to change places—some have to be raised, and others lowered, and so on, until the appearance of the whole is satisfactory.

The setting up of the plants being finished, there is still more work to do, for the packing material must be gathered up and stowed away out of sight, and all the litter made in unpacking must be cleaned up before the time for judging the exhibits arrives.

Removal.—We scarcely need to remind the reader that all the plants brought to a show ought to be repacked with as much care for their removal as was bestowed on them when being prepared for exhibition.

To bring together the innumerable subjects to form so grand a display as that seen in the Temple Gardens annually, gives employment to quite an army of workers, not only during the time of the show, but also year in and year out. The amount of thought and skill employed is incalculable, and the amount of money spent annually, we are persuaded, would amount to a goodly fortune.

[Our supplementary illustration, showing the plants in their travelling costume, was taken in Messrs. Veitch's Nursery at Combe Wood. Ed.]

ORCHID NOTES AND GLEANINGS.

CŒLOGYNE PANDURATA.

Although upwards of fifty years have elapsed since this species was first flowered in this country, it is still rarely seen, and this is the more singular because it is one of the most striking of Cœlogynes. Its habit is of a rambling nature, and for this reason the plant is best grown on a raft. The colour of the sepals and petals is bright green, and the lip, as indicated by its specific name, resembles in form a violin, and is furnished with black ridges and dots. It is a native of Sarawak in Borneo, and revels under cultivation in a hot moist atmosphere. There is a plant here at the present time bearing a spike with twelve flowers. *J. G., Botanic Gardens, Liverpool.*

Restrepia trichoglossa, *Lehmann.*

A plant of this graceful species, of small growth, is flowering in Sir Trevor Lawrence's collection at Burford, and in the Royal Botanic Gardens, Glasnevin, Dublin. Mr. Moore, the director of the Dublin garden, kindly sends a specimen for our inspection. The plant in its growth and in its flowers suggests a miniature, tufted, profuse-flowering form of R. antennifera, but an examination showed it to be distinct from that species and from all others previously recorded. The upper sepal is lanceolate, and prolonged into a tail, bearing an oblong yellow-coloured knob at the end, and the other portion is white with purple-coloured markings. The broader connate lower sepals are yellowish-white, densely spotted with crimson-purple. The petals resemble the upper sepal in form and colour, but are smaller, and the singular-looking lip, which is pressed down in the lower sepals, is of a yellow tint, spotted with crimson papillæ, and bearing on each side at the base a stout, short white, hair-like process.

Phaius × Cooksoniæ.

Some flowers of this pretty variety, sent by Mr. Wm. Murray, gr. to Norman C. Cookson, Esq. Oakwood, Wylam-on-Tyne, show that this cross between P. grandifolius and P. Humbloti (which took the Royal Horticultural Society's 1st prize for the best hybrid Orchid flowering in 1895) is worthy to be placed with the best of them. The sepals and petals are broad, and of a nankeen-yellow tint, the lips being coppery-yellow, changing to rose-colour at the tips, and the reverse is also rose-coloured. The nicely-rounded lip is of a bright yellow tint at the base with red stripes, the handsome front lobe being of a bright deep rose. These hybrid Phaius are very easy to cultivate, and very useful for decorating the dwelling-house; a stay in which does them more good than harm, as is Mr. Murray's opinion. Other varieties of Phaius, with flowers larger than P. × Cooksoniæ, have been raised at Oakwood.

Odontoglossum × crispo-Halli.

Some flowers of this beautiful variety, itself a cross between O. Halli leucoglossum ♀ and the finely-blotched O. crispum Cooksoni, and raised by N. C. Cookson, Esq., Wylam, and now sent by him, show improvement upon those first exhibited at the Royal Horticultural Society, November 24, 1896, beautiful though those were which obtained a First-class Certificate. As yet, at least, the production of varieties of Odontoglossum has not been an easy matter, and Mr. Cookson is justly proud of his achievement in this instance. The flowers may be said to have the size and shape of a good O. Halli, but with broader sepals and petals. The crest resembles that of O. Halli, but the processes are less prominent. The marking of the nearly white ground is rather more like that of O. crispum Cooksoni, except that some of the blotches are larger. The sepals and petals are white, with a faint yellow tinge, two-thirds of the surface of the sepals being occupied by three or four red-brown blotches; and the petals, to the extent of half their area, are covered by several smaller blotches of the same hue. The fringed lip is white, and the crest yellow and red, with one large red-brown blotch in the middle, and an even array of small ones, of the same tint up each side. The column is white on the upper side; the toothed wings and under surface are of a red tint. The spotting shows through at the back of the flower, rendering it striking in every aspect.

NATURAL GARDENING.

An interesting and instructive address on the above subject was given by Dr. Lionel Beale, F.R.S., in connection with the Weybridge Gardeners' Mutual Improvement Society, on the 10th ult. Dr. Beale, in his opening remarks, dwelt at some length on the pleasure which may be derived from this kind of gardening, by the judicious planting of our more common and hardy flowers, and pointed out how, with taste and forethought, a garden of this kind might be made an object of interest in some feature or other nearly the whole year through. Gardening, like many other things, he remarked, could never be learnt from books alone; and satisfactory results were only attainable by devotion and study of the different natures, positions, and requirements of the various kinds of plants which might be employed in gardens, and even those found on commons or in woods.

Such plants were, for the most part, inexpensive—a primary consideration to those who were unable to devote a large sum of money or much time to the management of their gardens, and where a love of our more common flowers was cherished, as much enjoyment might be derived from them as from the more costly exotics of our glasshouses.

In defence of the soil of Weybridge and neighbouring districts much might be said; and although it was regarded as being perhaps the poorest in England, there were, nevertheless, multitudes of beautiful plants which would thrive and adapt themselves to their surroundings. It must be admitted, that its light sandy, porous nature, and the influence of the gravelly subsoil, were the great difficulties we had to contend with; but by taking every advantage of any depression, and making others near the plants, and by carefully conducting all superfluous water, by means of channels or pipes, to those spots, even moisture-loving plants might be grown, whilst the more elevated parts and banks might be reserved for those which would bear drier situations.

Circumstances often produced what were termed "faddists;" but in defence of successful fads, he related his numerous attempts and failures experienced in the cultivation of vegetables and fruit, but which had to be given up in favour of shrubs, herbaceous plants, and bulbs.

With a touch of that love of nature with which the whole address was replete, he strongly advocated the culture of various kinds of fruits for the benefit of the birds, which, he added, should be cared for and cherished as much as the flowers of a garden.

Next came a list of plants, which he had found would adapt themselves readily, and thrive remarkably in this poor soil with but very little attention. Amongst a number of things which he had brought was a fine healthy frond of Chamærops excelsa, nearly 4 feet across, and grown out of doors for twelve years; branches of Camellias in flower; Skimmia japonica, with flowers and berries, the luxuriant growth of all denoting their perfect development, growth, and health. Most of the Japanese Maples thrive, and in proof of this he had brought several varieties, and also a branch of Sciadopitys verticillata (Japanese Umbrella Pine), and some rooted rhizomes of Bamboos, to illustrate the facility with which they might be propagated and grown in dry sandy soils. All the British Ferns would thrive on shady sides of banks, and most of the N. American species, especially Polystichum acrosticoides, Adiantum pedatum, Onoclea sensibilis, Struthiopteris germanica and virginica. Osmundas, and many others, were as much at home as in more favourable moist places prepared especially for them. For covering the lower parts of the trunks of the very tall Pine-trees there were numerous climbers, as Roses, Clematises, Ivies, Kerria japonica, and even Rhododendrons might be trained up them.

In conclusion, he would impress upon all who wished to improve their gardens that there was not a single spot which might not be made attractive and of interest, however bad might be the soil, or unfavourable the aspect, if the right choice of plants be made.

PLANT NOTES.

PRIMULA FLORIBUNDA AND P. VERTICILLATA.

THESE are two most useful Primulas for winter and spring flowering in the greenhouse. Although they are not so large and showy as varieties of P. sinensis, they deserve to be much more widely cultivated than at present. P. floribunda is a Himalayan species, and bears rather small yellow flowers, arranged in whorls, on scapes 6 or 8 inches high. Seeds should be sown early in March, in pans filled with light soil, and placed in a warm pit. As soon as the seedlings are sufficiently large to be handled, remove them into 3-inch pots, putting three plants in each.

A few weeks later the plants may be placed in a cool frame, to remain there during the summer months. Give to each plant plenty of room, keep them close to the glass, and ventilate as freely as circumstances permit. A light shading will be necessary during the hottest part of the day. The final potting into 5-inch pots should be done when the plants have made a moderate number of roots, and without disturbing the three plants, which should be potted-up together. When they have become well established, the plants will need frequent root waterings, and all flower-buds that show during the summer must be removed. At the end of October, place the plants in the greenhouse, and they will then soon commence to bloom, and remain bright for a long time.

P. verticillata, a native of Abyssinia, is an old plant, producing light yellow flowers, on scapes, in two or three bracteate whorls. The leaves are covered with a white, mealy powder, and enhance the beauty of the plant. P. verticillata may be grown in the same way as P. floribunda, so far as the summer treatment is concerned. It is, however, a more delicate plant, and it is important to obtain sturdy plants, that are likely to pass well through the winter. In October they should be brought into a warm, light, and airy pit, and placed on inverted flower-pots. Careful watering during winter is essential, or the leaves will be liable to damp off. Towards the end of January the flower-stems will be seen, and the plants should be then transferred to the warm greenhouse.

ILSINGTON HOUSE, DORCHESTER.

THE mention of the name of Col. W. E. Brymer may remind some of my readers of a Dendrobium and a Cattleya that have been named in honour of the proprietor of Ilsington House, for both plants are well known and valuable. The mansion is situated in a beautiful park, with great stretches of lawn and meadows, interspersed with large trees, among them being some Limes and Beeches that are specially noteworthy. Some very fine Yews also stand out as single specimens, or are associated in clumps; and beds or borders of choice Rhododendrons make a picture of singular charm and beauty. The flower-garden is of good size, and the beds will soon be filled with various and showy plants, full of bright foliage and flowers.

Adjoining the mansion is a large conservatory, the roof of which is covered with Tacsonia Van Volzemii, whose pendent growths, and flowers of intense purplish-crimson, are thickly studded over the whole of the space. Planted out are large specimens of Dicksonia antarctica, with fine heads of spreading fronds, and tall stems, 10 to 12 feet high; with these are a number of large and handsome Camellias. On the front stages, amongst other plants, are numerous Cannas of the best varieties, including Italia and Austria.

Passing the gardener's house, we enter the long range of fruit-houses, and are much interested in the splendid appearance of the Peach-trees. In the late Peach-house the trees, instead of being planted at the front and trained on a trellis of the usual style, are planted across the house, some ten or a dozen of them, and fastened to wires that are fixed across the house right up to the roof, omitting, of course, the space for the pathway. These trees and wires are about 4 feet apart, and can easily be reached for tying, disbudding, or gathering. The method has proved satisfactory to Mr. Powell, the able gardener here, who describes the results as being very good. I have not found this method answer well in the case of early Peaches.

Passing into the late vinery, it was pleasing to notice the health and vigour of the growths. The Muscat Vines in another house were planted seven years ago, and are now in capital condition, the canes very strong, and the leaves all that could be desired. Another large vinery was planted twenty years ago, and a plant of Buckland Sweetwater, with three strong canes, always bears a very heavy crop of fruit. In one Peach-house the front trellis is used for Plum-trees. This range, facing due south, must be about 200 feet long.

THE ORCHIDS.

One of the features of this garden consists in the exceptional specimens of Dendrobium Falconeri, and Thunias Marshalli, Bensoni, and Brymeriana. Of the former, a number of plants are growing on Fern stems inserted in pots, and made firm and secure by crocks, &c. The old growths are wired round the Fern stem, and new roots have entered freely, then from these old bulbs new shoots have pushed out in all directions, so that these plants, of which there were many, were really little cones or pyramids. The bulbs of the Thunias become as thick as one's thumb, and not more than 18 inches high. T. Brymeriana × was the result of a cross between T. Marshalli and T. Bensoniæ. The condition of the plants show plainly that the treatment they require is a medium heat and moisture, with plenty of light at all times, for in the early months of the year growth commences, bulbs are formed, and flowers expand in a period of four months or less. During the other eight months the bulbs are ripening and remain dormant until the spring. The practice is too common of keeping Thunias growing in the shade for too long a time, with a good share of heat, hoping to secure fine bulbs and blooms, but by such a method lengthened bulbs are produced that seldom flower. If in August there is no sign of flowers, it would be better to pinch off the top of the growths and stand the plants in a dry and cooler place. The bulbs would then thicken and harden, and plump eyes would be formed for the coming spring.

There are several houses devoted to the culture of Orchids, and many choice plants are to be found growing in them. In one house I noticed about a dozen and a half of good plants of Vanda teres, many of them 3 feet in height. These were at one end of the house, where but little shade is given. The plants were fastened to rods of Elderwood, with the bark still on them. To this soft bark the roots cling, and the plants grow with rapidity and vigour. In the same house are a number of plants of Cattleya gigas hanging from the roof. For many years these have made good growths, the bulbs being very plump. Calanthes in pits are making a good growth. In a house chiefly devoted to the Lælias and Cattleyas, were many more plants of C. gigas, C. crispa, good varieties of C. Gaskelliana, C. Bowringiana (very strong), and Epidendrum prismatocarpum. The rare Cattleya Brymeriana is much like a short-bulbed Lælia elegans; its flowers are of medium size, and the sepals and petals are of a pale rosy purple. The lip, which has a narrow, closely-folded tubular base, nearly 2 inches long, is yellowish below, and pale lilac, with the front part veined purple, the throat being a clear yellow, and the lower lobe rich magenta-purple. Mr. Powell takes the greatest interest in hybridising and raising of seedlings. The original plant of Dendrobium Brymerianum is now a plant of large size, and a specimen to be remembered.

There are numerous plant-houses in which flowering and foliage plants are raised and cultivated in quantity, and pits for the growth of Melons, Cucumbers, and Tomatos.

The kitchen garden is planted with fruit-trees in every convenient spot, and every outbuilding supports either Pear or Plum-trees. An avenue of Apple-trees is just now a very interesting sight, as the overhanging blossom is very abundant. *W. S.*

A RUN THROUGH A TULIP-FIELD.

THE Daffodils are gone by this first week in May, after we had seen them in flower at Ard Cairn since January. The cycle of seasons how they skip round! The May Tulips were a blaze of colour. What are called French Tulips, grown in Holland by the million, must not be confounded with the old-fashioned, grandmother border-flowers of 200 years ago. These late-flowering, beautiful varieties, that were all the rage before Calceolarias, Lobelias, Golden Feather, Black Beetroot, led to their consignment to the rubbish-heap some thirty years ago. Most of the lovely colours here mentioned were known to exist in my grandfather's nurseries near Mallow about 1830, and it is assumed the old pioneer nurseryman must have brought them from England, he having been a pupil in Kew Gardens, and one of the old school. This was at the end of the last century. There is no trace of this old-fashioned nursery now remaining, unless in the presence of some fine specimens of Copper Beech, Golden and Weeping Ash, and some Beech Hedges, &c. The house is still standing, but cattle graze on the site of a once old-fashioned lovely garden—one such as the pen of Lord Beaconsfield, in *Lothair*, fully described. Here were great tall Pæonies, all sorts of Gentians, Rockets, old-fashioned Dahlias, Pinks, Carnations, Potentillas, Columbines, Honeysuckles, Sweet Briars, "Dusty Millers" (Auriculas), all colours in double Primroses, including the scarce crimson Pompadour; Scotch, Cabbage, and York and Landucks were wont to make their nests, using the dried leaves for the purpose. Then bowers of Everlasting Peas and Jasmines, great tall Lupins, Hepaticas, including the rare double blue; and quails and corncrakes frequented this spot—the former I have not seen for forty years in Ireland. On a May morning in those times, before the mowing-machine was thought of, and when the scythe did the work, the perfume from the cut-grass, the odour from the Tulips, Wallflowers, Hawthorns, the song of the birds, even the noise of the whetstone on the scythe, which came in at the windows, made such a delicious whole that one could not remain in bed. Then one had a romp in the mounds of green grass, and the white smock got stained green, and had to be dusted over with flour for fear of mother's anger.

The late Anthony Trollope thought out some of his earliest novels sitting within a summer-house smoking in this old garden during the years '47, '48, and '49. He loved the old spot, and rented it for three years!

But now to talk about the blaze of colour in Tulips at Ard Cairn, and to look at them this lovely May morning, when they forcibly remind one of a field-day with Lancers, their pennons aloft in Phœnix Park. What can possibly afford such rich colouring as good blends of Gala Beauty, fulgens, fulgens lutea, elegans lutea, spatulata in scarlet, orange, and striped; Didieri, in three or four colours; then Bronze King and Queen, Sunray, Sunset, and Billietiana; Golden Eagle, Golden Crown, Buenovenuta, Neglecta Picta (various), Fairy Queen, rich heliotrope and yellow; John Ruskin, a lovely ripe apricot colour and yellow; the rare and scarce fawn-coloured variety Flava; Bridesmaid, Bouton d'Or, Ixioides, soft canary yellow, with black base or blotch; Gesneriana lutea, macrospila, Shandon Bells, Silver Queen, York and Lancaster. In white Tulips we have Snowdon, Didieri alba, elegans alba, &c. But to fill up the gap with extreme effect there must of necessity, for sake of rose and scarlet, be plenty of Tulipa Gesneriana var. major in its four colours. The latter so cheap and sweet scented. This Ard Cairn collection of May Tulips does not include the Darwin, old English or Flemish sorts, and as now seen is one of the richest in the United Kingdom. *Communicated, May* 6, 1899.

PÆONY DISEASE.

This disease, as occurring in England and Ireland, caused by a fungus called Sclerotinia Pæoniæ, is not perennial in the tissues of the host-plant. This season, I have had the opportunity of carefully examining many hundreds of diseased leaves, received from widely separated localities in England and Ireland. The disease, in every instance, is seen to commence at that portion of the leaf-stalk situated about half an inch to an inch below the surface of the soil, and if the leaf-stalk is examined when the disease is just commencing, there will be found in every instance one or two inches of perfectly healthy leaf-stalk below the diseased portion.

Within a short time after its appearance, the disease extends down to the base of the leaf-stalk, the edges of the leaves curl inwards, and soon the leaf bends over and dies. In some instances, where the disease is abundant, the Botrytis condition extends to the foliage also. All infection of the leaf-stalks is due to the presence of sclerotia in the soil, that were formed on the decaying leaf-stalks of the previous season. Of course, when the disease is present on even a single plant, the Botrytis spores are readily scattered by wind, and thus infect neighbouring plants.

Preventative measures.—On the first symptoms of the disease, indicated by the curling of the edges of the leaves, such leaves should be removed, taking care to pull away the base of the leaf-stalk. Spraying at intervals of four days with a solution of ammoniacal carbonate of copper would check the spread of the disease due to Botrytis spores. Where the disease has existed, the soil round the plant should be removed quite down to the crown, and fresh soil mixed with quick-lime added. *Geo. Massee.*

CYPRIPEDIUM "ALICE."

This is the result of a cross between C. Stonei and C. Spicerianum. The flower we illustrate (fig. 125) is a monstrosity, showing a common tendency in Orchids to assume a dimerous or two-parted condition. In the present flower, we have one sepal and one petal both placed in the same antero-posterior plane, and a central column which also gives indication of the presence of two stamens, not placed laterally as they are usually, but one opposite the other. The flower appeared in a plant exhibited by Messrs. Veitch & Sons.

COLONIAL NOTES.

SINGAPORE.

In answer to your inquiry, I would put myself to considerable inconvenience with pleasure, if I could find Pinus Merkusii anywhere here, or any other Pinus in our hills. I have never seen or heard of it anywhere in the peninsula, nor anything likely to be it, nor have I ever met anyone from Sumatra or Java who claimed to have seen it. I am prepared, however, to believe it exists. Our Coniferæ here are Dacrydium elatum, and a Dacrydium like a Spruce Fir, which never produces, apparently, fruit or flowers, and which has been, I believe, supposed at home to be only a state of D. elatum—it grows on Ophir and other hills; Podocarpus cupressinus, P. neglectus, P. species which I have not identified, and Dammara robusta. That is all I have seen or heard of. But you will remember our biggest mountains, Tahan, Kerban, and some others, have never yet been got at—at least, by anyone who would take the trouble to bring anything down from the top. There may be Pines on the top of them, but I doubt it very much. One may reckon Pines as northern (Himalayan flora) plants. Now, as high as I have been, I have never yet seen any Himalayan types here. Ranunculus, Primula, Gentiana, are all absent; they all occur, however, in Java, and often at no greater elevation than I have been in the peninsula. Linaria alpina was once found on Mount Ophir; I have hunted for it on two occasions, and could not find it, nor has anyone before or since done so; but that is the only boreal alpine I know of here. Indeed, our hill-top flora is more Australian than northern, so I do not expect to find Pines here at all. But you may depend that if I do, you will soon hear of it, and I shall attempt to get the thing alive to England. *Henry N. Ridley.* [P. Merkusii is recorded in books as occurring in some of the islands of the Indian Archipelago. Ed.]

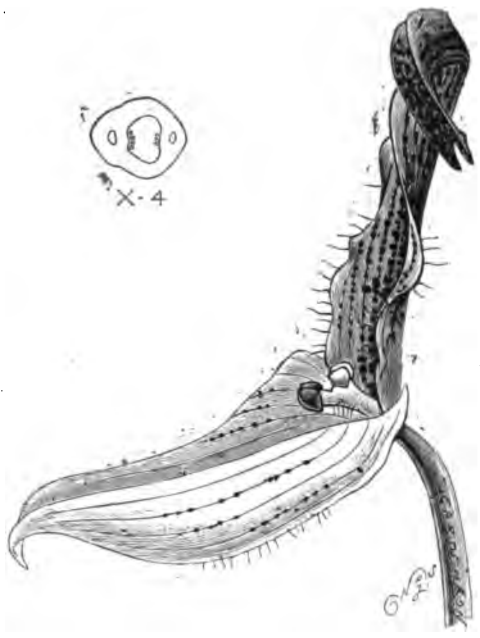

Fig. 125.—Cypripedium "Alice": malformed flower.

Sydney.

One of our pests here is the flying-fox—a gigantic bat with a spread of wings 2 feet across. These do immense damage to the summer fruits, if not scared away. This pest is disappearing with the settlement of the country, but the foxes are still sufficiently numerous to do much harm. They have only recently put in an appearance this year, but they were in time to work havoc amongst my late Peaches, of which they destroyed about ten cases. We erected bird-scares, which are effectual as long as the wind is blowing, but not at other times. We turned out with guns and shot a few of them, and scared off the rest, and after our first night's "battue" but few appeared. During the day they hang suspended from trees, generally choosing for their "haunt" the least accessible gullies. When a "haunt" is discovered there is great slaughter, all the people from the neighbourhood turning out to the work. In a sparsely-populated country like this, they often remain undiscovered for years. *A. P., April* 4.

BOOK NOTICE.

Flora of Kent, being an account of the flowering plants, Ferns, &c., with notes on the topography, geology, and meteorology, and a history of the botanical investigation of the county, by F. J. Hanbury and E. S. Marshall (Rev.), with two maps. (London: Frederick J. Hanbury, 37, Lombard Street.)

The title-page is really a table of contents, and so well does it indicate the nature of the book that not much remains for the reviewer to do, beyond advising all interested in the Flora of Kent to purchase it forthwith. Botanists have been impatiently waiting for this book for nearly a quarter of a century, but we do not think they will be disappointed now that it is placed within their reach.

The Kentish Flora is specially interesting from its great diversity—a diversity consequent upon the variety of physical conditions. In spite of modern "improvements," few counties possess so many delightful localities for botanical excursions. The chalk range from end to end of the county, the sea-side flora, the mud-flats of the estuaries, the thrilling excursions to be made along the downs near Dover, or in the undercliff between that town and Folkestone, the delights to be experienced in the sand-hills near Deal, and in the golf-links by Littlestone; the startling surprise felt by one who visits for the first time Dungeness in the early summer months, may all be specified in illustration of our assertion. Thirty-three out of forty-four British species of Orchids are to be found within limits of the county. Quite lately the Lizard Orchis, supposed to be extinct, has been re-discovered on the chalk formation. Small thanks to the inconsiderateness with which the fact was published. Happily, the habit which many of the tuberous-rooted Orchids have of passing a considerable proportion of their life underground may serve to preserve them from the ravages of plant-collectors. In any case, every field-botanist knows that Orchids are very abundant in some seasons in a particular locality, whilst in another season not a specimen can be found in the same field. The "Lizard" may thus escape entire annihilation. Cotyledon Umbilicus, Osmunda regalis, and Ceterach officinarum, are no longer to be found in their old localities.

On the other hand, some plants have been introduced, spread, and multiplied; such are Lepidium Draba, said to have been introduced with sacking, &c., on the return of the troops from the Walcheren Expedition. Dianthus Caryophyllus is reputed to have been introduced by the Normans. It is, or was, found on Rochester Castle walls, and similar situations, leading to the inference, first expressed we believe by Canon Ellacombe, that it may have been introduced by the Norman invader. Considering the large use of Caen stone, it is quite possible that some of the "introductions" may have been due to the extensive importations of the stone as building material. While speaking of introductions, we may note the record made in this volume of the occurrence of Senecio squalidus on the city wall at Canterbury. The present writer has to plead guilty to having introduced it more than forty years ago from the college walls at Oxford. The note from the late Mr. Gulliver, dated 1875, is therefore of much interest. Acorus calamus is recorded as an alien probably planted; but in our botanising days it grew in the Sturry marshes. Moreover, there is a tale current relating to this plant which, if it cannot be substantiated in every detail, is essentially correct, and which would go to show that the plant was native to the county. The tale is this: Many years ago—probably sixty or more years since—a native of Kent, somewhere near Maidstone, was advised by a London physician, whom he had consulted, to procure, for medicinal purposes, the root of the Sweet Flag. On enquiring where this was to be procured, the patient was referred for information on this point to the late Mr. Masters, of Canterbury, who had a good knowledge of local plants. On applying, accordingly, to Mr. Masters, the enquirer was informed in full detail where the plant was to be found, the locality thus minutely detailed proving to be a pond or piece of water immediate opposite the questioner's residence!

Many years ago there was an herbarium formed by Mrs. Grayling, in the Canterbury Museum. It was not likely to have been "critically" named, but at any rate it gave a very fair representation of the plants in the immediate vicinity of Canterbury. Perhaps—probably even—it is not in existence now, for when we saw it last, several years ago, it was evident that no care was taken of it. In the Dover Museum is a similar collection. Neither of these herbaria is mentioned in the list given in the volume before us, and there are probably also herbaria in the museums at Folkestone and Maidstone.

We have not space to advert at greater length to a most interesting volume—one of almost as much importance to the geologist as to the botanist, but we may, in conclusion, repeat what we said in the beginning, and advise everyone interested in Kentish botany to purchase this volume, for the very good reason that it is indispensable.

CONTINENTAL NOVELTIES.

GIANT WINTER STOCK.

"ONE of the novelties for next season," writes Mr. Ernst Benary, "will be a Stock of remarkable beauty, and bearing immense flower-spikes of large rose-shaped blooms of a bright rose-colour." The flower-spikes, which accompanied this note, were all that Mr. Benary describes the variety to be, and they also showed a branching, compact habit. It will prove a fine winter-flowering variety for pot-culture.

THE BERMUDA LILY.

IN continuing the study of the disease affecting the Bermuda Lily, the writer was authorised to visit Bermuda during the first weeks of April when the Lilies were mostly in bloom.

During a two weeks' stay, nearly every Lily field of importance was visited and examined. Great diversity exists in regard to the condition under which bulbs as well as other crops are grown. The soil of the Islands, as is well known, varies from a light "coral sand" with almost no organic matter or mineral constituents, such as phosphoric acid, potash, iron and free lime, to the deep or dark red soils which are almost clay in their nature, containing the finer silt-like sand with much organic matter, more or less iron and phosphoric acid, but often lacking in free lime. That the condition of the soil has a very great effect upon the vigour and healthfulness of the Lily is at once apparent to even a casual observer. In fact, the Lily is not different in this respect from most other crops. Bermuda soil scarcely ever gets a rest. While one crop is being taken out, another is put in, and sometimes it is the same crop year after year. The question of what fertilisers to use and the manner of using them becomes a very important one, and is beginning to be fully realised by the most progressive planters.

The Legislature has established a Public Garden to be conducted along the same lines as the experimental farms in the United States and Canada. The Superintendent of the Garden, Mr. G. A. Bishop, formerly of Kew Gardens, England, doing much to develop interest in agricultural subjects. Shortly after reaching the Islands, a year ago, he made a careful investigation of bulb culture from all its standpoints, and published a report. He recommended discarding and destroying all diseased stock and propagating only from vigorous, healthy bulbs, also to avoid land in which bulbs had been grown without rotation for several years. Mr. Bishop also experimented with different methods of treating the bulb to prevent developments of mites and fungi. As a result of putting these recommendations into operation, many growers have crops which are far superior to what they had last year. There are many instances, however, where growers preferred to follow their old custom, with the result that hardly a healthy plant can be found in their fields.

There are three diseases prevalent in the Islands, one known as "Yellows" is evidently brought on by a variety of causes. The first should be mentioned is a lack of lime in many of the soils, that is, lime that the plant can take up. A plant which is not rich in feeding roots is unable to take lime from limestone, and as this is the condition of some of the soil, the leaves of the Lilies growing in it are almost white. In other cases, yellowing appears to be due to a lack of iron; and a third cause for yellowing is decay and destruction of the roots by fungi and mites. The latter cause produces scattered cases, plants here and there throughout a field are white, while their neighbours may be perfectly green and vigorous. An examination of these yellow scattered cases always revealed an entire absence of feeding roots, or the destruction of the root-hairs of the feeding roots to such an extent that the plants could not obtain lime. It is, of course, evident that the bulbs of these yellowed plants cannot be as vigorous as those produced by plants having green leaves. As a matter of fact, these yellowed leaves cannot make any nourishment whatever for the dependent bulb, and unless they turn green again, as they occasionally do, after the production of new roots, the top is worthless.

Another disease which is very prevalent, and often very destructive to the leaves and stems of plants, is one known as "Ward's Disease." This is characterised by the appearance on the leaves of small brown spots, which in moist weather increase rapidly in size, finally destroying the whole top. Where fields are not properly sprayed with Bordeaux Mixture, this trouble may sometimes defoliate the plants shortly after the flowering period, cutting off much valuable and important nourishment from the bulbs. That this disease has had something to do with the general weakening of the stock cannot be doubted.

The third disease is one which we recognise here: the leaves are deformed, light-coloured, often covered with numerous, minute, shrunken dead spots, due to the attack of green-fly, and spots produced as the result of the general weakened condition of the bulbs. Such plants seldom, if ever, produce a good flower, and their roots are always badly infested with mites and fungi. This trouble is readily distinguished from the former, and undoubtedly is a direct result of a weak bulb. These are the plants which the Bermuda grower must carefully weed out and destroy. If this is done systematically, and careful attention is given to renovating and improving the soil, it will not be long before the forcer of Bermuda bulbs can count with some certainty upon his crop of flowers.

I was much pleased to find a very strong sentiment against cutting and shipping of flowers to sell in the United States. The best growers unanimously condemn this proceeding, but it is difficult to prevent unscrupulous people from giving the Islands a bad name in this respect. The injurious effect upon the bulb of cutting off several inches of the stem with the flowers and buds, has been many times pointed out. It is as injurious as if the top had been killed by fungi, and often more so, as it is a great shock to the plant, and has a tendency to cause premature starting of the bulbs.

The practice of disbudding, leaving only one bud to a plant, is quite generally followed, and there can be little doubt but that it is beneficial to the plant and hence to the bulb; but this is an entirely different process from cutting off the top, as everyone acquainted with the principles of plant growth knows.

Those of us interested in bulb culture have sometimes thought that this was the main industry of Bermuda; but as a matter of fact, while it is one of the very important industries, it is said to be far exceeded by the raising of Potatos and Onions. These are also mainly shipped to the New York markets for distribution over the United States. The Onion appears to be subject to a number of important diseases. The greatest loss has been suffered this year as a result of the attack of thrips. The work of these little insects causes the tops to become blotched with white dead spots, and if the thrips are very numerous the tops are killed, all except the young growth. The spots produced by thrips are often followed in damp weather by decay-producing fungi. One of these is Macrosporium. This fungus is thought also to attack healthy plants, and is very prevalent in some parts of the United States. A fungus disease which is more common is known as the Onion-rot, and is related to the fungus which causes a similar rot of Potatos. The roots of the Onion and the bulb are often attacked by the same mite that attacks the Lily bulb. We observed a number of instances where considerable damage had been done in this way. The trouble on Onions, however, will likely not develop to any great extent, owing to the fact that they are grown from seed obtained from Teneriffe. Onions should not be used for rotation with Lilies. *Albert F. Woods, Division of Vegetable Physiology and Pathology, U. S. Department of Agriculture, in "Florist's Exchange."*

THE HERBACEOUS BORDER.

TRILLIUM GRANDIFLORUM.

THIS charming Trillium is so much admired that any improvement in its flowers can hardly fail to be appreciated. The reference to a large flower shown among Messrs. Barr & Son's plants at the meeting of the Royal Horticultural Society, on Tuesday, May 16, leads me to remark that there appears to be considerable variation in the size of the flowers. Three or four years ago a friend in Canada sent me a number of clumps collected in Ontario. Several of these were put together in a large pot, in which they have since remained. One of these plants has annually produced flowers considerably larger, and consequently finer, than those of the others. The difference mainly consists in the breadth of the petals. In the same pot one can discern a considerable difference in the size of the blooms, there being nearly an inch of variation in the width of the petals. These plants have not been disturbed since their first planting on coming from Canada, so that the difference in size can hardly be accounted for by attributing it to cultivation. One plant also comes with a green mark—an elongated, pointed blotch—in the centre of each petal. The soil and cultivation do, however, account very largely for the comparative beauty of T. grandiflorum in gardens. Thus, in my own garden, a portion from one of the best plants I have ever met with never equals in point of size nor beauty its parent. In the interesting and well-kept garden whence it came, the Trillium is always grown in a border under the shade of Apple-trees. The soil is not what one would think a good one, being light, dry, and poor from the large proportion of granite-sand in it. Yet the plants are very fine, and soon increase to large dimensions. The last time I saw the Trilliums in flower in that garden, one clump had thirty expanded flowers on it, although it had been divided about two years before. The flowers are much finer than any I can secure in my soil, which is light and dry as well, but which I have tried to make amends for by planting the Trillium in a low, half-shaded position where it can be well supplied with moisture. It is to be hoped that others who have plants which show flowers of exceptional size will try to increase them when possible.

IBERIS LITTLE GEM.

In the same report mention is also made of Iberis Little Gem, which quite deserves the prominence given it. It has been in my garden since early in 1897, and is now in bloom for the third season since it came to me from Winchmore Hill. It has increased in size, as may be supposed, since that time, but this has been more in diameter than in height. Measured to-day in full bloom, it is exactly 5 inches in height in the centre—and highest part—of the plant. It is grown on a sunny rockery facing almost due south, and in light and sandy peat. It is one of the most valued rock-plants I have because of its hardiness, free-flowering habit, and—a notable merit—its giving no trouble. It blooms as freely as the taller varieties of I. sempervirens, to which I suppose it belongs. It roots easily from cuttings, and one would hope, will soon be quite plentiful. There are many positions in which this pretty little plant can be grown, where the larger Candytufts would be out of place.

IBERIS PERFECTION.

One is naturally led to refer to this Candytuft after speaking of Little Gem. Its value does not, however, consist in a dwarf, neat habit like the foregoing, but in the large size of its corymbs and individual flowers, and in the purity of its white blooms. One would like to know to whom we are indebted for these improved perennial Candytufts. He is a bold man who applies the name "Perfection" to a flower if he intends it to remain appropriate, and in view of the advance still likely to be made with hardy flowers, one can only say that the name is appropriate enough in the meantime. Climax is another good Candytuft, and both are, I consider, superior to the one named I. sempervirens superba. *S. Arnott, Carsethorn, by Dumfries, N.B.*

FORESTRY.

THE LEAFING OF TREES.

SPRING is a season so popular among lovers of Nature, that anything relating to it awakens pleasing associations and ideas. In the poetical mind spring is invariably regarded as the symbol of regeneration of youth, and the awakening of dormant energies into growth and action. It is evident that most of these ideas and associations owe their origin to the vegetable world, for it affords by far the most striking illustration of those periodic alternations of active and passive existence which are more or less peculiar to organic life.

Probably in no class of plants is the phenomenon more striking and attractive than in the bursting into leaf of deciduous trees and shrubs, for the change from bare twigs and apparent lifelessness to the tender green of the young foliage is both sudden and beautiful in its effect, and possesses for the first few days the additional attraction of novelty. The most pleasing feature which presents itself in this leafing process is the great variation in point of time, not only between the leafing of different species, but also between different individuals of the same species. It is a well-known fact that some species require much more warmth to start them into growth than others, the former being classed as late, and the latter as early varieties. Various attempts have been made to determine the exact amount of heat requisite to start into growth different species of the vegetable kingdom, and "thermal constants" have been formulated which are supposed to represent the warmth of the sun, reckoning from an imaginary year upwards, necessary for the development of different phases of growth. With some plants reported observations at the same and different stations have resulted in approximately identical totals, although the methods of reckoning, and the numerous factors of growth other than heat, render the science of "phenology" of a more or less theoretical nature.

From annual experience, however, we know the warmer or colder the local climate, the earlier or later vegetation shoots into growth or becomes developed, while soil, situation, and exposure also exert considerable influence on the process in question. All these influences upon growth are so well recognised, as to be accepted as a matter of course by gardeners, foresters, and farmers, and the result of them is invariably anticipated in cultural and other operations peculiar to the calling of each. But in the leafing of trees a factor is brought to view which is probably less clearly seen in other forms of plant life, viz., individuality.

In many cases, the growth and development of certain species are too often regarded as of a fixed and definite nature, and the characteristics of one plant taken for granted as being typical of the species. Close observation, however, demonstrates the fact that no two individuals are exactly alike, either in form, colour, or mode of growth, and with some genera this variation is greater between individuals of the same species than between individuals of two different species. In the case of trees, habit of growth, and the comparative earliness or lateness of beginning and finishing it, are the most striking characteristics of individuality; and to the latter, spring and autumn foliage owes a great deal of its beauty. In a mixture of early and late leafing species, the greatest variation in point of time will be seen, of course, but trees of the same species, and growing side by side, will be found to vary to a much greater extent than might be supposed. With some early species, such as the Larch, a spell of cold weather will greatly increase the difference in the time of leafing of two individuals, but, as a general rule, a difference of three weeks or a month can be observed in the leafing of trees growing side by side, and with the same exposure and soil. With the Beech, considerable intervals elapse between the earliest and latest, varying from a fortnight in some situations to a month or even longer in others. The Spruce is also a tree which shows a marked individuality in this respect, probably more so than any other, for as much as six weeks will sometimes separate early and late individuals. The Oak rarely shows a difference of more than three weeks, although it is a more difficult matter to note the first appearance of the leaf with this tree than in the case of the Beech or Larch. The differences noted above vary of course with the season, a quick, warm spring shortening, and a long, cold one lengthening the intervals by a week or ten days. Another peculiarity I have noticed with the leafing of indigenous trees, is the fact that trees growing on north slopes are frequently earlier in leaf than those growing with a greater exposure to the sun. Why this should be so is not easy to say, unless owing to the fact that plump, well-ripened buds are longer in bursting than those on badly-ripened shoots. Differences due to elevation and latitude are, of course, more strongly marked still; and a vast amount of information on this subject has been gathered together by the German Forestry Research Stations, the chief features of which were published two years ago. *A. C. Forbes.*

(*To be continued.*)

HOME CORRESPONDENCE.

THE GARDENS AT POWIS CASTLE.—On the occasion of a recent visit to Powis Castle, Welshpool, I was pleased to see that this grand old place fully sustains its past reputation amongst the famous gardens of this country. Improvements effected by Mr. Lambert may be seen everywhere. Owing to a large and increasing demand for ornamental plants for house-decoration, Pines are not now so extensively cultivated as formerly, the pits only being utilised for the purpose. The span Pine-stoves have been remodelled, and adapted to the cultural requirements of decorative and flowering plants. Noticeable amongst the indoor plants are fine batches of healthy Malmaison Carnations, well-coloured Codiæums, Cordylines, and Caladiums. Calanthes, which are always fine at Powis, have started away again strongly and well. A batch of Acalypha hispida (Sanderi) was particularly noticeable; Eucharis are also cultivated very successfully. Early Melons in several structures are swelling-off a crop of handsome fruits. Strawberries on shelves were abundant. The greater part of the vineries have in recent years been replanted, and now look most promising. Some well-trained young Apple-trees in the kitchen-garden promise well. Peaches and Apricots on walls, despite an unfavourable season, have set an abundant crop. Chrysanthemums are represented by several hundred sturdy plants. Extensive alterations and additions are being made to the pleasure-grounds, which, when completed, will greatly improve the place; and last, but certainly not least, a handsome, commodious, and convenient bothy for the young gardeners is in course of erection. *W. H. W.*

COTTON PLANTS IN THE BOTANIC GARDENS, LIVERPOOL.—Amongst a number of these interesting plants (Gossypium barbadense) cultivated here last year, one was noticed that produced a greater number of pods than others, and was dwarfer in habit. Towards the end of the season cuttings were taken from it, and at the present time they are bearing a number of pods, already the size of Walnuts. The plants are also considerably dwarfer than those raised from seeds taken from the same plant. *J. G.*

RHUBARB LEAVES AS A VEGETABLE. — More than twenty years ago I was staying at the house of a French friend at a town in Burgundy. One day a dish appeared at table, which my host informed me was Rhubarb, of which he had heard the English were very fond. It consisted of the leaves, stalks and all, cooked as a *purée*, after the fashion of Spinach and Sorrel. To me it was not agreeable, and I infinitely preferred Sorrel—its near relative. But then, it may have been my bad taste and want of education. At the same table, young Globe Artichokes, split longitudinally, appeared raw, as a salad, and were eaten by the family at every meal. Here again it was probably my bad taste; a single trial revealed a flavour such as I imagine young Fir-cones possess, and I could not again be persuaded to deprive the family of some portion of a delicacy. *R. McLachlan.*

VINE-MILDEW.—Is Mr. Mallett's method of treating the Vine-mildew, by thoroughly syringing Vines with water at boiling point, old, or quite new? Certainly I have never heard of any such treatment previously, but others may have done so. If any readers have seen hot water so tried, or have themselves used it, will they detail the effects. I regard what Mr. Mallett has told us as the most important pronouncement in relation to any kind of plant disease made since the introduction of the famous Bordeaux Mixture. It has the merit of being a cheap remedy, and if it be so effective on Vines, and so harmless, then why not on numerous other plants as well. Plantsmen as well as growers of Grapes, will be interested to learn that hot water destroys that inveterate insect pest mealy-bug, and if it will kill that, then there is no insect pest that its application will not destroy; just as if it kills Vine mildew, it will kill other plant funguses. Tomatos are very subject to fungoid disorders, will these plants bear such drastic treatment? may Peas infested with mildew be similarly treated? Will hot water cleanse fruit-bushes of the mite, aphis, or red-spider? What if hot water be a remedy for the Black-Currant mite, what a gain would that be. Evidently we shall have the getting of myriads of things into hot water literally, or hot water on to them. Perhaps it will kill woolly aphis on trees. Perhaps dipping Auriculas affected with that pest into hot water will destroy it. The imagination seizes greedily upon myriads of possibilities for the beneficial use of boiling water. Oh, for the desired school of experimental horticulture, where its effects may be fully tested. *A.*

THE LATE JAMES KELWAY.—To be portrayed, described, and praised after death in the pages of the *Gardeners' Chronicle* makes your journal into a species of horticultural Wallhalla, for to be thus honoured is honour indeed. James Kelway, besides living a very long life, lived a most useful one, and in relation to horticulture, a great one. How readily is his life's work praised, now that he is gone. Strange was it, to me at least, that when what were called "honours" were, a couple of years since, being so lavishly given away, the "grand old gardener" of Somerset should have been ignored. Some far less worthy than he might have waited until they had become worthy. But, honoured or unhonoured, James Kelway has left behind a name and reputation that will live when that of some others have been forgotten. *A. D.*

RETARDING PEACH AND NECTARINE-TREES.—The destruction of the flowers of Peach and Nectarine-trees on open walls in some parts of the country by the early spring frosts, should point out to gardeners the necessity of inventing some more successful method of protection than that which now obtains, or of retarding the flowering season of these trees. Something more is required than double fish-netting, tiffany, and the like, to exclude such frosts as we have recently experienced, and in cases of heavy storms with sleet and snow, much damage may be done to the flowers by allowing the protecting material to flap against them [It is usual to guard against this. Ed.], to say nothing of the exclusion of bees and other agents for pollenisation [The trees should be exposed during the day. Ed.]. I am fully convinced that protecting material does more harm than good. When in charge of some gardens on the south coast, I was desired, much against my will, to cover a wall of trees, and accordingly did so, four trees remaining uncovered on account of insufficiency of material. These four were the only ones which produced anything like a crop, they were also quite free from blister, whilst the other trees became badly affected. At Isleworth no protection of any kind is used, yet a fairly heavy crop is always secured, that of last year being somewhat below the average. This year only four trees out of sixty have no fruits, two of those being very young and two very old; the others are showing abnormally heavy crops, and as many as forty fruits have been counted to the square foot (sample shoot enclosed). Until this date (May 26) I have removed nearly a peck of young fruits, and many more have yet to be thinned out. The reason for this success is not far to seek. It is a practice amongst gardeners to plant Peach and Nectarine trees on raised inclined borders; the object being to secure the maximum amount of warmth from the sun's rays, thus rendering the produce of that border a week earlier than that of the level ground. Is it not this additional warmth that hastens root-action, and as a consequence, early flowering? Trees on a level border in these gardens prove that it is so, when compared with those in an inclined border on a neighbour's wall, which runs parallel with my own, 50 yards distant. The climatic conditions, the aspect, and the varieties of fruit are identical, yet I have a heavy crop and the neighbour has not any, because his trees flowered a week earlier than my own. I may add here that when the flowers were dry at mid-day, I pollenised them by forcing air among the organs by means of a garden syringe fitted with a single jet; it is much quicker than the "rabbit's tail" and other methods, and is most effective in dispersing the pollen. The annual forking of the surface of the borders also conduces to early flowering, as the warmth of the sun's rays is admitted thereby to the roots; unless the soil is unusually retentive, or has been fouled by frequent mulchings, such annual forking is really unnecessary. I think every nurseryman who raises fruit-trees will agree with me that the best rooted trees in nursery beds are those close to the walks, and that the best roots of such trees are found under the walks where the soil is trodden hard. Mulching is perhaps necessary during summer to conserve moisture in the soil, but manurial aid could be applied in the form of artificial manures at a cheap rate, without fouling the soil. If annual forkings effect anything, they encourage the feeding roots too near the surface to be safe from drought; and on inclined borders forking has to be done several times during the summer, in order that water may be admitted to the roots, this water being applied at considerable cost of labour, and then insufficiently done. Trees on level borders may be soaked conveniently. It is not possible for water to stagnate on level borders if the drainage below the trees be in good order. Where wide inclined borders exist, and are cropped with early vegetable produce, as is the case in these gardens, a plateau could be levelled thus , 6 or 8 feet from the wall, thus securing a warm inclined border for such crops, and a cooler level border for the trees. Lastly, the foot or more of wall-space covered by the inclined border becomes part of the paying area above the trees on the level. *Geo. B. Mallett.*

FROST AND THE FRUIT CROPS.—A succession of frosts from the 24th to the 28th of May have caused much injury to vegetation in this district, and in the Valley of the Ouse. The lowest recorded temperature on the ground is 25° Fahr., and following a considerable rainfall, this has wrought devastation amongst Potatos and other vegetable crops, while the earliest Strawberry and Apple-flowers have been cut in many places. It is strange that we have had three similar periods of several days' frosts in March, April, and May; but the last observation, though dealing with much higher temperatures than in the two preceding months, yet show far greater and more general damage. *R. L. Castle, Ridgmont, Beds.*

LATHRÆA SQUAMARIA.—On p. 329 of the *Gardeners' Chronicle*, under the heading, "Cambridge Botanic Garden," I observed the mention of this remarkable parasite. L. squamaria is growing in the pleasure-grounds at Wentworth on the roots of Ilex aquifolium. [L. squamaria is common in England, but not the prettier L. clandestina, except where naturalised. Ed.] It has the appearance of certain species of Orobanche, to which family it belongs. *P. Bolt, Wentworth Castle.*

WOMEN AS GARDENERS.—Superior man cocks up his nose mighty high when he hears or reads of women as gardeners. There is one thing very certain in relation to women in connection with the vocation of gardening. It is that they bring to its study far more earnestness, steadiness, attention, and study, than the superior males do. If men-students were but endowed with woman's living earnestness it would be much better for them. I saw pretty well last summer, when giving lectures weekly to some twenty-five young women and from fifteen to sixteen young men, at the same hall, that whilst the males took no notes and gave little attention, the females gave the closest attention and took notes freely, also at the close asking questions. This was the experience of other lecturers. If some ten years hence men find women largely displacing them in the vocations of the world, let them blame themselves and not the perseverance of the ladies. *A. D.*

THE LATE MALCOLM DUNN: PROPOSAL TO RAISE A MEMORIAL.—Horticulture is, indeed, the poorer for Malcolm Dunn's death, and it will be very difficult to fill the gap so caused. The last issue of the *Gardeners' Chronicle* contained an interesting tribute to his many good qualities, all of which was true both in chapter and verse. There are hundreds who would testify to his extreme readiness to advise and help others, and the writer of this note in particular is not likely to forget the kind and fatherly counsel given him some twenty-seven years ago. I venture to say the name of Dunn is still green in Co. Wicklow, as it is in Scotland and England. A memorial of some kind in honour of this worthy man is sure to be raised, and whatever shape it takes, whether in the North or the South, I shall consider it an honour to subscribe my mite. Though gardeners, as a rule, are not blessed with too much of this world's goods, I am sure there are large numbers of the fraternity who would only be too pleased to contribute to such an object. *J. S.*

PARADISE STOCK.—I enclose a cutting from the *Field*, and am astonished that such heresy should be published by any paper. Although I am in touch with most of the Kent growers, I never heard of such a failure; and such a retrograde step as a wholesale condemnation of the Paradise stock points to the probability of the grower having either purchased cheap stuff from the Continent, or trees on the French Paradise, which is well known to be worthless, and which none of our best nurseries use. Quite recently, in my paper before the Society of Arts, I drew attention to this fact. When one sees the enormous gain to growers the use of the best Paradise stock has been, in point of fertility, early bearing, and heading, when trees on Crab stocks fail, I feel that such a libel should not go unanswered; and in connection with this subject, I may mention that I have grand healthy Apple-trees on Paradise thirty years old. It would be interesting to know from others the age of trees on this stock which are doing well or otherwise. *Geo. Bunyard.* [The paragraph in question says, that out of several thousands of Apples on the Paradise stock, not twelve are now alive after an interval of "some years ago." The writer recommends the Crab as a stock; but if he is correct, why graft at all? Ed.]

THE DOUBLE DARK WALLFLOWER.—Mr. W. Barr is to be congratulated on a notable find. He has secured stocks of the true old Black Wallflower, as it was called fifty years ago, when it was not uncommon in gardens. I saw it growing and flowering but a few days since, and gladly recognised it as the real Simon Pure, the lost sheep of the Wallflower family now found. It has similar habit to that of its better known compeer, the double yellow Wallflower, is fairly robust, and sends up from strong shoots good long spikes of bloom. We have seen it of late at the Drill Hall, that bourne to which all good things, old and new, inevitably come from somewhere, which shows that it is pretty plentiful, if not very common. Doubtless, even this fine double form suffers because it cannot be perpetuated from seed, but then so little time and trouble are needed to cause plants to be produced through cuttings put in under a hand-light or in pots stood in a frame. The flowers, whilst commonly called black, are really of a heavy maroon colour, differing materially from those of the russety-red variety, by so many regarded as the true form. It used to be known as Cheiranthus cheiri hæmanthus, or the "double-bloody flowered," which was a rather sanguineous appellation. We may still, with fair consistency, term it the Double Black Wallflower. *Kingston.*

KERRIA JAPONICA.—A large-flowered form of this Chinese shrub is now in fine character on one of the walls at the Chiswick Gardens of the Royal Horticultural Society. The blossoms are larger and fuller, as well as deeper in colour, than the common double form; as the last is growing near it, a comparison is afforded. It is thought to have been sent to the gardens by the late Col. Trevor Clarke, but nothing is known as to its origin; but it makes an imposing wall-plant. With whom and when the double form originated does not appear to be known; but Mr. G. Nicholson, in his *Dictionary of Gardening*, states that the single-flowered form is a much more elegant plant, having a very graceful habit, and being nearly always in flower. *Visitor.*

ACROPHYLLUM VENOSUM.—It is said that this once popular New Holland plant has become very scarce. One reason for this is to be found in the fact that it is difficult to cultivate with anything like success. It is not that the plant dies outright, but it falls away into a stunted habit of growth, out of which it is sometimes difficult to lead it. Time was when finely-grown and bloomed examples of this plant were seen at our large flower-shows in collections of stove and greenhouse plants; and though a single spike of bloom is not much of itself, a number of them on a well-grown specimen presented an attractive sight. "To grow it successfully," wrote Mr. Thomas Baines, "it requires the best soil that can be got, soft-water, and close attention. On no account should it be allowed to stand out-of-doors, not even in the finest summer weather. In one respect it differs from most other greenhouse hard-wooded plants—it will not long bear being under the full influence of the sun in a light house during the summer." Mr. Baines' favourite compost was the best fibrous-peat, carefully broken by the hand, all small particles being rejected, adding one-seventh of sand, and potting very firmly. *Ealing.*

OLD VARIETIES OF TULIPS AND DEPARTED TULIP-GROWERS.—The florists' Tulip, of all flowers, perhaps, needs open quarters and a pure atmosphere in which to develop in perfection its richly marked blossoms. It is this necessity, more than lack of interest, in the flower which in the course of the past thirty years has operated to banish it from suburban gardens. Sixty years ago, collections of Tulips were grown in the City Road, London, and one cultivator, a Mr. Franklin, raised a great number of seedlings, and obtained some fine forms and colours; a Mr. Bowler, of the Albany Road, Camberwell, flourished at the same time, and among the varieties which rectified with him, a bizarre, Everard, caused a great sensation in London Tulip circles. Mr. Greig, of Hackney Wick, obtained a number of seedlings raised by a Mr. Drinkwater of an earlier date, and also by a Mr. Clark. A "rose" named Juliet appeared in Mr. Greig's bed, for which, it is stated, he refused a very large sum of money. It is reported that Mr. Clark had a seedling bed of eighty rows, representing some 600 bulbs, and there is reason to believe that cross fertilisation was not much resorted to in those days, seed-saving being a somewhat haphazard process, and therefore the appearance of gems in a seed-bed was by no means frequent. John Goldham, presumably the father of Henry Goldham, of Tulip fame, purchased a number of Mr. Drinkwater's and Mr. Clark's seedlings in the breeder stage. He had himself been a raiser of seedlings at Camberwell for some years. Goldham spared no pains to acquire a collection of fine forms, and his sound and well-directed judgment helped him greatly in making his selections. He seems to have stood unrivalled and alone in regard to the value of his collection. It is reported that Mr. Goldham had a fine strain of a bizarre named Louis XVI.—a variety raised in Holland—and he was known to have refused the sum of £73 10*s.* for it. Mr. Brooks, then occupying a nursery at Ball's Pond, Islington, also had a collection, and sold some highly-esteemed varieties at high prices. Mr. Davy was then living in the King's Road, Chelsea, where he grew Tulips, and raised a variety, but of which class I do not know, and named it "La joie de Davy"; for this flower he was offered the sum of £157 10*s.*, and declined it. The father of the brothers Lawrence, of Hampton, obtained a bizarre named Polyphemus, obtained from a breeder by Mr. Clark; and the sum of £50 was given for four bulbs of it, though it was known that other persons had it also. A feathered byblœmen named Fanny Kemble, also raised from one of Mr. Clark's breeders, and of which there was but one bulb and three small offsets, was sold to Mr. Davy for £100. This flower was figured in some of the florist's publications of the day, and was ranked very highly by Tulip exhibitors for many years afterwards. Mr. Davy died soon after this purchase, and Mr. Goldham became the possessor of the variety, paying nearly the same price for it. Mr. Holmes, of Clapton, was also a noted grower, and broke a valuable bizarre named Louis XVIII. At his death his collection passed into the hands of Messrs. Milliken & Groom, of Walworth; and this variety was afterwards sold to Mr. Goldham for £42. At that time George Glenny was coming to the fore as an authority on Tulips, and it is said that he bought the stock of Mr. Bowler's Everard, comprising seven bulbs, for which he paid the sum of £140. There is reason to believe that in the forties—and relatively to the population of London in those days—there were as many growers of Tulips in the suburbs as there are of Chrysanthemums in the present day. Up to the middle of the sixties it was not an uncommon sight to see small beds of Tulips in the back gardens of the houses abutting on the Walworth and Camberwell Roads, with their protecting canvas-covering in May. To the worthies whose names have been referred to, there succeeded John Edwards, the Dicksons, the brothers Brown, Scarnell, Strong, Sanders, Hunt, Betteridge, Turner, Colman, &c. One by one these gave up their collections, or died, and no one succeeded to them. It will be matter for regret if a flower with such a singular and fascinating history as the Tulip should cease to be cultivated in the southern counties of the kingdom. *R. D.*

GOOSEBERRY CLUSTER-CUPS.—This fungus disease of the Gooseberry, resembling to a certain extent the Orange-rust of the Rose, is spreading rapidly, so much so that I fear a magnificent crop will be lost if it be not checked in its progress. [Our correspondent sent for our inspection some capital examples on leaf and berry of this troublesome parasitic fungus. Ed.] At first the fruit and leaves only were affected, but afterwards it spread to the young shoots. I have several hundred bushes distributed over a large garden, and not one is free from the fungus; and in a neighbouring garden the disease is very prevalent. We experienced sharp frosts during the third week in March, just as the bushes were coming into full growth, when no apparent injury was done, although 14° and 17° were noted, and during the month succeeding the berries swelled satisfactorily. From May 2 to the 10th, the weather was extremely cold, but fine, with a parching east wind. On May 11 the weather changed to rain, with some thunder, and it is since that date that the fungus has spread over the bushes. *S. Platt, Loughcrew Gardens, Oldcastle, Co. Meath.*

THE ROSARY.

PREPARATIONS FOR THE COMING SEASON.

Whatever may be the character of the approaching season, there is some essential work that all who wish to compete at the forthcoming exhibitions will have to consider; and as I write for those who are novices in that interesting branch of Rose growing I will notice some points which must be carefully looked to. In the first place, the beds must be well looked over, and if there are any shoots which belong to the stock and not to the Rose, they must be carefully cut away. Where Roses are grown on the Manetti, these shoots are more likely to be present than when the Roses are worked on the seedling Briar or Briar cutting; in the former case they come from the stock itself, and in the latter from suckers thrown out from it. The former are the more insidious because the foliage of the Manetti is so like that of some of our Roses, and a young grower may unwittingly be nourishing an enemy which he fondly believes to be a friend.

As the shoots advance great care will have to be taken to get rid of the maggot, which often destroys the hopes of the young grower; the habit of this pest is to get into a couple of leaves and then affix them to the bud, at which it begins to work away, and when once it has the opportunity of doing this it is too late to apply any remedy. I have never found that syringing is of any use; the only remedy is to go through the Roses every morning, and wherever the commencement of this destructive work is noticed, to at once destroy the maggot with finger and thumb. It is not pleasant work, but no one who loves Roses and wants to make a good appearance, will quarrel much with this unpleasantness. Should aphis appear (but of which as yet I see no trace), syringing with some of the various advertised insecticides must be carried on; and here I would give a word of caution—in using these various preparations be sure to adhere to the directions given with them. Some persons are apt to think that if 1 oz. is recommended it would be a very good thing to make it a little stronger, and take 2 oz. instead of one; this will probably disfigure, and it may injure the Rose as well as the aphis. Another point which the novice in Rose growing often finds it very hard to carry out is that of disbudding. There are some Roses which have only one flower bud on a stem, while there are others which have a cluster of three, four, and even five; it hardly need be said that if good and perfect blooms are wished for some of these must be taken away. The grower must harden his heart to select the best bud to be fully developed, and take away the remainder; most Roses form about three buds. A blunt stick or a quill are quite sufficient for this purpose in the earlier stage of development; and the sooner it is done, the more will the strength of the plant be thrown into the remaining blooms.

There is one point which oftentimes puzzles the young exhibitor, that is in what class he is to compete. Formerly he had but very little chance if he were a small grower, for he would be sure to find some one who has perhaps ten times as many Rose trees as himself competing against him; in fact, I remember one instance in which one of our largest amateur exhibitors entered in the class for six blooms. This is new impossible, for by the new arrangements of the National Rose Society the place of exhibitors is regulated by the number of plants they grow. So that it rests entirely with the exhibitor as to what class he shall compete in. An unknown correspondent wrote to me the other day, and said he had but fifty Rose trees, and asked in what class he had better exhibit. My reply was, do not attempt anything higher than six; and if there were a class for three I would have advised him to compete in that. No one who has not attempted it, knows the difficulty there is in getting even that small number of blooms in good order for the exhibition day. Most probably, my correspondent will endeavour to have as many varieties as he could without at all considering whether they were reliable or not; he wants to please himself by having many good sorts, whereas if he had only an eye to exhibiting he would find out what were the most trustworthy varieties for the date at which the exhibition was to be held. If it were a late one he would avoid such varieties as Mme. Gabriel le Luizet and John Hopper, whereas if it were an early one he would select these and such other Roses as have the character of being early bloomers. It will thus be seen how very difficult it is for any grower of so small a quantity of trees to obtain suitable blooms for the day of exhibition. We are not likely in the present day, when Rose exhibiting is so much improved, to see such dreadful sights of exhibition boxes and setting up as we used to see. I well remember the indignation of two amateurs whose exhibits were passed over, one having crammed triplets of Roses into a tube only intended for one, thus making it impossible for the judges to ascertain the character of the blooms; and another who in default of moss showed his box with a filling of chopped hay. It is of course sometimes difficult to obtain good green moss, and some exhibitors have an advantage over others by being able to procure it easily, whilst others cut the Gordian-knot by useing dyed moss. The labelling is oftentimes unsatisfactorily done, and therefore amateurs would do well to use the tubes and label-holders invented by Mr. H. Foster of Ashford; they are perfect in their way, and are in almost universal use.

The Season is a Late One.

Now a word as to the season itself. It has been a very varying one so far; we are now within a month of the first show at which the National Society will offer prizes. That cold spell which we have for so many years experienced between May 20 and the end of the month is now upon us, as I write, with its cold winds and slight frosts at night; it must therefore be a backward season, and exhibitors must be in some degree of anxiety as to how their flowers will come out, for when Roses are much retarded by ungenial weather they hardly ever attain to their perfect developement. But our exhibitors are spread over so large a portion of the country that we may reasonably hope that some parts, probably the southern parts of the kingdom, will have an advantage. The experience of last year shows, however, that there are adverse circumstances which it seems impossible to overcome, but "hope on, hope ever" must be our motto. There is much enthusiasm amongst our exhibitors, and I dare say after all our exhibitions will be fairly good; and I think the most sanguine expectations may be indulged in with regard to that to be held at Colchester, even should that at the Crystal Palace not to be so successful as we hope it will be. *Wild Rose, May* 15.

VARIORUM.

Photographing Flowers.—As nearly every person photographs now-a-days, the following hints, taken from a recent issue of the *Boston Herald*, U.S.A., may be acceptable to many of our readers: The photographing of flowers is one of the most difficult and yet fascinating fields of work, especially for those interested in still-life studies. With a very little trouble, one can arrange an ordinary room so as to make very good negatives of flowers. A large window, as high as possible, should be selected—one, if possible, with a working space on each side. The flowers should be arranged 5 or 6 feet from the window. To obtain an even light, one which will light the top as well as the front of the flowers, a screen of cheese-cloth or some other light-coloured material can be fastened to the top of the window, and carried out in the room 3 or 4 feet beyond the flowers. The background to be used should be determined by the colour of the flowers, but black is generally the best. This background should be so placed that no shadows will fall upon it. In this work, one thing above all others which must be sought for is perfect definition, which will demand the use of a small stop, unless a very large, long-focus lens is used. This will prolong the exposure, so that it will generally be found advisable to expose for at least ten minutes. The flowers having been arranged, cardboard reflectors should be placed, one on each side of the flowers, so that they will reflect the light on the deep shadows. This angle can easily be found by moving the cardboards and watching the flowers carefully. The purpose of this is to avoid strong contrasts, and to flatten the light. In focusing, the camera should be set a few inches higher than the flowers, and tilted slightly downward. In photographing white flowers, halation will often assert itself to a greater or less extent, and it may become necessary to use non-halation plates. The development of the plates should always begin with a weak solution, which will bring out the details of the flower construction more thoroughly, and will oftentimes overcome to a considerable extent the obnoxious halation. The printing should be strong, and by a process which will bring out delicate details, and give softness and tone as nearly black and white as possible. The colour of the mount should be selected with reference to the character and tone of the print.

THE WEEK'S WORK.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt Tetbury, Gloucester.

Bedding out.—The season has now advanced so far as to make it safe to plant out in the flower-beds most of the summer occupants. A sketch of the various designs and parterres should ere this have been prepared, which will make it easy work provided each bed is labelled with the name of the plants that will be planted in it, and the mode indicated in which to plant them. Harmony rather than strong contrasts in colours should be aimed at, and plants having flowers of such decided colours as crimson, scarlet, orange, pink, and yellow, go well together, and those with purple and blue flowers, should be planted near plants with flowers or foliage of white and yellow. In setting out the plants do not permit overcrowding, but allow each a sufficient space for the roots to spread and the plant assume its normal shape and size. In mixed beds let the plants employed be such as associate well together in regard to their requirements, in regard to quantity of water and manure, and shade or its opposite. Moreover, mixed beds should be so arranged that the weaker growers are not over-powered and smothered out of existence by stronger growers. One thing of great importance is never to plant anything that is dry at the root, it being a difficult matter, then, to moisten it under-ground. Provided that all of the plants are well moistened at the root previous to being planted, the bed need not be afforded water for a few days. It is not a good practice to leave plants in pots lying on their sides in the sun for several days together awaiting planting, and if they must wait, group them and draw a little soil up to the outer lines.

Dahlias.—Let a position be chosen for these plants where abundant sunlight reaches them, and where they are sheltered somewhat from the wind, the shoots being excessively brittle. In order to have fine blooms, the plants must be afforded a rich and deep soil, spent Mushroom-bed material forming a good sort of manure for them, and in dry weather water will have to be plenteously afforded. Where large roots are planted, the shoots should be reduced to the three strongest, which should be tied separately to a stake or stakes, the ties being loosened occasionally as the stems grow. Since so many of the beautiful forms of the Cactus Dahlia have been raised, the show and fancy varieties are less valued, and there are now splendid varieties of the Cactus type, which produce their blooms on long stems which throw them prominently above the foliage, and among the best of these are Gloriosa, Lady Penzance, Miss Annie Jones, Miss Frances Fell, Mrs. Charles Turner, Vulcan, Starfish, African, Matchless, J. E. Frewer, Keynes' White, and Charles Woodbridge. The Pompon varieties are very pretty, and form fine masses of colour when planted in borders of herbaceous perennials or in beds and borders by themselves; especially nice being the self-coloured varieties. The best varieties to intermingle with shrubs are Juarezi, Glare of the Garden, and Flambeau, these affording a glow of colour in the garden when flowering shrubs are out of bloom, and the effect endures till the tints of autumn begin to show themselves.

Bamboos.—These form graceful clumps of canes and foliage, and are grand additions to the flower-garden and dressed grounds. Bamboos suffer in appearance and in health if much exposed to the colder winds, and should, therefore, not be planted unless thick shelter from trees and bushes is obtainable. B. Métaké, Arundinaria Simoni, A. falcata, Phyllostachys viridi-glaucescens, and P. Henonis rank amongst the hardiest species, and are also the best for planting in low-lying positions. The tenderer species, of which I may mention P. aurea, P. nigra, P. disticha, P. tessellata, and P. pygmæa, will succeed most satisfactorily when planted in sheltered nooks in the grounds, and in the rock-garden if space can be found for them. Arundinarias and Bamboos need a rich, light, well-drained soil with abundance of water in the season of growth. Propagation is by division at the present season, that is, just as they are starting into growth. The leaves of some species of Bamboos fall in the winter months, still, the gardener must not take that as a sign of extinction of life in the stems, and cut them down, as they will again break from the axils of the leaves. Bambusa Fortunei aurea, a very hardy species of low growth, is a pretty plant for the edge of a border or for planting on the rockery. Its rhizomes soon extend, forming a pleasing mass of variegated foliage of a yellowish hue.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

Disbudding Apples and Pears.—Pyramidal and bush-headed Apple and Pear-trees should have their surplus young growths removed about this date, making a commencement with those in the inner parts of the head, with a view to admitting light. Whilst growths are soft, it will suffice to rub them off the branches. It is usual for the leading branches to produce shoots too abundantly, and the most of these should be similarly removed. The Pear-trees bloomed this year most profusely, but the blooms have set unsatisfactorily; and in the case of trees of Beurré Hardy, Conseilier de la Cour, Marie Louise, Bergamot d'Esperen, Duchesse d'Angoulême, Pitmaston Duchess, Doyenné Boussoch, Beurré Superfin, and Beurré d'Anjou, nearly all the blooms dropped. A fair number of fruits seem likely to be retained on the following, viz.—Thompson's, Beurré Diel, Williams' Bon Chrétien, Durondeau, Marie Benoist, Louise Bonne of Jersey, Knight's Monarch, Souvenir du Congrès, and Josephine de Malines. Caterpillars have not been very troublesome on Pear-trees up to the present time, owing probably to the coldness of the weather; still, it will be wise in disbudding the trees to remove all damaged fruits, and squeeze between the finger and thumb all curled-up leaves.

Apple and Pear Cordons require a good deal of disbudding, notwithstanding the fact of "dwarfing" stocks being chosen for supporting them. In doing this operation the gardener should stop the stronger shoots and those most thickly placed first, and rub off the remainder, excepting those to be retained for the formation, later on, of fruit-spurs. These reserved shoots should not be left closer together than 6 inches. If a leading-shoot of a trained tree has reached the top of the wall or fence, or filled the space allotted to it, let it be pinched at the second or third leaf from the commencement of the new growth; but if there is space for further growth let it go on unstopped, but take care that it is trained-in early in the right direction.

The Morello Cherry.—Now that the fruit is set, disbudding may have attention; also pinch back to two or three leaves all foreright shoots if it be thought desirable to let spurs form, and remove all those at the backs of the shoots, and any that are badly placed. Shoots running in the right direction, and those that are readily laid in to cover bare spaces, may be reserved in sufficient number to meet the requirements, and no more, over-crowding being opposed to fruitfulness. The ruling idea is to cut out at the winter pruning much of the old wood, and the previous year's shoots that have borne fruit, and insert the shoots of one year old, thus renewing the youth of the tree. In going over the trees clear off all the remains of fallen blooms and petals, which would otherwise form lurking places for injurious insects, supplementing the work with a douche from the garden-engine. If aphides attack the trees, as they usually do, some soap-suds, a solution of Quassia, or Bentley's Extract, may be put into the engine, using half-a-pint of the latter in two gallons of clear rain-water.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Cymbidium Lowianum.—That this most useful Orchid is best suited by a cool system of culture is abundantly proved by the grand floral display annually produced here under such conditions. The flowers are capable of remaining fresh upon the plants for a long time, and it becomes necessary in the interest of the plants to remove the spikes when they have been in flower five or six weeks. A week or ten days subsequent to the removal of the flowers, those plants requiring larger pots should be treated as follows:—Let the increase in the size of the pots used be considerable; the plants are free-rooting, and it is not desirable to again disturb them until three seasons or so. If the plants cannot be easily removed from their receptacles in the ordinary way, break the pots with a downward stroke of a hammer. Place the ball of roots and soil in the new pot to see how much drainage is needed to bring the plant to the required level. More crocks will be needed around the ball, but they should be worked in with some of the rougher portions of the compost. Fill in with alternate layers of crocks and rough compost until within 3 inches of the rim of the pot, two of which should be filled with compost, and the other left for the convenience of watering. The compost should consist of good, lumpy, yellow loam one part, turfy peat one part, and the remainder of well-rotted farmyard manure, sand, or finely broken crocks, and sphagnum-moss. These ingredients should be used in a moderately dry state, and be pressed firmly together with a thin-edged rammer. Place the plants in a house that has ample means of ventilation, where they are not more than 4 feet from the roof-glass. At the present time the temperature may rise to 70° or more during the hottest part of the day if the top and bottom ventilators be open; but during the night it should recede to about 55°, or lower if natural conditions permit. Fire-heat need only be used when the inside temperature approaches 45°, and a lower temperature even than that will not harm the plants in winter, providing the atmosphere be fairly dry. Plants not needing to be repotted, should be supplied with sufficient water to keep the soil in a moist condition, increasing the supply, and alternating it with weak manure-water as the season advances. Those repotted will require very little water at present, and no manure-water during the present season. On all bright days they may be thoroughly syringed overhead morning and afternoon, the abundance of air given tending to great evaporation.

Cymbidium giganteum, C. grandiflorum, and C. Tracyanum, succeed under the same conditions and treatment, but should be removed to warmer quarters as soon as the flower-spikes appear, their natural flowering season being in the middle of winter.

Cyperorchis elegans, usually known as a Cymbidium, should be repotted if necessary. Excepting that no stable-manure should be given, and considerably less loam, the plant may be treated similarly to the Cymbidiums.

Miscellaneous.—Bletia hyacinthina may now be stood in a sheltered and sunny position out-of-doors, but will still require root-waterings. Thunias, likewise, if the flowers have past, may be hardened off, and removed outside, and stood in the sun to thoroughly ripen their pseudo-bulbs. Pleiones should be afforded weak manure-water, and the leaves occasionally sponged to prevent red-spider.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Cyclamens.—Such plants as were raised from seed last August, which are now in 3-inch pots, should be transferred to 5-inch ones, affording them a compost consisting of two-thirds fibry loam, one-part leaf-soil, silver-sand, and a small quantity of rotten manure. Let the plants be stood on a layer of coal-ashes or fine shingle, near the roof-glass, in a low, moist house or pit, where a night temperature of 55° is maintained, dispensing with artificial heat as soon as that temperature can be secured without its aid. Use the syringe freely both among the pots and overhead; air freely when the plants are established, and afford shade in the middle of the day during bright sunshine. Fumigate the plants upon the first appearance of thrips or greenfly, which should be looked for on the lower surfaces of the leaves. Later, the plants may be shifted into 7-inch or 8-inch pots, according to the size of the plant, and the purposes for which they are required.

Gloxinias and Achimenes.—The earliest batches of these plants will now be coming into flower, and should be assisted by applications of weak manure-water, particularly in the case of Achimenes growing in shallow pans and wire-baskets. The plants should also be afforded a drier and more airy position than was necessary while they were making their growth, a too close and moist an atmosphere causing the flowers to damp-off. Gloxinias may be grown at this season in a cooler temperature than would be advisable earlier in the year; and where space is needed in the stove, plants which are growing freely may be transferred to a shelf in an intermediate-house. The propagation of choice varieties of Gloxinias by means of the leaves may be undertaken at this time, choosing for the purpose the more mature leaves, and after cutting the midrib through in two or three places, peg the leaves down in pans filled with finely-sifted loam and sand in equal proportions. The leaves should then be covered with a bell-glass, and placed in the sun, in the stove, or a warm pit or frame.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Cauliflowers.—Those plants which, having been raised in heat, have been grown under hand-lights and in cold frames, will, in the south, begin now to have useable heads, and the beds should be examined from time to time, and the tips of the leaves bent down, so as to keep the light from the heads. When one has become fit for consumption, cut it from the plant early in the morning, and if not required for immediate use put it in a cool place. The showery weather has been suitable for planting, and the larger plants raised from seed sown in the open may, if space be valuable, be pricked off into nurse-beds, at a distance of 6 inches apart, to be lifted with good balls of earth later on; but if a suitable quarter be vacant, let it be prepared, and set out the plants forthwith. Cauliflowers of the dwarf Erfurt type may be planted at 15 inches apart, the Walcheren and the stronger growing varieties at 2 feet. Before planting draw moderately deep drills, and plant therein; and if clubbing be feared dip the roots in soot-water, and then in a puddle made with soot, clayey loam, and water, to the consistency of thick paint. Another sowing may be made, which will furnish Cauliflowers during the month of October.

Brussels Sprouts.—As the plants become large enough, get them planted in the quarters, in lines and beds. If in contiguous lines, allow a space 2 to 2½ feet from plant to plant; single lines, 2 feet; for the greater the space, the more abundant the crop of sprouts, and the longer time the stem-leaves remain on the plant. Brussels Sprouts succeed in a deep, moderately firm, rich soil.

Peas.—Make an abundant sowing of Marrowfat Peas, this time in trenches. Ne Plus Ultra will be found an excellent variety, but any of the Marrow Peas will answer for this sowing. The last sowing of these kinds should take place from June 10 to the 20th, after which date it is useless to sow any of the taller kinds; but a few rows on a sheltered border of some early varieties may be sown, which, if not cut off by frost, or crippled with mildew, will afford Peas till late in October. Earth up and put sticks to all rows when the plants are 6 inches high, and afford a mulch if the soil be light.

French Beans.—The first sowing being well above the soil, the produce of this sowing will probably be better than that of the earlier sowings, the cold three weeks ago having had an injurious effect on those. Sowings of Beans should be made every fortnight, in order to keep up a full supply of pods. Let advancing rows be moulded up similarly to Peas.

Asparagus.—The beds should be cut over daily, the heads being sorted into first, second, and sprue, and the butt-ends stood in pans containing water. Do not wash Asparagus to free it from grit, as by so doing it soon spoils.

Mint, Tarragon.—Increase the stock by pulling up young pieces having roots, and dibbling them in at a distance of 8 inches apart on prepared beds, and in a few weeks a good supply may be obtained, while the roots will be found excellent for forcing another year. Seeds of Sweet Basil, pot-Marjoram, and other tender herbs, may now be sown in a sunny spot, giving the beds a fine tilth, the seeds being minute.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

Strawberries.—In order to obtain good results, the gardener must afford water almost daily, and in bright weather twice or oftener a day to plants that are stood on shelves near the glass. The size of the fruits may be increased by the use of clear guano-water once a day, or by the use of an artificial manure in powder once a week. If the Strawberry-pots are stood upon a layer of turf with the grassy side reversed, the need to apply water to the plants will be less, while suitable plant-food will be afforded. The varieties James Veitch and Auguste Nicaise, possessing large fruits, should have these thinned to seven or nine on a plant, which should be supported on forks made of Birch twigs above the heads of the leaves, this being seen to in good time. An orchard-house is a very suitable place for the plants at this part of the season, and failing this convenience, a brick-pit may be utilised. Red-spider has given a good deal of trouble this season; but owing to the increase of sunlight, it is now easier to deal with by means of clean water applied regularly twice a day with the syringe till colour shows in the fruits, when it must be discontinued. The latest batch of plants that have set their blooms may be infested with aphides, in which case they should be dipped into an insecticide, or fumigated or vaporised. Vaporising is the more expedient method when the plants are many, and the house or pit is suitable. If but few plants are infested, these may, unless rooted into the turf-layer, be taken into a small house or frame for vaporising or fumigation. An occasional syringing with Quassia-water will avert an attack of aphis by rendering the leaves distasteful to them. If the stock of plants is insufficient to meet the demand, carefully lift young fruiting plants outdoors after affording them water, and having potted them, afford shade, and keep moderately close for a few days.

Young Vines in Pots.—Those Vines which are being prepared for fruiting next year will need frequent and regular attention in the matter of affording water at the root, syringing the foliage, and giving ventilation. Every leaf should be allowed space for full development. When a length of cane of from 6 to 8 feet has been made, the leading point should be nipped out, also the resulting new leader; thus compelling the hitherto dormant bud to break and take the lead. The growth of the laterals must be checked by pinching the new growth to one new leaf. Weakly canes of less than 6 feet should be encouraged to make further growth by affording them once a week water in which Peruvian guano is dissolved at the rate of one ounce to one gallon of water. Farm-yard liquid manure may be used in lieu of guano if diluted to a safe strength, and it may be used alternately with clear water. The degree of syringing should be modified to suit local conditions; in small houses in which red-spider usually puts in an early appearance, syringing at least once a day will benefit the plants; in larger structures with floors and border-surfaces kept well and regularly moistened, syringing may often be dispensed with without risk of any attack from red-spider.

Young Vines raised from eyes this year will be ready for shifting into larger pots, and in the case of Vines to be permanently planted next spring, pots of 9 inches in diameter will be large enough, and the same size will answer for those to be cut back next autumn and grown on another year for fruiting in pots. For planting and inarching purposes, very large pots are not desirable. The inarching of Vines may be performed at any time during the season of rapid growth. A good union can often be effected in one, two, and three-year-old Vines by inarching green shoots. For pot-Vines turfy loam of good quantity, roughly broken, a small proportion of decayed horse-dung, a few half-inch bones, a little artificial Vine-manure, and some burnt refuse, make a capital potting compost. The pots used should be new or quite clean ones; and the soil pressed into them with a moderate degree of firmness, and it should be in a condition neither too wet nor too dry.

The Early Vinery.—The fruit is now ripe or approaching ripeness, and the air should be kept comparatively dry, and constant ventilation afforded by day, more or less in amount in accordance with the weather and the prevailing wind; the admission of much air when an easterly or northerly wind is blowing, soon showing ill-effects in an attack of red-spider. The borders should not be allowed to suffer any lack of moisture. A trifling amount of air may be admitted at night by the top sashes; and, till we get warm weather, mild artificial heat must be furnished. Ventilation by means of the front sashes assists the colouring of the fruit; but it should be given carefully in warm weather, and with slightly warmed pipes—a little may be left on at night with certain advantage in the matter of colouring and bloom. Where syringing is practised during the growing season, this must now be discontinued. If Madresfield Court Muscat occupies a part of the vinery, and it is feared that cracking of the berries will ensue, apply a strawy mulch in order to arrest evaporation from the border. Outside borders are the better for being covered with corrugated iron, or wooden shutters, but in any case afford them enough water. A heavy application of water to a dry border is sure to produce split berries in Madresfield Court Grape, as will also the sun acting suddenly on a humid atmosphere in the early morning. Slight shading will help to minimise this evil where it commonly occurs. If red-spider take possession of the foliage, the only sure remedy is sponging the leaves, although sulphur may be applied to the leaves by means of a distributor.

BOTANICAL WALL-DIAGRAMS. — From the Society for Promoting Christian Knowledge, we have received a specimen of their wall-diagrams intended for class teaching in school-rooms, for which they are well suited, and would be still more so if they were of larger size.

APPOINTMENTS FOR JUNE.

TUESDAY,	June 6	Scottish Horticultural Association Meet. National Amateur Gardeners' Association Meet.
WEDNESDAY,	June 7	Royal Botanic Society, Floral Fête.
FRIDAY,	June 9	Essex Horticultural Show, at Epping (2 days). Royal Botanic Society, Lecture.
SATURDAY,	June 10	—Royal Botanic Society Meet.
TUESDAY,	June 13	Royal Horticultural Society Committees. National Rose Society, Committee Meeting. Royal Horticultural Society of Ireland, Meeting. Cambridge Horticultural Society, Exhibition.
WEDNESDAY,	June 14	Grand Yorkshire Gala at York (3 days). Royal Cornwall Agricultural Show at Launceston (2 days).
THURSDAY,	June 15	—Linnean Society, Meeting.
FRIDAY,	June 16	—Royal Botanic Society, Lecture.
MONDAY,	June 19	Royal Agricultural Society's Show at Maidstone (5 days).
TUESDAY,	June 20	Royal Oxfordshire Horticultural Society's Show.
WEDNESDAY,	June 21	Rose Show at Shanklin, Isle of Wight.
FRIDAY,	June 23	—Royal Botanic Society, Lecture.
SATURDAY,	June 24	Windsor Rose and Horticultural Show. Royal Botanic Society, Meeting.
TUESDAY,	June 27	Royal Horticultural Society Committee (special prizes for Roses).
WEDNESDAY,	June 28	Richmond Horticultural Society, Exhibition. York Florists', Exhibition of Roses. Rose and Horticultural Shows at Bath, Maidstone, Reading, Croydon, and Ryde, I.W. Annual Dinner of the Gardeners' Royal Benevolent Institution.
THURSDAY,	June 29	Royal Horticultural Society of Ireland, Exhibition. Sutton Rose and Horticultural Show. Rose Shows at Canterbury, Eltham, and Norwich.
FRIDAY,	June 30	—Royal Botanic Society, Lecture.

SALES FOR THE ENSUING WEEK.

TUESDAY,	June 6	Sale of Greenhouse and Bedding-plants at Mill Ash Nurseries, Duffield Road, Derby, by order of Mr. F. Lewis, by Protheroe & Morris.
WEDNESDAY,	June 7	Palms, Ferns, Greenhouse-plants, Gladioli, Japanese Lilies, &c., at Protheroe & Morris' Rooms.
FRIDAY,	June 9	Imported and Established Orchids, at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period May 21 to May 27, 1899. Height above sea-level 24 feet.

Remarks.—The weather during the past week has been dull, with strong, cold winds.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—59·7°.

Actual Temperatures:—

London.—*May* 31 (12 P.M.): Max. 75°; Min. 43°.

Provinces.—*May* 31 (6 P.M.): Max. 65°, East Counties; Min. 53°, Aberdeen.

Fine, Warm.

The Temple Show. This great exhibition, which represented the high-water mark of cultivation, opened on Wednesday under the most satisfactory conditions as regards weather. The show itself was of the usual character, little or no alteration being observable in the general arrangements. While we have not observed any very striking novelty, the quality of the exhibits was fully up to if not beyond the average, and many subjects, which merely fill up space without any special purpose beyond advertising the exhibitor, were conspicuous by their absence. The setting-up of the exhibits was generally excellent, though overcrowding was still observable.

As last year, there were no announcements upon unsightly cards that particular exhibits had been grown from Messrs. So and So's seeds or with Messrs. So and So's manures; and cards announcing the name and address of the exhibitor even, were not permitted to exceed 84 square inches. The effect obtained by the imposition of these regulations is altogether satisfactory, for at many exhibitions outside the Royal Horticultural Society, not only is the general view of the show rendered less artistic by the obtrusion of advertisement cards, but some of the exhibits are partially obscured by them.

In consequence of the greater demand made upon the available space each year, and the impossibility of increasing that space, it was found necessary to exclude from this season's show all exhibits of table decorations, bouquets, vases of arranged flowers, and other florists' specialties.

Doubtless, some of the ladies especially have noted the omission of such exhibits with some disappointment, but if anything has to be sacrificed, it would be difficult to suggest the particular items that would please everybody. And it is very essential that new exhibitors of plants, flowers, fruits, and vegetables should be given every encouragement possible.

The collections of hardy shrubs, deciduous and other, were very beautiful, particularly one exhibited by Messrs. Fisher, Son & Sibray. A collection of hardy Bamboos, from Messrs. Veitch, and from Messrs. Paul & Son, Cheshunt, are noticeable in this connection.

In the tents, the exhibits were so numerous and so excellent, that it is difficult to particularise, and the detailed report in another column will furnish the curious reader with ample details. The Begonias of Messrs. T. S. Ware were specially noteworthy; the Roses of Messrs. William Paul & Sons, and of Messrs. Paul & Son of Cheshunt, Mount of Canterbury, and Turner of Slough, attracted the attention of visitors, as also the splendid groups of foliage and flowering plants shown by Messrs. Veitch. The Caladiums from the same exhibitors, and by Messrs. Peed, Laing, and others were also admired. M. Van Waveren, of Haarlem, showed a group of Astilbes, which illustrate the great variety there is now in these beautiful plants. Messrs. Sutton's Nemesias, and Messrs. Carter's Calceolarias are worthy of special notice. The Ghent Azaleas of Messrs. Cuthbert, Russell, and others, formed one of the most brillant attractions of the show, and Messrs. Jackman's Clematis showed what progress is being made in hybridising and selecting. Orchids as usual form one of the leading features of the show, and were bewildering in their numbers and beauty. Continental exhibitors, such as M. Linden, and M. Jules Hye, honoured us with their presence, and indicated the excellence of cultivation and of selection of varieties that long experience has led us to expect.

As to Ferns, it is sufficient to mention the collections of Messrs. Birkenhead, May, and Hill, to show how well these lovely plants were represented.

Fruit and vegetables were excellently shown. Peas in pots, Tomatos, and Asparagus, were remarkably good. Messrs. Rivers showed wonderful fruit-trees in pots, Messrs. Bunyard had a remarkable collection of Apples, and the exhibits of Messrs. McIndoe, Fife, and others, worthily represented British horticulture.

LINNEAN SOCIETY OF LONDON. — May 4, 1899.—Mr. A. D. Michael, F.L.S., Vice-President, in the Chair. Mr. I. H. Burkill exhibited specimens of a Daisy (Bellis perennis), found at Kew, in which the ray of the outer florets was so nearly absent that these consisted of scarcely more than ovary, naked style, and stigma. A paper by Mr. George West on "Variation in Desmids" was read. The Desmidieæ were shown to be morphologically specialised, and to exhibit a marked pattern and symmetry of form, major and minor symmetries being recognisable in many species. Variations in form and symmetry were specially dealt with, and a summary given of all that is known concerning the variation in the cell-contents, and in the conjugation of these plants. Observations were also made on the variability of the pyrenoids and moving corpuscles in the genus Closterium. The author's conclusions were as follows:—(1) The structure of the cell-contents is one of the most constant features exhibited by a species, but one of little classificatory value, owing to the large number of species which possess the same structure and arrangement of the chromatophores. (2) The outward form of the cell, as seen in front view, varies within certain limits, which are usually very small, but which may in exceptional cases be considerable. The form of the vertical view is, as a rule, a more constant feature than the form of the front view. (3) The ornamentation of the cell-wall is relatively constant, being always arranged according to a definite law, which is only transgressed by variations in one or more of the individual component groups which constitute the pattern of arrangement. (4) The prolific growth and rapid division of immense numbers of Desmids have a tendency to produce variations from the typical forms. (5) Slight changes in the conditions of environment cannot effect the characters of a species, unless they act for long periods of time. Some remarks were added on inter-relationships of the Desmidieæ, deduced from a study of their variation, and certain species supposed to possess a close affinity were shown to have arisen along very different lines of evolutionary development. The paper concluded with a general account of the evolution of the genera of Desmids. Critical remarks were made by Mr. A. W. Bennett, F.L.S.

—— The last meeting of the Society was held on Thursday, June 1, at 8 P.M., when the following Papers were read. — Mr. F. N. Williams, F.L.S.: On some Caryophyllaceæ from Sze-chuen, with a note on the recent botanical exploration of that province. Sir John Lubbock, Bart., M.P., F.R.S., F.L.S.: On some Australasian Collembola. Exhibitions.—Mr. W. B. Hemsley, F.R.S., F.L.S.: High-level plants illustrated by the collections made by Sir W. Martin Conway, Mr. Edward Whymper in the Andes, and Dr. Sven Hedin in North Tibet. Mr. Rupert Vallentin, F.L.S.: Lantern-slides and photographs of Sea-Elephant, Macrorhinus leoninus, obtained in Stanley Harbour, Falkland Islands, in February, 1899.

THE QUEEN'S EIGHTIETH BIRTHDAY was celebrated at Carlisle by the planting by the Mayor of a fine specimen of Tsuga Mertensiana, known in many gardens as Abies Albertiana, one of the most

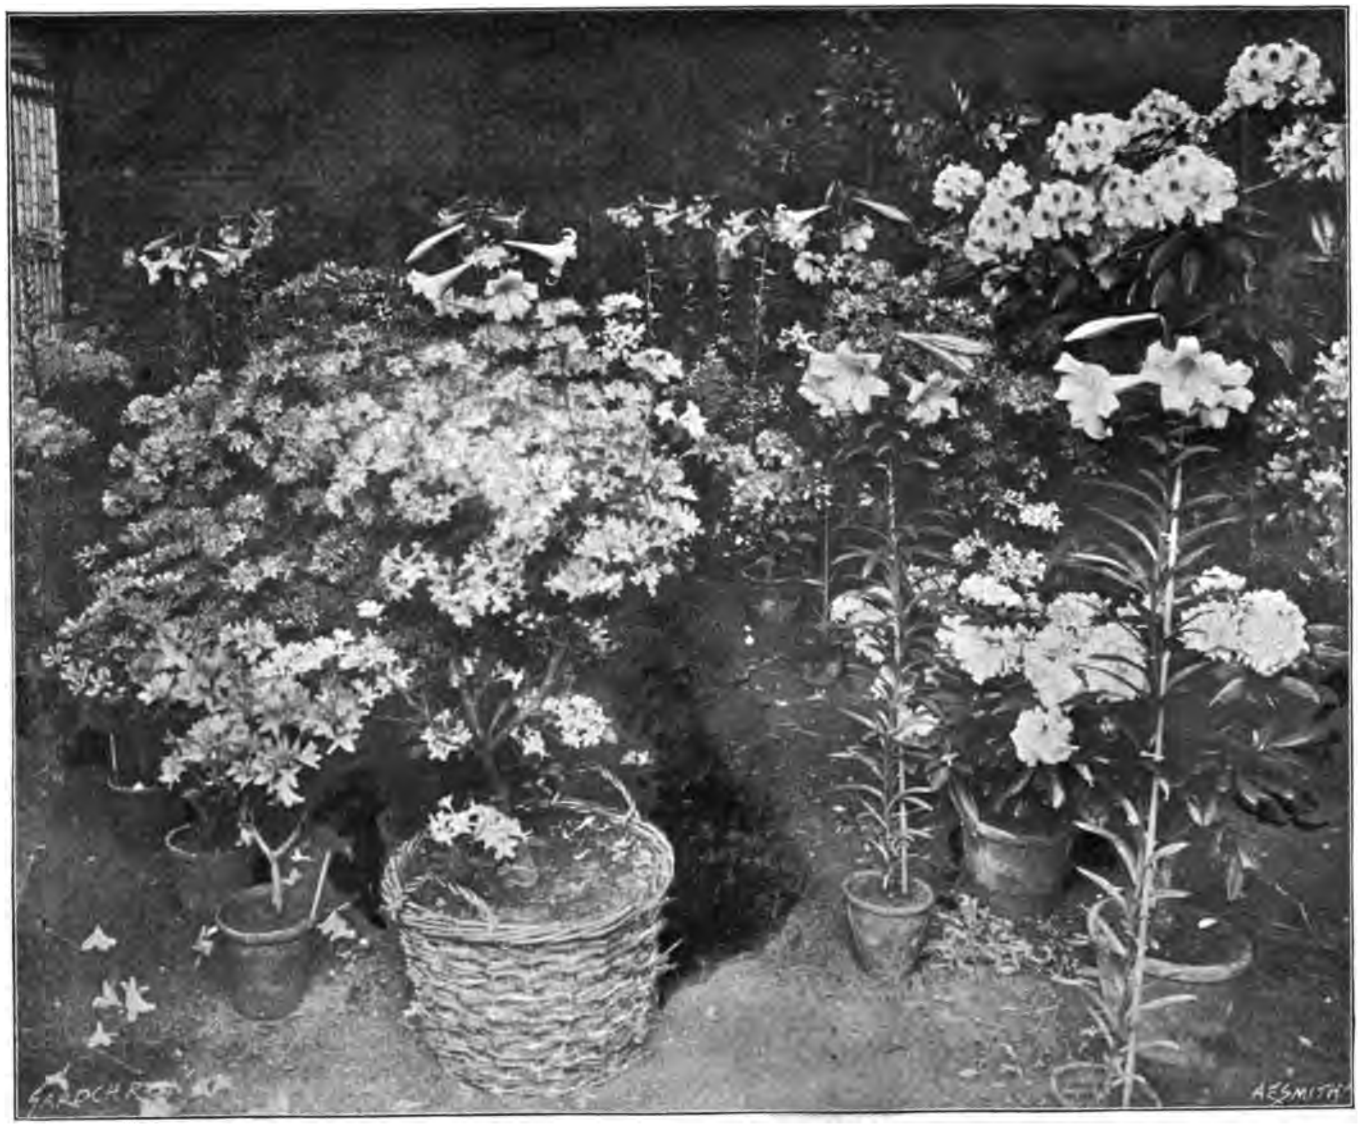
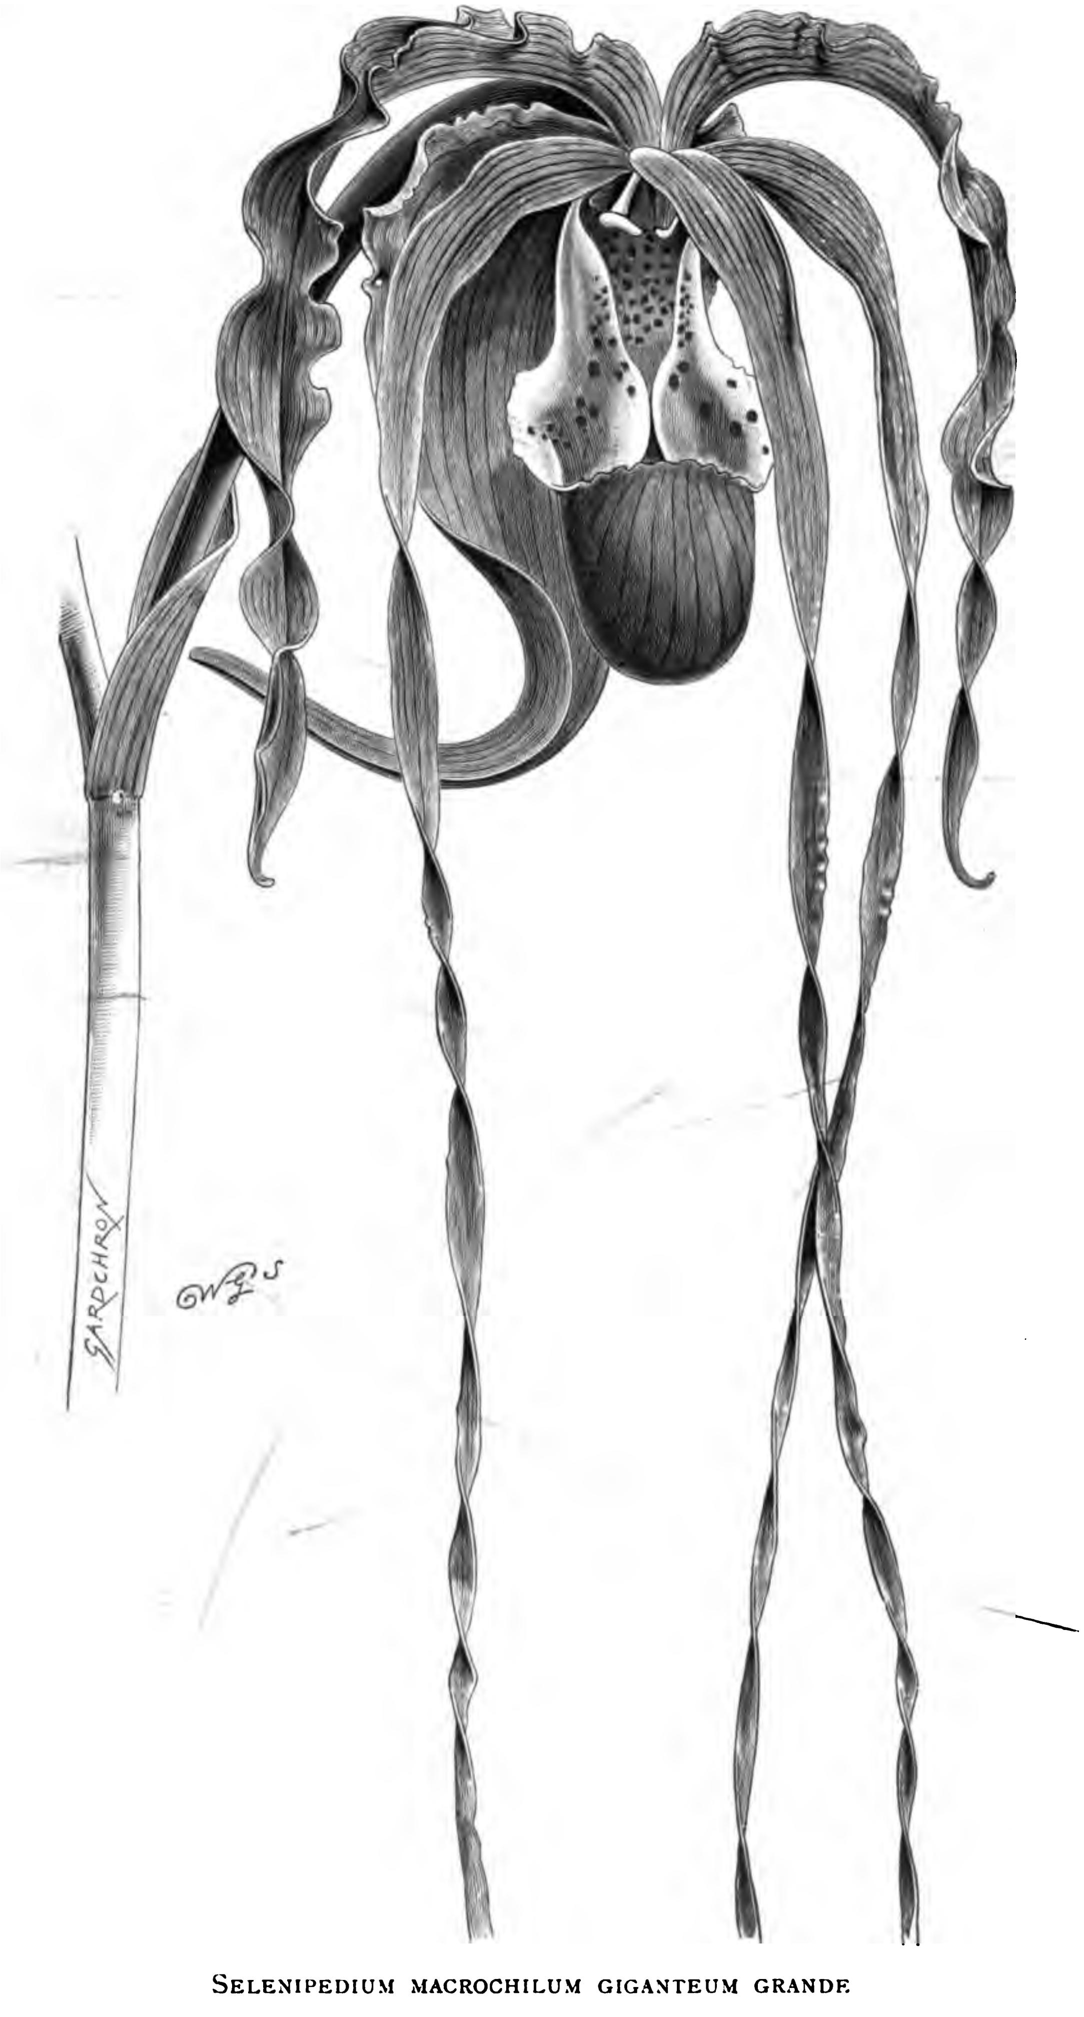
Supplement to The Gardeners' Chronicle," June 3. 1899.



Preparing for the Temple Show.

Supplement to "The Gardeners' Chronicle," June 3, 1899.



Selenipedium macrochilum giganteum grande ornamental of Conifers. The tree was presented by Mr. Watt, who on various other occasions has contributed in like manner to the adornment and wholesomeness of the city. A telegram was sent to Her Majesty notifying the fact of the planting of the tree.

Children's Play-grounds.—A very excellent work is that of providing play-grounds for the youngsters, where the freehold of an "open space" cannot be obtained. There are several such, we believe, in or about the Metropolis, and we are pleased to learn that a deputation from the London Playing Fields Committee, at the Passmore Edwards' Settlement, Tavistock Place, W.C., are invited to discuss the best means of providing extra open-space accommodation for the children of St. Pancras. Mrs. Humphrey Brown intimated that she wished to provide space in order that a thousand children might be able to play cricket and other games. For that purpose she would willingly give £500, and two of her friends a like amount. Steps will be taken at once to utilise this liberal offer—to which we wish all success.

A Conspectus of the Genus Lilium.—To the April number of the *Botanical Gazette* (Chicago), our esteemed correspondent, Professor Waugh, contributes the first part of a monograph of the genus Lilium. Sixty-four species are enumerated. The classification is much the same as that of Baker, given in our columns in 1871, with the addition of a new subgenus, called Pseudo-Martagon, including seven North American species, with paniculate inflorescence, and mostly erect or spreading flowers, funnel-shaped perianth, with segments slightly recurved at the lip, or finally recurved from the middle. Mr. Waugh does not appear to have seen Mr. Elwes' superb monograph —at least, he does not quote the fine illustrations therein given.

Spraying: "How to Spray, when to Spray, and what Pumps to Use."—When taking our inspiration from the United States, we did our best to bring the subject under the notice of our growers. We experienced a great amount of apathy, not only among cultivators, but also among advertisers. It was long before we were able to tell our readers where to get the substances recommended, and where to procure the necessary apparatus, and this in spite of the fact that our Hop-growers had long found out the value of the process. Now we can refer our readers to a trade catalogue issued under the above title by Mr. Cecil Hooper, of Swanley, Kent. We believe that the Strawson Company, Messrs. White, and Messrs. Merryweather also supply spray-pumps.

A National Flower.—Our good cousins on the other side of the Atlantic have not yet decided what flower is to be their national symbol. The matter is discussed not only in the lay press but in the *Transactions of the Massachusetts Horticultural Society*, and as a general result it seems that the only flower which fulfils all the requirements of the case is the Columbine. Some Aster, in which the stars and stripes might with a little "make-believe" be symbolised, would, to our thinking, be more appropriate than the Columbine; but it is not for us to interfere in so personal a matter. How long, we wonder, was it before the Rose was generally adopted as an English emblem?

Jadoo for Tomatos.—Whilst the reports we receive from India and the Colonies are variable in their tenor, the Channel Islands Tomato-growers speak highly of its value for their purposes. It seems to favour the production of roots.

Æcidium Grossulariæ.—A short time since we figured "the cluster-cups" which affect the Gooseberry, but we omitted to state that according to the experiments of Klebahn, this is a form of the same fungus that appears on certain Sedges, and is known under the name of Puccinia Pringsheimiana. The appearance of the two forms is so utterly different, that cultivators may well have doubts as to the correctness of the statement. Nevertheless, it has been proved by infection-experiments in so many cases, that no reasonable doubt can now be entertained. The Puccinia ribis, which grows on the Red-Currant, forms one kind of spore only, the teleutospore, and hence does not occur in two such distinct forms as in the Gooseberry fungus, though a specialised form occurs in the Red-Currant, but not on the Black-Currant. M. Erikson, who has lately published a paper on the subject in the *Revue Générale de Botanique*, tome x., p. 497, recommends that all diseased leaves and berries be burnt in the autumn as far as possible, and that in spring the bushes be sprayed with Bordeaux Mixture, and not the bushes only, but the soil in their immediate vicinity.

Abnormal Pear Blossom.—Mr. Basil has sent us a terminal shoot of a Pear, in which, intermixed with long-stalked leaves, are peduncles bearing green flowers of a peculiar structure. The "Pear" proper is absent, but there are five leafy sepals in a whorl, a number of leafy petals and stamens more or less spirally disposed, and in the centre a secondary flower with five ordinary sepals, as many petals, and several stamens, but no pistils. Such flowers have naturally no interest for the fruit-grower, but they afford valuable evidence to the botanist studying the real nature of the flower.

Presentation to the Rev. F. D. Horner, V.M.H.—On Saturday, May 27, the members of the Bradford Paxton Society paid a visit to the famous Tulip-garden of the Rev. F. D. Horner, Greta House, Burton-in-Lonsdale. The kindness with which they always have been received, and the respect which is entertained for Mr. Horner, led the members to ask his acceptance of a Smoker's Cabinet. On arrival, the party were welcomed by Mr. and Mrs. Horner, the presentation being made by the President, Mr. A. E. Benney, and brief speeches were made by Councillors E. E. Dowson, T. A. Williamson, and H. M. Trotter. Subsequently, an inspection of the garden was made, Mr. Horner explaining the evolutions of the Florist Tulip. Unfortunately, the season has been adverse, and the flowers were not far enough advanced as to show their full beauty.

Henry Shaw Medal, St. Louis, Missouri.—The Director of the Missouri Botanical Garden desires us to call attention to the fact that in June, 1893, the board of trustees of the Garden, founded a gold medal to be known as "The Henry Shaw Medal for the introduction of a valuable plant," and to be awarded each year, when practicable, for a new plant of value for cultivation exhibited in St. Louis, as a part of the premiums or prizes to a flower-show or exhibition provided for in the will of the late Henry Shaw; provided that the judges or other persons making awards at such exhibition shall certify that said medal is "awarded for a plant of decided merit for cultivation, not previously an article of North American commerce, and introduced to such commerce by the exhibitor during the year in which said award is made." Numerous plants worthy of the award of this medal are each year introduced into the American trade, and the undersigned will at any time gladly furnish detailed information to their introducers, as to the time of holding the flower-show at which they may be exhibited in competition for the medal. This year the medal will be offered as a part of the premiums placed in the hands of the St. Louis Florists' Club for award at their Annual Chrysanthemum Show, to be held in St. Louis, November 14 to 18, 1899. *William Trelease, St. Louis, Mo.*

Edinburgh Field Naturalists' Microscopical Society.—The members of this Society had a bryological excursion on Saturday, May 20, to the woods round Corstorphine Hill, under the guidance of Mr. Alister Murray. About forty species were collected, but none of any rarity. Corydalis claviculata was got plentifully, and in flower, at the same station recorded by Greville in the beginning of the century. Carduus heterophyllus was found also in quantity, with the root-leaves fully developed, and this would seem to be a new station for it in the Lothians. The melancholy Thistle is the "Cluas au fheidh" of the Highlanders, which is said by some to have been the original badge of the House of Stuart, instead of the Cotton-Thistle. The party returned by the village of Corstorphine, visiting the old church of St. John the Baptist, which was built in 1429, and the famous "Corstorphine Plane." This tree is a remarkable variety of Acer pseudo platanus, and the last of a double line of Plane-trees that once formed the avenue leading to the old castle of Corstorphine. "Corstorphine Planes" are greatly in demand by nurserymen, their chief characteristic being the striking colour of the young leaves in early spring; they have a rich, glittering yellow, so unlike the usual colour of the leaves of this species that they attract attention from a great distance by the beauty and strangeness of their tint. The tree has also the glamour of tragedy about it, for it was under it on the night of August 26, 1679, that James, Lord Forrester, was killed by his niece, an act for which she was beheaded at the cross of Edinburgh.

West Australia.—Mr. E. J. Scammell has been appointed travelling representative of the Agent-General for West Australia, and lecturer on the condition and resources of the colony. The office of the agency is at 15, Victoria Street, Westminster, S.W.

Abnormal Tulip.—Mr. G. Claridge Druce sends us a curious Tulip. From the side of the old bulb arises, parallel to the main axis, a secondary shoot about 3 cent. long, surrounded at the base by sheathing scales. At its apex it bears a long fleshy sheath, 6 to 7 cent. long, of a rosy-violet colour, split down on one side at the base to expose a thick, ovoid, acute bulbil, and prolonged at the apex into a long decurved point. The colour of this long sheath suggests an analogy with a perianth segment. The enclosed bulbil is terminal, about 25 mill. long, enwrapped by the fleshy sheath. The latter is burst open at the base by the pressure exerted by the growing bulblet. It would seem as if this were a precociously-formed lateral bulb, raised on a stalk, and with sheathing-scales of unusual thickness.

Publications Received.—*My Roses, and how I Grew Them*, by Helen Milman (Mrs. Caldwell Crofton), published by John Lane, Bodley Head, London and New York.—*An Encyclopædia of Gardening*, by T. W. Sanders (London, W. H. & L. Collingridge, Aldersgate Street).—*Landscape Gardening as applied to Home Decoration*, by Samuel T. Maynard (New York, John Wiley & Sons; London, Chapman & Hall).—*Annual Report of the Smithsonian Institution*, to July, 1897 (Washington, Government Printing Office).—*Les Plantes Utiles du Sénégal*, par Le R. P. A. Sébire (Paris, Librairie, J. B. Baillière et Fils, et chez l'Auteur, à Thiés, Sénégal).—The *Surrey Magazine*, May, 1899, edited by James Cassidy (published at 61, High Street, Guildford; High Street, Epsom; and 5, Pilgrim Lane, Ludgate Hill, London), contains an illustrated account of Ham House, and papers on Surrey Cricket and Surrey Reptiles; and last, but not least, the introductory portion of some Notes on Surrey Gardening.—*Travel*, edited by Henry S. Lunn, M.D., April, 1899, with articles on Our World's Cycling Commission; Up the Mackenzie River to the Polar Sea, Iceland; Famous Travellers of To-day, and many other appropriate subjects.—*Information Gazette*, Oxford, June, 1899 (Vol. II., No. 8), with papers on the "Educational System of Queensland," "Rome in Restoration, 1899;" "Agricultural Colleges," &c.—*The West-End* (Norfolk Street, W.C.), May 17.—*Agricultural Gazette of New South Wales*, April; this includes, among many other topics, Notes upon the Cultivation of Onions and Rape in the United States, J. H. Bulkeley; Edible Trees and Shrubs of the West Bogan, R. W. Peacock; and Native Food-plants (Part II.), J. H. Maiden.—*Annual Report on the Botanical Garden, Saint Lucia*, 1898. PLANT PORTRAITS.

ACACIA LONGIFOLIA, VAR. SOPHORÆ, *Revue de l'Horticulture Belge*, May.

ACALYPHA CHANTRIERI, a form with ovate acuminate green leaves, edged with white, *Revue Horticole*, May 1.

AMPELOPSIS GRAEBNERI, apparently a highly-coloured form of the common Virginian Creeper, *Gartenflora*, May 15.

APPLE REINETTE DE CAUX, *Moniteur d'Horticulture*, April 10.

SELENIPEDIUM MACROCHILUM GIGANTEUM GRANDE.

THE illustration in our supplement this week was drawn for us by Mr. Worthington Smith at the meeting of the Royal Horticultural Society on May 16, but we were not fortunate enough to be able to examine the plant at close quarters. It seems as if the dorsal sepal was absent, the anterior one (of two united) is broad at the base, and tapering at the apex into a long point; the two lateral petals are also prolonged into long, twisted, ribbon-like tails; the third petal of this series is the lip, which presents its usual character. Within this outer series there appear to be other three long-tailed segments, which may be representatives of the outer three stamens, which, in Cypripedium, are usually abortive. The column we had no opportunity of inspecting. Whether this interpretation of the flower be correct or not, there is no question as to its ornamental character. The hybrid has as its parents C. grande and S. caudatum Lindeni; and it was shown by Messrs. J. Veitch & Sons, Chelsea.

SOCIETIES.

ROYAL HORTICULTURAL.

THE TEMPLE SHOW.

MAY 31, AND JUNE 1 AND 2.

THE great annual event of the horticultural world in London took place in the Gardens of the Inner Temple, lent as usual by the Benchers with kindly courtesy to the Society. Fortunately, the weather was gloriously fine and warm, and everything went off most satisfactorily, the visitors arriving in great numbers late in the afternoon of the first day. The arrangements made by the officials were so good that there was an entire absence of grumbling, and the thanks of the community are due to the authorities for the smoothness with which the great function was conducted. For a general survey of the display as a whole, we would refer our readers to p. 352.

Among those who visited the show on the first day were H.R.H. The Duke and Duchess of Connaught, Lady Plowden, the Duke and Duchess of Devonshire, Countess of Warwick, and Sir A. Arbuthnot.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), W. H. Young, W. H. Protheroe, H. J. Chapman, De B. Crawshay, T. W. Bond, W. Thompson, G. W. Law-Schofield, W. H. White, C. Winn, A. H. Smee, A. Outram, H. M. Pullett, H. Ballantine, J. T. Gabriel, F. Mason, T. Statter, E. Ashworth, W. Cobb, G. Shorland Ball, E. Hill, F. Sander, H. T. Pitt, W. B. Latham, S. Courtauld, and R. Brooman White. For Awards see separate list.

It is difficult to strike a comparison between the shows of one year and another, but the general opinion was that the show of Orchids staged at the present show was the best which has ever been staged at the Temple, and that experience had taught the exhibitors to make a more effective display with their plants than formerly, all the groups being well arranged, some of them even artistically; an uniform setting of small Maidenhair Ferns, Asparagus plumosus, A. Sprengeri, &c., playing an important part in combining the whole in an effective display.

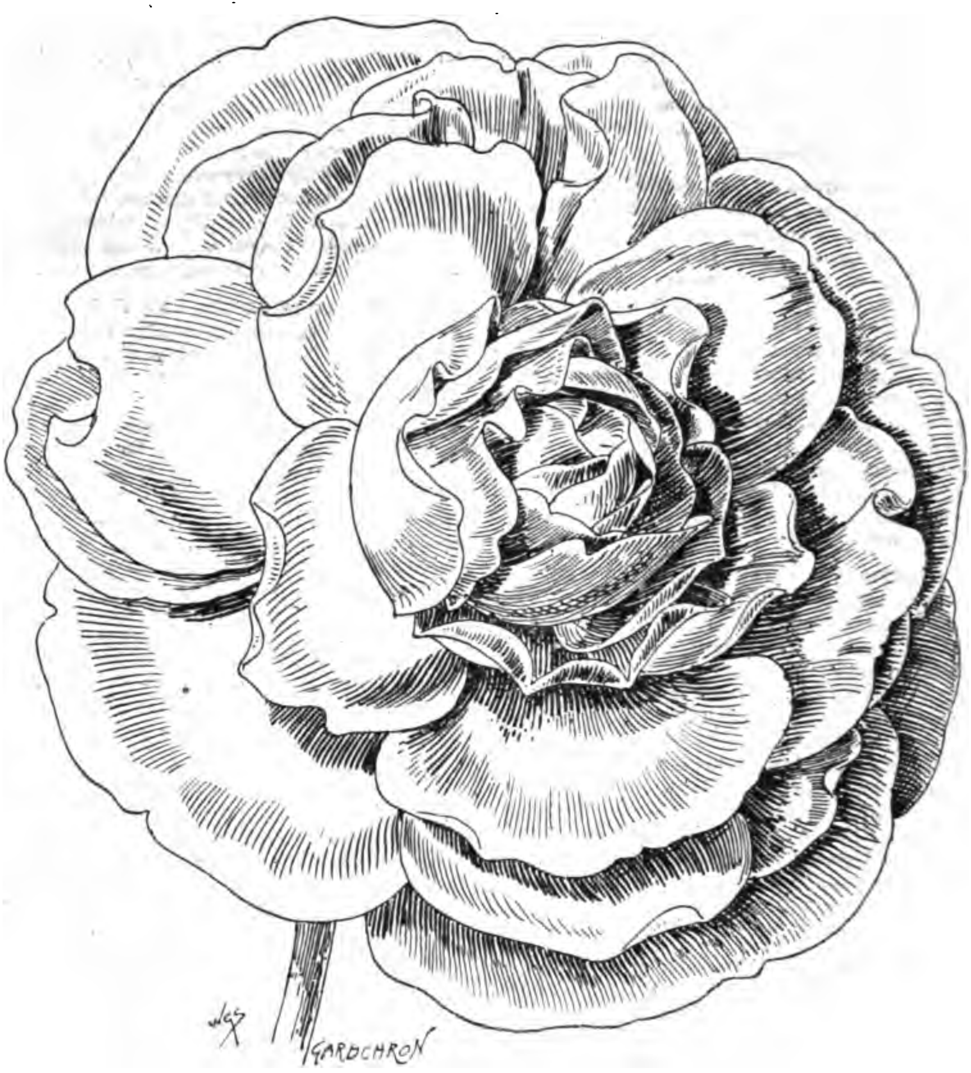

FIG. 126.—DOUBLE BEGONIA "JESSIE POPE": FLOWER OF REAL SIZE; COLOUR PALE PINK.

(Exhibited at the Temple Show by Mr. T. S. Ware. See List of Awards.)

On one side of the central stage Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White), arranged by far the finest group in the show, and perhaps the best which has ever been shown from the Burford Gardens, every plant in it being good, and the whole carefully arranged. Of the taller plants in the back rows, two elegant specimens of Vanda teres, each with about three dozen flowers, showed that fine old Orchid at its best. Arranging well with them were specimens of the white Thunia Marshalliana, with a score or so spikes; the dark rose T. Bensoniæ, with a similar number; the best form of it being T. B. superba, with very large rose-purple flowers. Among others of the taller specimens noted as remarkable were a fine Sobralia macrantha alba, with three snow-white flowers, and several buds; Epidendrum prismatocarpum with nine spikes, E. Wallisii, E. × Endresio-Wallisii, E. × elegantulum leucochilum, E. Schomburgki, and other tall Epidendrums, Oncidiums, &c. The Cattleyas represented were of the best, the varieties of C. Mossiæ including a grand plant of the pure white C. M. Wagneri with eleven flowers, one of the finest specimens of white Cattleya ever produced; C. M. Goossensiana, a charming blush-white flower with the most vivid violet-tinted crimson lip, having a distinct blush-white margin; and other fine forms such as C. M. Reineckiana. The forms of C. Mendeli were equally good, the best perhaps being C. M. burfordiensis, a blush-white flower of perfect form with rosy-crimson lip. The many Cypripediums were remarkable for their handsome foliage, as well as for their fine flowers.

Among them were grand examples of C. × Fowlerianum, "Burford variety;" the best type of C. Lawrenceanum, still one of the most stately species; C. × superciliare, C. × Swanianum superbum, C. Hookerianum Volonteanum, C. × Eleanor, C. granduliferum, &c. Among the many good Odontoglossums were some remarkable forms of O. crispum, both white and blotched forms, the best of the former being O. c, xanthotes, "Burford variety," a pure white, with pale yellow callus; a pretty purple-blotched O. Pescatorei, and good examples of most of the other showy species, many of them having been grown at Burford for many years. Among other remarkable plants were a fine Dendrobium Falconeri, D. nobile nobilius, D. Victoria Regina, some magnificent Miltonia vexillaria, a grand example of Phalænopsis amabilis, Masdevallia Harryana regalis, with twenty-two flowers; M. H. miniata, with forty brilliant blooms; Catasetum × splendens olivaceum, some fine Lælia purpurata, L. × Phœbe, L. Cowani, Lælio-Cattleya × eximia and × Canhamiana, and the charming and rare Cymbidium tigrinum, with twenty-three flowers. A small group in the centre, composed of rare and pretty botanical species, were interesting to the more advanced students of Orchid lore. Among them were Masdevallia O'Brieniana, M. caudata xanthocorys, M. × Gelengiana, M. Wendlandiana, M. hieroglyphica, Polystachya bracteosa, P. Lawrenceana, a little beauty, with pale rose labellum; P. zambesiaca, P. bulbophylloides, Campanemia uliginosa, a tiny plant, with racemes of small white flowers; Saccolabium gemmatum, Restrepia trichoglossa, and a pretty yellow and red species near to R. elegans; Habenaria rhodocheila, Physosiphon Loddigesii, the rare natural hybrid Oncidium × Larkinianum, Bulbophyllum barbigerum, B. elegans, and Ornithocephalus grandiflorus with six spikes.

Next came a group of about twenty grand Odontoglossums, set up with the scarlet Cochlioda Noezliana, sent by W. THOMPSON, Esq., Walton Grange, Stone, Staffs., staged with the usual skill displayed by his gardener, Mr. W. Stevens. All were good, and specially fine were Odontoglossum crispum Arthur Briscoe, a finely-formed, blotched flower; O. × Coradinei Waltonensis, and O. × C. Roeblingi, both pretty, and showing the two extremes of the many forms. O.

triumphans King Alfred, a very finely-shaped flower, with yellowish-white ground colour, blotched with tawny-brown; O. × Andersonianum albo-maculosum, a large, white flower, spotted with reddish-purple; a noble plant of O. luteo-purpureum with two spikes, one of forty-three, and the other of thirteen flowers. All the other plants were also superbly grown, and of fine quality.

Adjoining was a very pretty and tastefully-arranged group, sent by Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young). Elevated at the back, was a fine specimen of Dendrobium thyrsiflorum with ten spikes, and arranged on each side were noble specimens of Cymbidium Lowianum alternating with equally fine large plants of Lælia purpurata, the latter having four very remarkable varieties, viz., L. p. Arthur Wigan, L. p. Russelliana, L. p. Ethel Gray, and L. p. Othello, all very fine and distinct. Other remarkable plants were Phalænopsis Sanderiana "Wigan's variety,' the perfection of pure rose-pink Phalænopsis, and one of the finest in shape of any known Phalænopsis; Cymbidium Devonianum, with four spikes; Cypripedium callosum Sanderæ, with two flowers, C. bellatulum album, C. × Godefroyæ, hybrid, very pretty; Cattleya Skinneri alba of the best type, C. superbum splendens, C. Schilleriana, C. × Lowryana, Lælio-Cattleya × Schilleriana, Odontoglossum crispum, O. × excellens, and O. × elegantius; Maxillaria Sanderiana, Trichopilia tortilis, Spathoglottis Veillardi, Cœlogyne Schilleriana, Dendrobium × polyphlebium, D. × Venus, Epidendrum Wallisii, and the fine old E. falcatum with twelve large flowers and buds; also a fine Odontoglossum Œrstedii, covered with flowers. Continuing, W. A. Gillett, Esq., Fairoak Lodge, Bishopstoke (gr., Mr. E. Carr), staged a nice group, the main features in which were some very fine Cattleya Mossiæ, arranged with good Odontoglossum crispum, O. Pescatorei, and other good Odontoglossums, Oncidiums, &c.; in front being a very neat and praiseworthy specimen of Miltonia Phalænopsis covered with flowers.

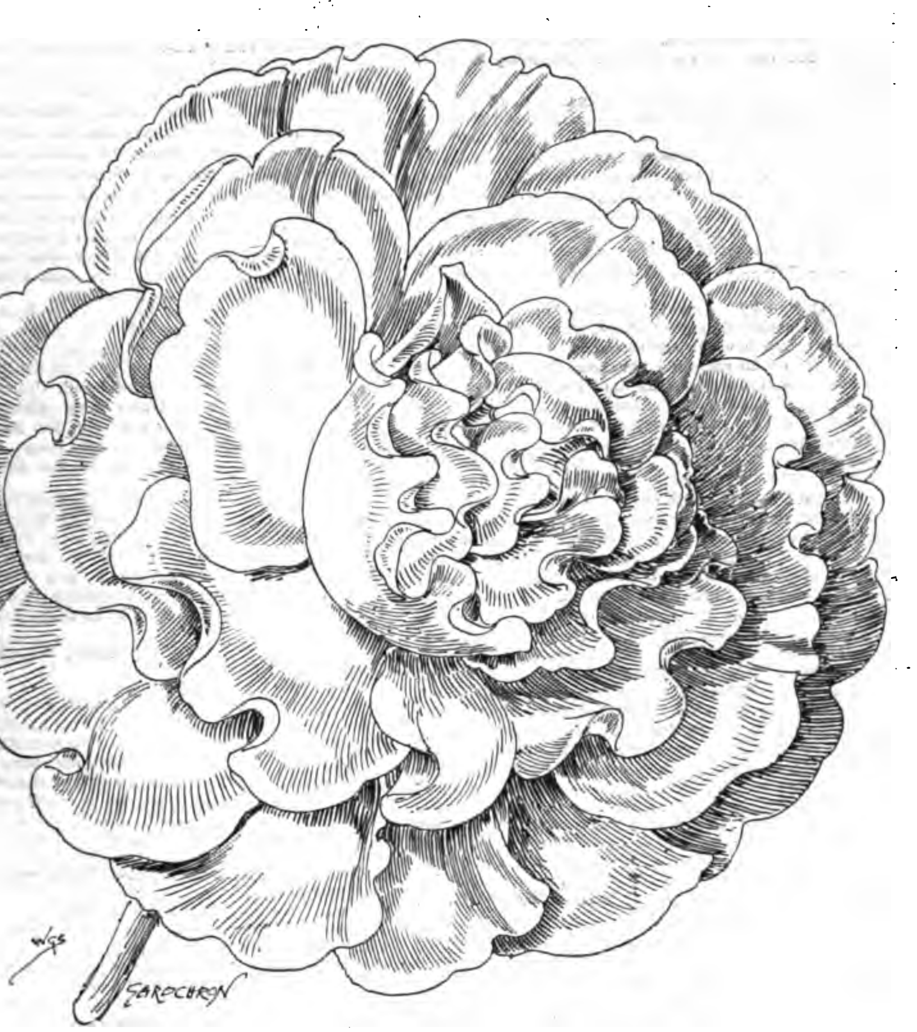

Fig. 127.—DOUBLE WHITE BEGONIA "MARY POPE": REAL SIZE.

(Exhibited at the Temple Show by Mr. T. S. Ware. See p. 368.)

Next Malcolm S. Cooke, Kingston Hill (gr., Mr. Buckle), staged a nice collection of Odontoglossums, including fine O. crispum, O. Halli, O. Pescatorei; also good Miltonia vexillaria, Lælia purpurata, Masdevallias, Cypripediums, &c.

Elevated at the back, Major Joicey, Sunningdale Park, Sunningdale (gr., Mr. Fred. J. Thorne), exhibited two of the best examples of fine cultivation in the show, viz., Luddemannia Lehmanni, with four heavy pendent stripes of orange-coloured flowers, forty to sixty on each raceme, and two more spikes coming; and a grand plant of the yellow-coloured Angulos Cloweaii, with nineteen fine blooms, both securing Cultural Commendation.

J. Rutherford, Esq., M.P., Beardwood, Blackburn, staged a pretty group, made up principally of very remarkably fine forms of Cattleya Mossiæ, all the specimens being well grown and well-flowered. In the centre of the group was a grand new form of Lælio-Cattleya × Aphrodite (C. Mendeli × L. purpurata), named L.-C. × Aphrodite "Ruth." A glorious white flower, the tube of the lip tinged with yellow, and the fine front lobe developed as in C. Mendeli, and exhibiting the rich rose-crimson tint, as in good forms of that species—a charming hybrid. Of the Cattleya Mossiæ, C. M. gloriosa, with its richly-coloured large-lipped flowers was one of the best Mossiæs shown, and the C. M. Wagneri, C. M. Reineckiana, and C. M. Rappartiana, very remarkable white forms.

Walter C. Walker, Esq., Winchmore Hill (gr., Mr. Geo. Cragg), staged an effective collection, made up of good Cattleya Skinneri, C. citrina, and other Cattleyas; Miltonia vexillaria, Odontoglossum Harryanum, Dendrobium Bensoniæ, &c.

Next M. Jules Hye-Leysen, Coupure, Ghent (gr., M. Coen), had a case of very fine Odontoglossums, flowered in his usual admirable manner. The centre of attraction was the noble plant of O. crispum augustum, illustrated in the *Gardeners' Chronicle*, May 23, 1896, and then described as one of the finest of blotched crispums, a character which it well sustains. When illustrated, the figure was said to be an exaggeration, but, on comparison to-day, we are happy to say it is an exact representation. Another remarkable form was O. crispum "Perle du Congo," a blush-tinted flower of peculiar form, the upper sepal having a distinct reddish band up the centre, and the other sepals and petals quaintly spotted, the latter being crimped; several other fine forms of O. crispum were included; also Odontoglossum Halli Lairesseanum, of an uniform greenish-yellow. A fine O. × excellens, Miltonia vexillaria Chelseiensis, Lælio-Cattleya × Hippolita, with many flowers on the spike, and Lælio-Cattleya × Mrs. Albert Hye, one of the finest and richest-coloured forms of L.-C. × Aphrodite (Eudora).

Finishing the arrangements on that side of the tent, came a very pretty arrangement of Orchids, set up with Ferns and foliage-plants, sent by Messrs. Jas. Backhouse & Son of York, remarkable being a very handsomely spotted form of O. crispum, a fine specimen of Sobralia macrantha, and one of S. Amesiæ, Cattleya Mendeli, very fine; Cypripedium bellatulum, Lælia tenebrosa, &c.

On the other side, Messrs. B. S. Williams & Son, Holloway, staged an extensive group, in which were eighteen distinct forms of Cattleya Mossiæ, and nearly as many of C. Mendeli; some fine Oncidium Marshallianum, O. sarcodes, and O. concolor; a fine bit of Odontoglossum crispum, and most of the other showy species, including O. × Edithæ, a pretty hybrid; Calanthe veratrifolia, C. Sanderiana, Miltonia stellata, Cœlogyne Massangeana, Anguloa Clowesii, Dendrobium suavissimum, and other Dendrobiums, Vanda suavis, V. tricolor, V. teres, a fine lot of Lælia purpurata, and a good representative collection of the Cypripediums of the season.

Messrs. Stanley-Mobbs & Ashton, Southgate, had an extensive group, and one of the best arranged, the outline being relieved by two elevated cork-work stands, the pockets of which contained good Odontoglossum crispum, Miltonia vexillaria, and other Orchids, the back-row between the stands being filled in with grand Oncidium Marshallianum, O. sarcodes, O. varicosum, and other elegant species. In this group the forms of Lælia purpurata were fine; a very remarkable white variety (which, however, was not perfectly developed), named L. p. Ashtoni, and in the Cattleyas, C. Mossiæ Mrs. C. H. Feilling, a very richly-coloured variety, of perfect form, was the best. C. Mendeli "Constance," a pretty white form was remarkable, and noteworthy were Epidendrum hastatum, Cypripedium "Gertrude Hollington," and some remarkably fine Lælia tenebrosa.

Mr. Jas. Cypher, Cheltenham, had an extensive group replete with good things, the background carried up effectively with Oncidium Marshallianum, O. sarcodes, O. ampliatum, Epidendrum radicans, E. × O'Brienianum, and other elegant species. The forms of Lælia purpurata and the Cattleyas were specially good.

Messrs. Charlesworth & Co., Heaton, Bradford, staged an excellent group in which the strain of Odontoglossum crispum said to come from a new district, was remarkable, some of them showing excellent and distinct features. Among the best Cattleya Mossiæ were C. M. Reineckiana and C. M. aurea magnifica, and the varieties of Lælia purpurata gave as the best L. p. atro-rubens, L. p. Russelliana maxima, and L. p. fulgens, all good. Other good things in this group were Cypripedium × Gertrude Hollington; the curious Lælia × cinnabrosa; Epi-Lælia × Heatonensis (L. cinnabarina × E. × O'Brieniana); Epi-Lælia × radico-purpurata; Vanda teres gigantea; Odontoglossum × Adrianæ; Miltonia vexillaria Empress Augusta Victoria; Lælio-Cattleya × Hippolyta, of specially bright colour; a fine strain of Cattleya Schilleriana, Oncidium phymatochilum, Masdevallia × Courtauldiana, and other Masdevallias.

Messrs. Hugh Low & Co., Enfield, well furnished the remainder of the centre stage, with one of the best and best-arranged groups they have ever exhibited, and containing all important plants, and no ordinary small "padding." Cattleya Mossiæ "Beauty of Bush Hill," was a truly magnificent richly-coloured, large flower, exhibiting a very extraordinary veining on the sepals and petals, and a peculiar rose-purple feather up the petals; a remarkable exhibit. The other forms of C. Mossiæ were of the best strain; C. M. Wagneri, Low's variety, of a peculiar white, with cowslip-yellow disc. The fine strain of Cattleya Mendeli, culminated in C. M. Perfection, well worthy of its name, blush-white, with ruby-crimson lip, and among the many specimens of Oncidium ampliatum, was O. a. citrinum, totally different in colour to the type. Lælia purpurata in this group were also good, and in it were fine Odontoglossums and Cypripediums, &c.

In the next tent, Messrs. F. Sander & Co., of St. Albans and Bruges, staged a grand display, having a table some 60 feet in length, well displaying their grand strain of Odontoglossum crispum, which certainly have an uniformly fine character in large well-shaped blooms, prolific in heavily blotched forms. The finest example of the pure white form of this strain was enclosed in a glass case with some ornamental foliage, and bore a grand spike of large flowers of the O. c. Duchess type, but superior to that one. Along the table were noted small groups of selected hybrids of this strain, also excellent forms of O. × Wilckeanum, O. × Andersonianum, and O. × Ruckerianum, some of them being profusely and others sparsely spotted. Selecting only the most remarkable plants, we noted a very handsome form of Sophro-Lælia × Marriotti with clear chrome-yellow flowers; a Sophro-Cattleya between S. grandiflora and C. Acklandiæ, with very distinct and pretty bright red flowers; a new hybrid between Cattleya Mossiæ and Lælia tenebrosa, with very handsome flowers of the form of those of L. tenebrosa, and colours of C. Mossiæ; a fine strain of Cattleya Mossiæ, one of the plants having six flowers on a spike, a number perhaps not previously attained; a batch of the pretty Dendrobium atroviolaceum, the noble Miltonia × Bleuana splendens, a fine specimen of Cœlogyne Dayana, with about fifty spikes; the favourite Cypripedium callosum Sanderæ, and the pretty and still not common C. Sanderianum, with four flowers on a spike; C. × conco-bellatulum, and C. × barbato-bellatulum; the remarkable Maxillaria Mooreana, with quaint, large dark green flower; good good forms of Odontoglossum × Adrianæ, a fine plant of Epiphronitis × Veitchi, the singular Bulbophyllum barbigerum, Oncidium superbiens, a very large form of Odontoglossum maculatum, Lælio-Cattleya × Hippolyta, Dendrobium densiflorum Schroderi, D. Goldiei, and some superb forms of Miltonia vexillaria, &c.

Ludwig Mond, Esq., The Poplars, Avenue Road, St.

John's Wood (gr., Mr. J. O. Clark), staged a pretty and effectively-arranged group, to which the varieties of Odontoglossum citrosmum gave character. The largest plant bore four fine spikes, making it an effective centre to the group. Some excellent Odontoglossum crispum, O. Halli, and other Odontoglossums, Dendrobium Devonianum, and fine Cattleyas and Lælias, all arranged to show to the best advantage, were remarked.

Messrs. Linden, Brussels, had a large group, remarkable for the bewildering variations of Odontoglossums, among which it is difficult to describe where species end and varieties begin. Prominent were the fine forms of O. × Adrianæ, two very fine ones being O. × Adrianæ tigrinum, and O. × Argus; and associated with them was a very peculiar hybrid, with prettily-spotted flowers, probably between O. Hunnewellianum and O. odoratum. Among the large collection of forms of Odontoglossum crispum, both white and spotted, O. c. Miss Linden, a prettily-formed, heavily-blotched flower, was noted as being the best; O. c. "The Baby," was a grand flower, with large purple blotch in each segment. Among other specially noteworthy varieties were O. Pescatorei Miss Otelet, a very handsome bloom; O. × Cawenbergi, very showy; O. triumphans "Golden King," a bloom of a clear tawny yellowish hue; O. × cirrho-Halli, O. sceptrum nobilius, Miltonia vexillaria Lindeniæ, a noble variety, with very large flowers, attractively veined with rose-pink; M. v. Jupiter, of a delicate rose-pink; and a number of very singular-looking forms of O. × Wilckeanum and O. × Andersonianum.

H. T. Pitt, Esq., Stamford Hill (gr., Mr. T. Thurgood), showed Cattleya intermedia, "Rosslyn variety," which may be described as a blush-white C. i. Parthenia—very pretty.

Walter Cobb, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes), showed Miltonia vexillaria, "Dulcote variety," the prettiest bright dark rose form yet exhibited. Captain G. W. Law-Schofield, New-Hall-Hey, Rawtenstall (gr., Mr. Shill), showed Lælia purpurata "Annie Louise," a beautiful, finely-coloured flower with petals handsomely veined rose-purple.

Thos. Statter, Esq., Manchester (gr., Mr. Johnson), showed as Lælia purpurata "Statteriana" a similar variety; also the blue Dendrobium Victoria Regina. T. B. Haywood, Esq., Reigate (gr., Mr. C. J. Salter), showed Lælia purpurata "Mrs. Haywood," and Cattleya Mossiæ "Ajax," both good. A. Warburton, Esq., Vine House, Haslingden (gr., Mr. Lofthouse) sent Lælia cinnabrosa. M. Jules Ragot showed Lælia × Ragotiana (grandis × cinnabarina), with narrow orange-coloured flowers, several on a spike. C. L. N. Ingram, Esq. (gr., Mr. F. W. Bond), showed Lælio-Cattleya × Amazone (C. maxima × L. purpurata), a pretty light flower, and L. purpurata fulgens.

Floral Committee.

Present: Edward Mawley, Esq. (Chairman), and Messrs. C. J. Salter, H. B. May, S. A. de Graaff, Chas. Jeffries, J. W. Barr, Chas. T. Druery, R. Dean, C. Blick, Herbert J. Cutbush, John Laing, J. F. McLeod, E. Molyneux, Edwin Beckett, J. H. Fitt, E. T. Cook, Jas. Walker, W. Howe, D. B. Crane, J. Jennings, and R. Wilson Ker.

GROUPS.

In the tent which crosses the big one, containing Orchids, &c., in the middle of it, Messrs. W. Fromow & Sons, Sutton Court Nursery, Chiswick, put up a group of Japanese Acers, in nearly all the known varieties, as small plants, varying from 1½ to 5½ feet. A variety named sanguineum variegatum, which was shown only in small examples, was noted as remarkably attractive in tint, which in the young leaves is vivid-crimson and red-purple, the youngest ones being entirely of crimson; A. palmatum variegatum, A. involutum variegatum, A. palmatum roseo-marginatum, A. p. laciniatum, A. japonicum aureum, are the more remarkable in leaf tints, or in the form of the leaf. The group was agreeably set off by plants of the Bermuda Lily.

Messrs. Cripps & Sons, Nurserymen, Tunbridge Wells, had in the same tent a group of Acers, older examples of good varieties, but not containing novelties; many of the varieties showed their value as decorative plants for the cold conservatory, or as groups in the open, sunk in the turf or otherwise displayed.

Mr. J. Russell, Richmond Nurseries, Surrey, placed a group of Japanese Acers in considerable variety out-of-doors. Among the more remarkable, were the pretty Beech with a rose-tinted margin to the leaf (Fagus tricolor), the purple leaved Birch, silver variegated Sweet Chestnut, a handsome variety; a variegated Sycamore, variegated Ivies, with small and with large leaves; Tree-Ivies, made so by grafting, such as Hedera arborea dentata and others. One of his beds was filled with plants of Viburnum Opulus macrocephalum, and V. plicatum, one of the best, most abundantly flowered. The white and green-leaved Eurya japonica latifolia variegata was used effectively for an edging to the beds. The Japanese Viburnums are particularly nice as wall plants.

Messrs. Fisher, Son & Sibray, Royal Nurseries, Handsworth, Sheffield, had planted out a very extensive group of "picture-trees and shrubs," including the finest of the Japanese Acers—A. Negundo foliis variegatis, A. japonicum aureum, Andromeda japonica variegata, Quercus concordia, the yellow-foliaged Oak; Cupressus macrocarpa lutea, a variety that keeps its colour in age; Tree-Ivies in variety, which make nice stuff for facing shrubberies, and filling beds on the grass. These were shown in green and variegated forms; besides these were Hedera canariensis Crippsii, H. spectabilis, Silver Gem, Golden-blotched, &c. We remarked Ilex Wilsoni, established plants of which bear leaves bigger than those of Shepperdi; and not like that, it is a berry-bearing plant (First-class Certificate); and of Larix Kæmpferi, the Chinese Larch, a nice example in a pot, was shown.

L'Horticole Coloniale, Ltd., Brussels, General Director M. Lucien Linden, showed a group consisting of Hydrangea Hortensia Mariesii, small plants, with fine heads of bloom; H. Hortensia, with palest lilac flowers; H. paniculata, a well-flowered tall standard; Philadelphus Lemoinei Gerbe de Neige; Olearia stellulata, with dense cylindrical heads of white flowers, larger than those of the well-known O. Haasti. The group contained, besides these, Ghent Azaleas, Azalea mollis × sinensis N. Beets, flowers yellow and orange-crimson, a very showy thing; A. mollis albicans, with cream-coloured flowers; A. m. × sinensis Dr. Pasteur, with large corymbs of a soft orange colour; A. hybrida fl.-pl. Freya, a flower with a pale yellow and pink centre, &c.

In the big tent, Messrs. W. Cutbush & Son, Highgate and Barnet, staged a very extensive group, of which pink Carnations Souvenir de la Malmaison formed the middle groundwork, dwarf plants, possessing good blooms; isolated round groups of mixed varieties of Carnations and of Richardia Elliottiana stood prominently in the front, with a margin to the whole of Adiantums. The rear of the group consisted of Palms and Bamboos, fronted by numbers of Rose Crimson Rambler, Hoteia astilboides, and Mollis Azaleas in some variety. The whole was effective, as consisting of small plants.

Messrs. Geo. Jackman & Son, nurserymen, of Woking, Surrey, had a fine exhibit of large, globular-trained plants of the new hardy Clematis coccinea varieties, or rather hybrids with that species. The flowers have much similarity as regards shape, all being rather less closed, as in C. coccinea, some, indeed, spreading considerably; and the colours range from palest flesh, through pink, to purple of various shades. We think that these crosses form pretty decorative plants, not offending by reason of gaudiness or great size of blossoms. A few cut flowers of C. coccinea were shown for comparison sake.

An equal place of honour at the end of the tent was taken by Mr. W. Iceton, Granard Nursery, Putney, with a miscellaneous group, in which Araucarea excelsa, various Palms, Acer Negundo foliis variegatis, Bamboos, Dracæna Doucetti, Bermuda Lilies, Hydrangeas, Caladiums, Ericas, some very fine Lily of the Valley, a specialty of the nursery; and Asparagus plumosus formed the greater proportion of the plants shown.

Messrs. Richard Smith & Co., Worcester, presented their annual display of Clematis in pots; better bloomed, we thought, than ever. Where all was so excellent in variety, and culture so good, it seems invidious to name any one variety, still the varieties Sensation, Lawsoniana, Excelsior, Gloire de St. Julien, Anderson Henry, purpurea elegans, Grand Duchess, and Lord Nevill, would please the most exacting amateur-gardener. The group consisted of about a score of plants, spherical in form, and from 3 to 5 feet high.

A telling group of stove decorative plants, in which Anthuriums and Alocasias, with remarkably fine foliage, formed the main feature, was contributed by Messrs. Wills & Segar, florists, Onslow Place, South Kensington. We noted excellent examples of the following Anthuriums, viz., crystallinum, very perfect leaves; and Veitchi; and of Alocasias there were argyrea, with boldly-banded leaves; Sanderiana, Thibautiana, with light green veins and ribs, the intervening spaces being of a dark moss-green tint; Mortfontainensis, Lowii grandis, and metallica. Other plants in the group consisted of nine Nidularium fulgens, the glowing tint of the central leaves very telling; Phrynium variegatum, Dracæna Godseffiana, D. Goldieana, a fine piece of this difficult plant; Dieffenbachia Bausei; and of Palms standing at the back, were Martinezia Caryotifolia, Stevensonia grandifolia, Verschaffeltia splendens, interspread over all being Crotons, Marantas, Bamboos, &c.

One of the showiest and choicest groups consisting of flowering subjects, was that shown by Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, King's Road, Chelsea. We noted plants of hybrid Azalea mollis in much variety, Lemoine's Philadelphus Boule d'Argent, which has double flowers, Viburnum macrocephalum, Andromeda speciosa Cassinefolia, Cytisus scoparius aureo-variegatus, with white mealiness on the foliage; Hydrangea Hortensia Maresei (see fig. in supplement), Rhododendron hybridum, Prometheus and John Waterer, to give strong masses of bright colour; Lilac Mme. Lemoine, with small spikes of pure white flowers, Alstromeria pelegrina alba, Wistaria sinensis, as standards, Eremurus robustus, and E. r. Elwesianus, E. himalaicus, Hydrangea paniculata var. grandiflora, as standards, and quite effective as such. The back part consisted of Bamboos, and the front of small plants of Japanese Acers.

Messrs. Fisher, Son, & Sibray, showed a mixed group of good varieties of Lælia purpurata, Anthurium Scherzerianum, Handsworth variety; A. Andreanum atro-sanguineum, Alocasia argyrea, examples of Panax and Aralias, including a large one of A. pulchra; Dracæna Doucetti, Asparagus procumbens, small Palms, Azalea Miss Buiste, a small white-flowered, very floriferous variety; Cypripediums, Bertolonias, and Sonerilas.

ROSES.

There were rather more of these than usual, and in most cases the quality was beyond the average; but the excessive heat in the tents soon caused the best flowers to lose their freshness. There was little to choose between the groups of Messrs. W. Paul & Son, Messrs. G. Paul & Son, and Mr. C. Turner, all of which were first-rate, and well set up. H. P. "Tennyson," from Waltham Cross, is evidently a grand new Rose. The habit is good; flowers large and full, and of a clearer colour than Lady Mary Fitzwilliam. Empress Alexandra of Russia was also in good form, and certainly it stands out as one of the most distinct Roses we have. The peculiar shades of salmon and bronzy-red were most taking. We noticed in this group the climbing form of Mrs. W. J. Grant. Like most climbing sports, this is not so good as the normal variety. Clio, Madame Abel Chatenay, and Crimson Queen, were among the best cut blooms, occupying ten large boxes. All of the plants were good, especially Marquise de Litta, Souvenir du Rosieriste, Gounod, Spenser, and Souvenir de Madame E. Verdier. The last named will run K. A. Victoria very close when better known. A comparatively new variety, named Souvenir de President Carnot, is one of the best soft salmon flesh Roses we have. This was one of the best exhibits we have seen.

Mr. C. Turner, Slough, did not show any cut flowers this year, but had a grand group of plants that were well grown, and set up with great taste. Here again Souvenir de E. Verdier and Caroline Testout were most noticeable, while it is almost superfluous to add that Crimson Rambler was very prominent. Messrs. G. Paul & Son, Cheshunt, exhibited some good standards and dwarfs. Psyche, a new semi-double of soft pink shades is showy, and likely to prove a good companion to Crimson Rambler, which it resembles in growth and in the form of the truss. Dawn, another new Rose from Cheshunt, is also good; this is semi-double, and a very bright flesh-pink. Elsie Fugier and Madame de Watteville are always well shown by Messrs. Paul & Son; nor must Carmine Pillar, with its bright carmine blossoms, be omitted.

A group of plants, and eight large boxes of cut Roses, came from Messrs. Rumsey & Son, Waltham Cross, but they were not of the same quality as those already mentioned.

A very bright lot of small plants came from Mr. John Russell, Richmond Nursery, Richmond.

A new Tea Rose, named Sunrise, came from Mr. G. W. Piper, The Nurseries, Uckfield, who staged six of "The Princess" stands, in the same style as was recently seen at the Drill Hall Meetings. It is one of the most distinct Roses we have, and its perfume was remarked by all. Unfortunately, the great heat caused the flowers to droop quickly. Probably this is the most distinct new Rose of the year, both the colouring and deep bronzy foliage being unique, and attracting considerable attention. It was figured in our issue for May 20.

Those who have attended the Temple Show during the past few years will remember the grand cut Roses from Mr. G. Mount, Canterbury, and who this year staged quite 300 blooms of perfect form; Mrs. W. J. Grant, Bridesmaid, Catherine Mermet, Clio, La France, and Caroline Testout were superb. Mr. Mount cuts his flowers with no niggardly hand, and many of those staged had stems fully 2 feet in length.

There was a scarcity of new Roses, Tennyson, Sunrise, Dawn, and Psyche being the best.

CACTACEOUS PLANTS.

Messrs. Jas. Veitch & Sons, Royal Exotic Nurseries, King's Road, Chelsea, again made a large exhibit of Phyllocacti in bloom. In *Gardeners' Chronicle*, June 4, 1898, we gave a capital illustration of the group exhibited last year. Awards of Merit were recommended to three varieties on the present occasion, and others of remarkable beauty were Ursula, orange-red in colour; Marsus, distinct pink; Plato, deep crimson; Hecla, Cooperi, white; Favourite, pink; La Belle, white; and many others. There were upwards of 500 plants.

HIPPEASTRUMS.

Captain Holford, Westonbirt House, Tetbury (gr., Mr. Chapman), exhibited one half-dozen of his marvellous Hippeastrums. Flying Fox had inverse flowers of deep crimson; Desmond is a very light-coloured flower of compact imbricate form, lined in places with rich crimson; Holocaust is a bright flower, of large size, somewhat spreading, scarlet, with considerable white in the throat; Templar, of the type of Desmond, but the petals are more pointed; The Czar is after the style of Flying Fox, but in colour is very much deeper. Messrs. Paul & Sons also showed some fine Hippeastrums.

CANNAS.

Messrs. H. Cannell & Sons, Swanley, Kent, made an exhibit of Cannas in the magnificent manner we have become accustomed to expect from Swanley. The collection included the very best of the new Continental "Gladiolus-like" varieties, and the cultivation given the plants enabled one to see them in a dwarf and vigorous condition. Some of the more distinct and noteworthy in the group staged were aurea, pure yellow; Duchess of York, yellow, spotted with red; Aurore, Madame Pichon, Burbank, one of the very large but rather flimsy flowers; the well-known Queen Charlotte, Duchess of York, a richly spotted variety; Comte de Bouchard, another fine variety of a similar type; Madame Crozy, Lawrence D. Anthony Crozy, Leon Vassilier, Robert Christie, &c.

BEGONIAS.

The tuberous-rooted Begonias formed a very bright feature in tent No. 4. There were several large trade displays, composed of abundantly flowered plants.

Mr. Thos. S. Ware (Ltd.), Hale Farm Nurseries, Tottenham, made one of the grandest displays with tuberous-rooted Begonias ever seen at the Temple Show. Almost all of the varieties shown were double-flowering ones, and two of these were sketched by our artist on the first day of the exhibition.

In addition to the four splendid varieties described under

"Awards," there were Jessie Pope, a flower of very remarkable form and colour, very suggestive of a first class flower of Souvenir de la Malmaison Carnation. The petals have enormous substance and breadth, and the margins are uncommonly wavy. The exact size of the flower and its characteristic form may be seen on reference to fig. 126. In colour it is pale salmon pink; as shown the plant has a perfect habit except that the weight of the blooms renders staking a necessity. The foliage is of moderate size and deep green in colour. The other variety is Mary Pope, a pure white flower. Other fine varieties in this exhibit were Pride of Kent, carmine with whitish centre; Miss Alice Beer, bright carmine, with a few white spots sparsely spread over the petals; Prima Donna, salmon scarlet, very large flower, lighter in colour towards centre; Duke of York, intense crimson, moderate in size; Sylvia, a delightful clear rose colour; Mrs. Dunbar Wood, pure white, very wavy in outline; Golden Queen of England, rich yellow; Her Majesty, pure white; Duchess of Devonshire, pink; Miss Barbara Ray, coppery red. The few singles included were good, but not of so noteworthy a character as the doubles, which will be remembered as one of the distinguishing features of this show.

Mr. H. J. Jones, Ryecroft Nursery, Hither Green, London, S.E., had a group of Begonias in which the single varieties were the more fully represented, and the plants were interspersed with Adiantum and other ferns. Some of the best varieties in the stand were Mrs. T. Lunt, rich rose colour; Mrs. Beerbohm Tree, white; May Mauser, white with rose margins; Admiration, deep reddish-yellow; Sunlight, yellow; and Hero of Omdurman, scarlet, &c.

Messrs. Jno. Laing & Sons, Stanstead Park Nurseries, London, S.E., had a very carefully arranged group of double and single-flowered varieties, and neither section preponderated. The exhibit was very closely packed, like all the others, and a few of the varieties were named, and of doubles we noticed Picotee, Lady Rothschild, rich apricot colour; The Queen, white; Duke of Fife, a magenta shade of carmine; Lady E. Spencer Churchill, a picotee type of flower; and Duchess of Sutherland, pure white. Messrs. Laing have exhibited Begonias with such success for so long a time, that the excellence of their strain is well known.

Messrs. H. Cannell & Sons between their exhibits of Gloxinias and Cannas had also a pretty group of Begonias, including single and double flowering varieties in about equal proportions. Very pretty doubles were Lady Camden, rich salmon; Snow Wreath, Future King, crimson; Lady Sophie Scott, rose; and Commodore Dewey, crimson; Seymour Lucas, an intensely crimson single variety was very good; Miss Edith Villiers, pink, and others.

Messrs. Webb & Sons, Wordsley, Stourbridge, had also a small group of unnamed single and double-flowered tuberous-rooted Begonias.

Messrs. F. Sander & Co., St. Albans, showed a few pretty little plants of ornamental-leaved Begonias, the varietal names being Conspicua, Gemmata, and Silver Bronze, all of them being very desirable plants.

CALADIUMS.

These handsome foliage plants always make one of the most prominent features in the shows at the Temple, and in the schedule Caladiums appeared amongst those that might be allowed the maximum amount of space, viz., 400 square feet. Though this seems very considerable in proportion to that permitted to Carnations and other popular plants, the large trade growers not only easily fill all the space they can obtain, but would gladly have more. There has never been a poor exhibit of Caladiums staged.

The best amateur's collection of Caladiums was one from Pantia Ralli, Esq., Ashstead Park, Epsom (gr., Mr. G. J. Hunt), which was rightly accorded a prominent position in tent No. 4. All of the plants in this exhibit were good, and they represented such first-rate varieties as Baron A. de Rothschild, Lord Derby, Orpheus, Sir Henry Irving, Silver Cloud (a novelty of three seasons ago), Silver Queen, Sir Julian Goldsmid, J. Pierpont Morgan (one of Messrs. Veitch's novelties in 1897), &c. One named Mr. Pantia Ralli was a handsome-leaved variety of the spotted type.

A little corner group of Caladiums from R. Hoffman, Esq., Thurlow Lodge, West Dulwich, was a very commendable amateur's exhibit, which, though less extensive than the magnificent trade displays, and though the plants were unnamed, included a quantity of moderate-sized plants of good varieties.

One of the best exhibits of Caladiums on this occasion was one from Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea. The plants, though not larger in size than have been staged previously at the Temple, were very perfect examples of good cultivation and high colouring. The disposition of the plants left nothing to be desired from the standpoint of effect; each plant could be seen to the best advantage, was absolutely clear of its neighbour, and displayed the habit of the plant, the form of leaf and colouring perfectly. The centre plant was a marvellously-good specimen of Rose Laing, a very pale-coloured leaf, with a rose-blush hue over the centre, and mottled with green towards the margins. At the back of the group were large specimens of Mrs. Harry Veitch, B. S. Williams, Gaspard Crayer, Baron Adolphe de Rothschild, Triomphe de Comte, Madame John Box, and Louis A. Van Houtte. Then there were candidum, Marquis of Camden, exceptionally coloured; Madame E. Pynaert, a self-coloured leaf of handsome appearance; Pantia Ralli, a large bronzy-green leaf, with whitish spots; and Oriflamme, very bright centre of leaf, with bronzy-green margins. Lady Mosely and Sir Stafford Northcote are two fine varieties, and recent novelties of Messrs. Veitch. The beautiful Ibis Rouge was represented by a plant of moderate size. Sir Edwin Smith is a large oval, flat leaf, with high-coloured nerves, a bronzy-green surface, and a few rather large, very irregular white spots. A particularly well-coloured plant of Madame Schmidt was noticed. The Mikado is, perhaps, the darkest coloured variety of Caladium obtainable, and very sombre in appearance. May Archer, a yellowish-white leaf with red margins to the ribs, and Mrs. C. Archer, a very bright self-coloured variety, are the newest in Messrs. Veitch's.

Messrs. John Laing & Sons, Stanstead Park Nurseries, Forest Hill, London, S.E., had a beautiful exhibit of Caladiums, most of them being of very superior merit, and though staged next to Messrs. Veitch & Sons' group of flowering plants, they suffered less in comparison than might have been expected. There were very fine plants of Gaspard Crayer, Triomphe de Comte, excellent, candidum, Baron A. de Rothschild, Baron de Mamore, Madame J. Box, Duchesse de Montemart, a pale yellow or white-leaved variety; Louis A. Van Houtte, a well-known, deeply self-coloured variety; and a very charming plant of Rose Laing.

Of novelties we noticed Illustration with leaves having a white or green ground, spotted, and occasionally suffused with red; Alexander III., a deep, but bright ruby-red-leaved variety of decided merit and good habit; Itapocii, a variety with green-and-red leaves, margined with pure green. There were pretty plants of Silver Cloud, Gaston Chandon, Golden Queen, and Ladas, among the smaller-sized plants.

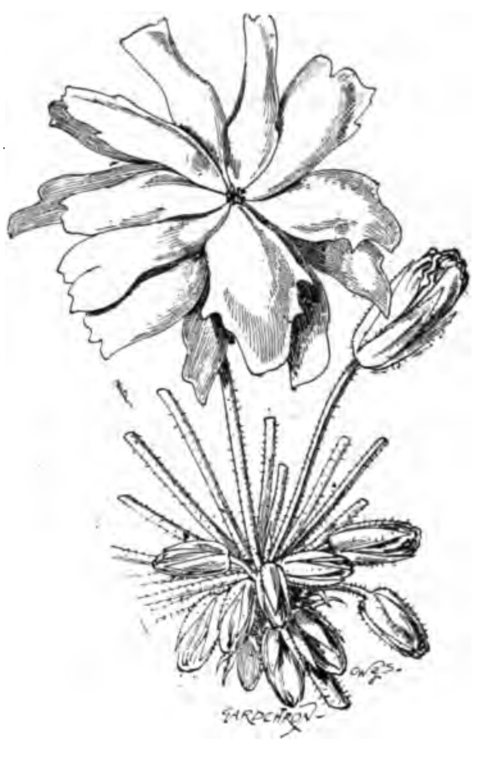

Fig. 128.—"Fire Dragon" Cactus Pelargonium: colour brilliant scarlet.

(As exhibited at the Temple Show by Mr. Ed. S. Powell.)

Messrs. J. Peed & Sons, Roupell Park Nurseries, West Norwood, Surrey, who have staged Caladiums wonderfully well at the Temple Show for some years past, made a grand exhibit. Not only were Messrs. Peed's Caladiums of very large size, some of them being shown in 12-inch to 14-inch pots, but they were grown in the same pots during the whole season. Some of the largest specimens represented varieties such as Madame J. Box, Sir William Broadbent, Mrs. Harry Veitch, candidum, the best specimen of Silver Cloud that we have seen, John Peed, Rose Laing, Roncador, Oriflamme, &c. There were smaller examples of Marie Mitjana, a self-coloured variety exceptionally well shown; Argentine, pale green and white; Mrs. John Peed, President M. de la Devansaye, W. E. Gladstone (new), a bronzy-green leaf with very deeply coloured ribs; Ibis Rose, Ibis Rouge, H. J. Chapman (new), a delicate looking variety of much merit, and many others.

DECORATIVE PLANTS IN POTS, &c.

CALCEOLARIAS.

Being the season of the Calceolaria, it was to be expected that several collections would put in an appearance.

At one end of the central Orchid stage in the large tent, Messrs. Sutton & Sons, of Reading, had a grand group of their fine strain, remarkable alike for dwarf, compact growth, brilliancy of tint, floriferousness and variety. Some finely-marbled, white-ground varieties were among them; and there were yellow and crimson selfs. The leading feature about present-day Calceolarias is the appearance of new combinations of colours. Some five dozen or so plants formed this attractive group.

Messrs. Webb & Sons, Wordsley, Stourbridge, had a table collection of fifty good specimens or so, a very good strain; but the growth of some of the plants a little taller than in the preceding group; though apparently not showing quite so much variation.

Messrs. James Carter & Co., seedsmen, High Holborn, had a table group of some hundred plants of high quality and variety, well grown and bloomed; in addition, they had a ground group of a good yellow self, which it is said comes true from seed from carefully-fertilised flowers. Here and there a few plants of Calceolarias appeared in miscellaneous collections of plants.

CARNATIONS

were to the fore in good quantity, the Malmaison type being in the ascendant. It appears possible that the increase in size in the ordinary Carnations will bring the types so closely together, that one type will be absorbed by the other.

In the Orchid-tent Mr. C. Blick, gr. to M. R. Smith, Esq., The Warren, Hayes, Kent, had a semi-circular group, prominent in which were several new Malmaisons, viz., Horace Hutchinson, which would certainly have received an Award of Merit, only that wire supports were used to keep the flowers in position, which is contrary to regulations; this is a bright crimson self, of excellent form. In addition there were Juliette, clear soft rose; King Oscar, pale red, intermediate in tint between the two preceding; Cecilia, a very fine large yellow; Baldwin, a large soft pink self, very pleasing; Mrs. Trelawny, pale scarlet; Calypso, delicate blush; Nautilus, a little deeper in tint; Mrs. Martin Smith, deeper still in tint; and others.

Messrs. F. Sander & Co. had three new varieties of Malmaison Carnations, viz., J. Coles, bright crimson, the flowers large but somewhat loose; Ivanhoe, not quite so dark, more of rose and less of crimson; and Lily Measures, pale rose or deep rosy pink.

Messrs. W. Cutbush & Son, nurserymen, Highgate, had a large group on the floor, mainly composed of a bed of Malmaison Carnation Princess of Wales, with two large and two smaller mounds of Carnations at certain points. Of new varieties, there were Henry James, deep reddish-rose, fine in petal; Herbert J. Cutbush, bright crimson, fine in petal; and Lady Ulrica, pale rose. Of older varieties, there were Calypso, Queen of Buffs, La Violette, deep pink on a cream ground; Sundridge, pale bright scarlet, fine petal; Germania, &c.

Mr. C. Turner, Royal Nursery, Slough, had a group comprising Sir Bevys, deep crimson self; Agamemnon, maroon; Miss Sophy Graham, soft salmon-pink; Rizzio, yellow, &c.

From Mr. Sanders, gr. to A. de Rothschild, Esq., Halton, Bucks, came two new Malmaison varieties, viz., Alfred de Rothschild, bright red; and Halstead, pale red, both of probable good character, but not presented in good character.

AZALEAS AND RHODODENDRONS.

Messrs. Cuthbert (R. & G.), Southgate, staged a most effective group of pontica and mollis varieties, which, by reason of its position, was seen to the best possible advantage. The plants were profusely flowered, the sulphur, creamy-whites, and the shades of salmon and orange, were specially attractive. The most striking were Charles Rivers, Phidias, Hugo Koster, Emily Liebig, Anthony Koster (fine), Rudyard Kipling, Aida, and Comte de Quincy.

Mr. John Russell, Richmond, also staged an excellent exhibit; the plants were not, however, quite so compact in growth as the former, but the shades of colour and variety were equally as good. The best were Norma and General Brailmont.

Mr. Chas. Turner staged a small group of the indica variety, which contained a few good plants; but, on the whole, they were but shades of the specimens of twenty years back.

Messrs. John Waterer & Sons staged a fine lot of well-flowered, medium-sized plants, many of which bore fine trusses; the best were Duchess of Connaught, Cynthia, Pink Pearl (extra fine), Marchioness of Lansdowne, and Sappho.

DRACÆNAS, ALOCASIAS, ETC.

Messrs. F. Sander & Co. showed a fine specimen of Dracæna Sanderiana, in first-rate character; D. Godseffiana was also in evidence in the same collection.

Mr. Wm. Bull, Chelsea, had a small group of Dracæna Victoria, a very fine form of D. Lindeni, the variegation being better defined, small plants being in excellent character. Other well-grown Dracænas were to be seen in the mixed groups of plants.

Messrs. Sander & Co. staged Alocasia spectabilis, like A. Lowii, but of better habit; also A. spectabilis nana.

ANTHURIUMS.

Messrs. F. Sander & Co. showed a small group, consisting chiefly of the Rothschildianum vars. of A. Scherzerianum, varying in the intensity of the crimson spots and blotches, all bearing fine spathes. Also A. Sanderæ, a form of A. Andreanum; a specially fine form of A. Scherzerianum was also shown, with an enormous spathe nearly 9 inches in length.

HARDY HERBACEOUS PLANTS, &c.

These were as usual very largely represented, and in great variety, commencing at the western end of the long tent on the north side.

Messrs. Wallace & Co., nurserymen, Colchester, had a group of Lilies in pots on the ground, and also cut flowers on a table. Among the former were L. × Marhan, Martagon × Hansoni, a distinct, dark-flowered form; × Dalhanson dalmaticum × Hansoni; Hansoni, in fine character; excelsum, very fine; giganteum, varieties of umbellatum and Thunbergianum, &c.; also hardy Cypripediums, such as spectabile, pubescens, very fine, acaule and montanum. Some very fine imported Pæonies from Japan, Calochorti, Brodiæas, Sparaxis: a variety named Fire King was very fine. Ixias, Iris of sorts, &c., a very interesting collection.

Messrs. T. S. Ware & Co. (Ltd.), Hall Farm Nurseries, Tottenham, had a collection of plants in pots and also cut specimens, including Lilium Harrisii, Spiræas, the double scarlet Geum, Cytisus scoparius Andreanus, Pæonies, hardy Cypripediums, Pyrethrums, Primula japonica, hardy Azaleas, Ononis rotundifolia, Anemone alpina sulphurea, Iris, Trollius, &c.

Messrs. G. Jackman & Son, nurserymen, Woking, who had an interesting collection, including Iris, Tritonia, Pæonies, Pyrethrums, Uvularia grandiflora, Incarvillea Delavayi, Lilacs, Aquilegias, Chrysogonum virginianum, Ononis rotundifolia, Campanula glomerata alba, Anemone sylvestris flore-pleno, Papaver nudicaule in variety, &c.

A very good collection was also staged by Messrs. Paul & Son, Old Nurseries, Cheshunt, which included some of the leading varieties of new Lilacs, viz., Madame Lemoine, Alphonse Lavallée, President Grévy, alba grandiflora, Madame Kreuter, Souvenir de Ludovic Späth, a grand dark variety, and President Carnot. Pæonies, Iris, Pyrethrums, pretty Alpines in baskets, Aquilegias, Tulips, Rhododendrons, Corydalis nobilis, &c.

Some fine flowering heads of Myosotidium nobile were staged by Mr. J. Stow, gr. to R. H. Fremlin, Esq., Wateringbury, Maidstone, which were greatly admired, and were the only examples in the show.

Mr. Jannoch, Dersingham, near Sandringham, had bunches of his fine strain of Lily of the Valley, and in another part of the show, Mr. W. Poupart, Marsh Farm, Twickenham, had superb examples of a very fine giant variety.

Messrs. Barr & Son had about twenty feet run of tabling arranged as an Alpine bank, on which had been planted a number of interesting subjects, but there was a great want of proper naming, to the disappointment of many. In addition there was a large bank, mainly of cut flowers, including various Poppies, Narcissus, Pyrethrums, Anemone palmata alba, A. sylvestris, and its double form; Trollius japonicus florepleno, Sweet Peas, Pæonies, Ixias, Sparaxis, early flowering Gladiolus, Iris of various types, &c. Probably the choicest collection of hardy plants came from Mr. M. Pritchard, Nurseryman Christchurch, who had plants and cut blooms both prominent being Cytisus purpureus incarnatus; Gypsophila cerastioides, a dwarf, white flowered plant, Asperula hirta, Gentiana verna, Linaria hepaticæfolia, Trollius Orange Globe, very fine; Phlox setacea, Vivid, Erica vulgaris aurea, Achillea mongolica, Spiræa Aruncus, var. Kneiffa, Hemerocallis Middendorfi, Dianthus alpinus, Pyrethrums, Erigeron aurantiacus, Lathyrus Sibthorpi, a very fine Everlasting Pea, Ourisia coccinea, &c.

Mr. Amos Perry, Nurseryman, Winchmore Hill, also staged an interesting collection, which included Phlox Canadensis, Tulips, Cytisus scoparius Andreanus, Delphinium nudicaule, Primula luteola, Arenaria grandiflora, Aquilegia Stuarti, A. cœrulea, &c. Trollius Fortunei, fl. pl., Globularia vulgaris, Ramondia pyrenaica, &c.

Mr. W. J. Godfrey, Nurseryman, Exmouth, had a collection of new forms of Papaver orientale, of the Blush Queen type, a few of them of decided promise, but they had suffered on the long journey, the best are Devonshire Lass, bronzy salmon; A. W. Chillery, a pleasing pink, and Admiration, a kind of rose-tinted crushed Strawberry tint.

The Guildford Hardy Plant Company had a very attractive arrangement in the form of an Alpine Garden, backed harmoniously by various dwarf shrubs. None of the subjects were named, but simply under number, which appeared to perplex visitors, who were desirous of identifying certain subjects.

Messrs. James Veitch & Sons had a group of Primula japonica in variety; and one of hybrid Aquilegias, edged with Hydrangea Mariesii.

PANSIES AND VIOLAS.

Messrs. Isaac House & Son, Westbury-on-Trym, Bristol, who are specialists in Pansies, had a collection of bunches of fancy varieties, prominent among them H. A. Stewart, James Cambell, D. S. McLennan, Mary Kay, Col. Buchannan, W. H. Clark, D. G. McKay, John Miller, James Maxwell, Mrs. J. Smellie; also baskets of fine fancy varieties, and also of Violas.

Mr. W. Sydenham, Tamworth, set up four dozen sprays of pretty Violas; the leading varieties, Mrs. R. N. Mitchell, Sir Visto, Blanche, Ethelward, Kingcup, Charm, The Mearns, Lizzie Paul, Sydney, Symphony, Queenie, Pembroke, W. Haig, Acme, Devonshire Cream, &c.; also six dozen of fine fancy Pansies on boards.

Messrs. J. Cheal & Sons, Nurserymen, Crawley, also had a collection of Violas set up in sprays on boards, arranged in panels and in groups, with Ferns and Moss, and with them were a few hardy flowers of various kinds.

Messrs. R. H. Bath & Co. (Ltd.), Wisbech, also had a number of fine blooms of Fancy Pansies, and a somewhat unusual sight in May, Cactus-Dahlias; and in addition, also Carnations Duke of York, Henry Gibb, and others, together with Iris, &c.

PÆONIES.

While blooms of these appeared in several collections of hardy flowers, the largest and most comprehensive group was staged by Messrs. Kelway & Sons, nurserymen, Langport. Among the newer varieties were Cecil Rhodes, rich rosy salmon; Ella C. Stubbs, a large white; Julius Cæsar, shaded crimson; Alchemist, deep crimson purple; Critis, salmon-pink; Diamond Jubilee, maroon, margined with white, with white stripes on the petal edges; William Robinson, white, with rosy-purple shading round the centre; Perosi, pale pinkish rose; Duchess of Marlborough, blush, with deeper centre; Mrs. William Kelway, large white; Lady Skelmersdale, delicate blush; Lord Kitchener, shining maroon; Lord Dunraven, pinkish rose; Henry Irving, maroon; Orme, maroon crimson; a fine bank of bunches of the same, and in addition such subjects as Eremurus himalaicus, Aquilegia cœrulea, Hippeastrums, &c.

Captain Forrens, Baston Manor, Hayes, had three fine varieties of Pæonies, imported from Japan; viz., a large white, a rosy salmon, and a maroon-purple.

TULIPS.

Messrs. Barr & Sons were the only exhibitors of these in anything like a representative collection. The lateness of the season was seen in the collection of late florists' Tulips they staged, which included flowered-bizarre Dr. Hardy, flowered-byblœmen Adonis and Talisman; flowered Roses, Kate Connor, Heroine and Mabel, and several breeders, such as Goldfinder, Talisman, Mabel, &c.; and of the so-called Darwin breeders, Fairy Queen, Hecla, The Sultan, Loveliness, &c.

FERNS.

In an imposing group many large specimens were shown by Messrs. Hill & Son, Lower Edmonton, London, and elevated on tall pedestals, and the utmost use was made of the limited space allowed. The whole group was well arranged, and all the plants were remarkably fresh and healthy. Of the larger specimens were Nephrolepis nigrescens tripinnatifida, Cibotium Scheidei, Asplenium caudatum (a very fine Fern for an elevated position); Davallia Mooreana, and a fine mass of Platycerium alcicorne; of Adiantum the tinted varieties were well represented, macrophyllum and its variety bipinnatum being very good; tinctum, cyclosorum, and others. Of those which do not show the bright tints, A. capillus-veneris imbricatum, Mariesii, Williamsii, mundulum, and many others were well shown. Davallias: of these the distinct and rare D. aculeata was represented by a fine specimen, tenuifolia Veitchi; immersa, solida, and alpina were also prominent. Aspleniums: of these marginatum, Hilli (a new variety of the bulbiferum type), nidus, esculentum, and, ornatum were prominent. Polypodiums included Schneideri, Irioides lingua, lingua heteractis, and a very fine plant of albo-punctatissimum. Platyceriums Willincki and æthiopicum, were prominent; of Pteris a fine basket of tricolor was shown, as well as Victoriæ, rubricaulis, and many others. Others worthy of note were Litobrochia vespertilionis, Aglaiomorpha Meyeriana, Goniophlebium subauriculatum, Gymnogrammas of sorts, Anemia rotundifolia, Lastreas, including the brightly-coloured erythrosora, Lygodiums, and many others, the whole forming a most interesting and attractive group.

In Mr. H. B. May's group from Dyson's Road Nursery, Upper Edmonton, pedestals were also used to some extent, but the great feature of the group was that many of the Ferns are grown on branching tree stems, which stand from 3 to 5 ft. high, and several plants being used for each stem, the effect was very pleasing. Davallias, Nephrolepis, Adiantums (the vars. with spreading rhizomes), and others, being treated in this way, while many of the smaller-growing Polypodiums, &c., were grown on short pieces of Tree-Fern trunks, covered with sphagnum-moss. In this group the Gymnogrammas were well represented, the most conspicuous being G. chrysophylla grandiceps superba, Alstoniæ flavescens and elegantissima are also good. Gleichenias include the best varieties, dicarpa longipinnata and rupestris glaucescens being very attractive. Some fine varieties of Asplenium were also shown, these include l Mayi, elegantissimum, and other varieties from the Baptisti section. Adiantums were well represented, and include Farleyense, also its variety alcicorne fovearum (brightly tinted with rosy-red), Bessonianum (a new variety of great merit), macrophyllum (highly coloured), fasciculatum dolabriforme (a pretty basket Fern), and many other useful varieties. Davallias: in addition to those shown on Tree-stems, many others were shown in pots and baskets, the varieties of Fijiensis being particularly interesting. Lygodiums were represented by scandens, japonica and polymorpha, all grown on tall, thin sticks. Platyceriums included grande Willincki, æthiopicum, and Hilli. In Polypodiums the beautiful P. Mayi, which was so much admired last year, was well shown. Another fine new Fern shown was Pteris Summersi, which originated from P. Wimsetti. Other fine garden varieties were included in this fine group.

Mr. Birkenhead's group from Sale, Manchester, though not so imposing as the others, was particularly interesting, as it included many species not often exhibited, and the plants, though small as a whole, were remarkably fresh and healthy. The filmy Ferns were well represented, and prettily arranged in a neat glass case. They included Trichomanes radicans, T. parvula, T. Colensoi, T. Alabamensis, Hymenophyllum Fosterianum, H. ciliatum, H. radicans dilatatum, and H. nitens. The hardy species and varieties included some choice forms of Athyriums, Polypodiums, Polystichums. Of the latter there are some fine forms of the plumosum section, the names of these, also those of the lady-Fern, being much too long to enumerate here. P. angulare divisilobium plumosissimum is shown in the Supplement; a fine plant of the North American-maiden-hair (Adiantum pedatum); also Osmunda Claytonianum, Asplenium trichomanes incisum, Blechnum trinervo coronans.

Of the more tender species, some very fine varieties of Gymnogramma schizophylla were shown, superba and gloriosa prolifera (see fig. in Supplement) being very pretty; the latter has a bulbil or young plant on each of the side pinnæ, these being covered with silvery-white farina. The Adiantums included the pretty little monochlamys, A. Lawsonianum, palmatum Luddemannianum, and others. Lomarias included some pretty small growing varieties. Note may be made of Banksi, pumila, crenulata, and the beautifully-coloured L'Herminieri. Lygodium microphyllum, L. volubile and dichotomum, Pteris moluccana and scaberula were well represented. Davallias included aculeata and the choice little D. pedata. Doodia amœna has bright red-tinted fronds. Anemia rotundifolia, A. villosa, Balantium culcita, Platyloma flexuosus, P. ternifolia, and a host of other interesting varieties were shown. We must not omit the beautiful violet-scented Fern, Asplenium fragrans, which, though one of the most difficult to manage, was well shown.

Fruit and Vegetable Committee.

Present: Philip Crowley, Esq. (Chairman), and Messrs. Richard Parker, W. Farr, J. W. Bates, Geo. Woodward, Wm. Pope, Jas. H. Veitch, H. Balderson, S. Mortimer, Geo. Bunyard, John Bashan, Robt. Fife, Chas. Herrin, F. Q. Lane, G. Reynolds, J. Willard, J. McIndoe, Geo. Wythes M. Gleeson, W. J. Empson, J. Wright, and Alex. Dean.

FRUIT TREES IN POTS.

The chief exhibit in this section was the very fine collection sent by Messrs. T. Rivers & Sons, Sawbridgeworth. It comprised twenty-four standard, pyramid, and bush trees in 11-inch pots, and several flat-trained trees, all in the best possible condition, and in fruit. There were also, as a central object, very fine fruits of Early Rivers' Nectarine, and Early York Peaches in boxes. The trees included of Peaches, Dr. Hogg, Crimson Galande, Stirling Castle, carrying twenty fine fruits, Hales' Early, Royal George, and Dagmar, rich crimson colour, one of the very best. Of Nectarines, Dryden of superb colour, Stanwick Elruge, also intensely coloured; Humboldt, Rivers' Orange, Cardinal, and Rivers' Early. There were of Plums, Early Prolific, and of Cherries the white Belle d'Orleans, and black Early Rivers. This fine collection had a place of honour in the large tent.

Messrs. G. Bunyard & Co., Maidstone, had elsewhere some eighteen trees and bushes, &c., in pots as a background to a fine collection of seventy dishes of Apples. Of trees, there were in good fruit, Alexander, Waterloo, and Hale's Early Peaches, Early Rivers' Nectarine, Denniston's Superb and red Magnum Bonum Plums, Madeline and St. John Figs, and several cordon Gooseberries. The Apples included, in capital condition, excellent samples of Calville Rouge, Calville Malingre, Calville Blanche, Alfriston, Smart's Prince Albert, Tibbett's Pearmain, Murfitt's Seedling, Striped Beefing, Lord Derby, Annie Elizabeth, Wellington, Newton Wonder, Norfolk Beefing, Gloria Mundi, and Bismarck; also Pears, Catillac and Uvedale's St. Germain, and a dish of good Alexander Peaches.

GENERAL COLLECTIONS OF FRUIT.

Of these a very fine one came from Sir Joseph Pease, M.P., whose gardener Mr. McIndoe, invariably brings from Hutton Hall, Guisborough, first class things. The background consisted of bunches of Black Hamburgh, Foster's Seedling, and early summer Frontignan Grapes, in trebles, admirably finished; and of dished fruits Melons, Scarlet Premier, and three seedlings. Also superb Black Tartarian, and White Bigarreau Napoleon, and Downton Cherries, a dozen fine Grosse Mignonne Peaches, early Rivers' Nectarines, Brown Turkey Figs, Catillac Pears, and McIndoe's Russet and Carlime Apples, with Oranges and Lemons, and Favourite Tomatos.

A by no means less valuable collection was that set up by Mr. Fyfe, gr. to Lord Wantage, Lockinge Park, Berks. This comprised twenty-two dishes, the whole being prettily dressed with Ixia flowers and grassy foliage set up in small glasses. At the back were very fine Madresfield Court and Foster's Seedling Grapes, and also Black Hamburgh and Buckland Sweetwater. Of Melons, Hero of Lockinge, of course, was fine, so also were some seedlings and huge Citrons. Beautiful samples of Stirling Castle Peaches, Impératrice Nectarines, superb in colour; Brown Turkey and white Ischia Figs, Royal Sovereign Strawberry, noble spikes of Monstera deliciosa, Tomatos, and some good Apples, of which Jack, and Fearn's Pippin, were richly coloured.

Mr. Ryder, gr. to the Countess of Limerick, St. Albans had a mixed collection of Fruit and Vegetables, inclusive of Grosse Mignonne Peaches, several dishes; also Strawberry Royal Sovereign, various Melons, Tomatos, Broccolis, Dwarf Beans, Peas, Cucumbers, Lettuces, Turnips, Potatos, &c., neatly set off with some small Palms.

Three dishes of Royal George Peaches were sent by Mr. B. Ashton, gr. to the Earl of Lathom, Lathom House, Ormskirk.

From Mr. W. Bastin, gr. to H. Henderson, Esq., Buscot Park, Berks, came a mixed collection. The fruit included excellent Hero of Lockinge, Earl's Favourite, Blenheim Orange, Royal Jubilee, and a seedling Melon, small Grapes, Figs, Tomatos, with piles of beautiful white, if small, First Crop Cauliflowers. Also Peas, Marrows, Cucumbers, French Beans, Carrots, really pleasingly displayed, the fruits especially being prominent in raised wicker stands.

Mr. W. Robins, gr. to Col. Lee, Hartwell House, Aylesbury, had fine Hales' Early Peaches, and four good Melons.

POT STRAWBERRIES

were shown by Mr. W. Allan, gr. to Lord Suffield, Gunton Park, Suffolk, who had excellently fruited plants of the new Lady Suffield, the fruits are deep coloured, long and tapering, and of capital flavour. After keen voting the Fruit Committee refused it an award because some of the fruits had not swelled up satisfactorily.

Messrs. Laxton & Sons, Bedford, set up very neatly n Ferns, some forty-two pots of their new variety Fillbasket, fruit well set on the plants, and somewhat pale in colour; and some pots of their fine variety Leader, with fruit larger and of deeper colour.

Mr. J. Crook, Forde Abbey Gardens, Chard, showed some vegetables, well kept Apple Sturmer Pippin, Dwarf Bean Progress, very freely podded, and Tomatos.

A very fine and representative collection of vegetables, with some fruit, was staged by Mr. W. J. Empson, gr. to the Hon. Mrs. Wingfield, Ampthill, Beds. A telling central figure was a huge bunch of Bananas, and there were numerous Melons, Sutton's Scarlet Golden Perfection, Hero of Lockinge, seedling, &c.; also the Strawberries, Leader, Royal Sovereign, and Sir J. Paxton. Tomatos, Dedham Favourite, Duke of York, and Market Favourite; of Peas in dishes, Carter's Daisy, Early Morn, and Springtide; and of Beans, Seville Mammoth Long Pod, Ne Plus Ultra, and Osborne's Forcing Dwarf. The background comprised Broccolis, Oxheart Cabbages, Lettuces, Cauliflowers, Giant Leeks, Radishes, &c., and also Cucumbers, Royal Osborne, and various other products, all of high quality, and set up in Mr. Empson's admirable style, making a most attractive exhibit.

Messrs. Webb & Sons, Wordsley, Stourbridge, had fine Cucumbers, Webb's Perpetual Bearer, and Improved Telegraph, also baskets of a fine Pea unnamed, and of Little Marvel Pea, and Harbinger Dwarf Beans.

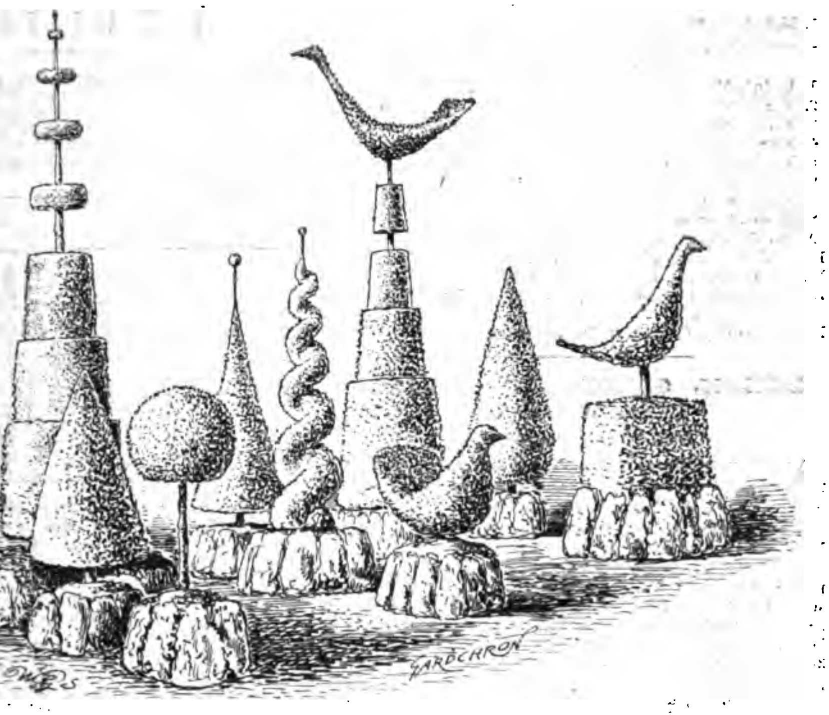

Fig. 129.—Topiary work at the Temple Show.

(Shown by J. Cheal & Sons. See Miscellaneous Exhibits.)

VEGETABLES.

These were frequently shown mixed with fruits, an arrangement convenient to the exhibitor but awkward for the reporter. For that reason it is needful to take the collections as we found them. A very fine exhibit was that put up by Mr. S. Mortimer, Rowledge, Farnham, who had seven boxes of Tomatos and five boxes of Cucumbers, in addition to various dishes, &c. The Tomatos comprised the new Winter Beauty, Perfection, Mitchell's Hybrid, Red Dessert, Sutton's A1, Challenger, Chemin Rouge, and The Cropper. Cucumbers were Improved Telegraph, Express, The Keeper, very deep colour; Prizewinner, Success, and a seedling, six fruits of each, and all of first-class quality. Also Melons Conqueror, Hero of Lockinge, Royal Sovereign, seedling Beau Ideal, and others, some twenty fruits.

Superb Asparagus came from Colchester, being shown by Mr. F. Chapman, who had seven bundles, perfect examples of this vegetable, Mr. W. Godfrey, who had six bundles, and also a bundle of fine Rhubarb, unnamed; and from Mr. A. J. Harwood, who had three bundles.

Messrs. A. W. Young & Co., Stevenage, had a nice lot of their Tomatos, Young's Eclipse, something after the style of Conference.

A most interesting collection of Mushrooms and spawn-cakes, illustrative of his methods of culture and spawn, came from Mr. R. E. Addey, Ealing Road, Brentford, the Mushrooms being presented in baskets in various stages of growth, and were in appearance exceedingly toothsome.

From the Swanley Horticultural College came a large collection of Vegetables, the best things of which were a standard-trained Cucumber, Peerless, carrying six good fruits, also very well fruited Tomatos in pots, and admirably done Dwarf Peas in pots, very fresh. Cucumbers were in great plenty, including Rochford's Magnum Bonum, Matchless, Every Day, &c. There was also a large collection of general vegetables, good and indifferent.

Messrs. Sutton & Sons, of Reading, put up a most interesting collection of superb Peas in baskets, samples equal to the finest out-door products, but having the bloom so finely preserved. The central figure of the collection was a big mound of the new Winter Tomato, Winter Beauty, the stock of which has become the property of the firm. The Peas were shown in broad and narrow round flats, and some in oblong ones; grand were the samples of Early Giant, also Excelsior, May Queen, Bountiful, and Duke of Albany. There were four of these baskets, and if the group was not a great one, the exhibits were of the highest excellence.

Messrs. Jas. Carter & Co., High Holborn, staged a fine and interesting exhibit, inclusive of in pots, Peas, Early Morn, Early Forcing, Anticipation, and Telephone. Also large baskets of Daisy, and the varieties just named, all capital samples.

There were also baskets of Climbing Bean, Case Knife, Duke of York Tomato, Blenheim Orange Melons, Long Sword, and White Advancer, Dwarf Beans, Beets, Radishes, Leeks, Earliest-of-All, and other Cucumbers, fine fruits; Lettuces, Cabbages, Carrots, &c., the whole presenting a collection of great excellence and value.

MISCELLANEOUS EXHIBITS.

Messrs. J. Carter & Co., High Holborn, staged some plants of Mimulus with very large, finely-marked flowers; the strain is known as "The Queen's Prize." Also very fine Giant Mignonette, Lilies-of-the-Valley from retarded crowns, and "Emperor" Petunias, single and double-flowered.

Messrs. Jas. Veitch & Sons, Chelsea, had a few plants of Primula japonica, some with pale-coloured flowers, others very rich purple. Also some pretty Aquilegias. Messrs. Veitch had also some plants of yellow-flowered Callas.

From R. I. Measures, Esq., Camberwell (gr., Mr. H. J. Chapman), came an exhibit of certain species of insectivorous plants. The only Nepenthes was a plant of N. Mastersii ×; but some very fine Sarracenias were staged, including S. Courti, Williamsii, Wrigleyana, and Chelsoni. There were also some fine Droseras, Cephalotus, &c.

Mr. Poupart, of Marsh Farm, Twickenham, showed some exceptionally strongly-grown Lilies-of-the-Valley, exhibited in sprays tied up in the shape of fans.

Mr. Jannoch, of Dersingham, Norfolk, had a very fine exhibit of Lilies-of-the-Valley from retarded crowns, displayed in the cone-shaped masses this well-known cultivator has become famous for.

Messrs. Sutton & Sons, Reading, made a very attractive exhibit of their strains of Nemesia strumosa, a free-flowering annual with very prettily-marked flowers. The older strain may be had in four distinct colours; but in the newer strain, which appears to bear rather smaller and even more numerous flowers, some with blue blooms were noticed—a colour not found in the earlier strain.

Messrs. John Laing & Sons, Forest Hill, S.E., exhibited a batch of plants of their "multiflora" strain of Streptocarpus, in which several novel tints were noticed.

Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, had also Rhododendrons, Azaleas, and a topiary exhibit of Box and Yew trees, a revival of an old-fashioned fancy which we cherish when old, but deprecate when new. (See fig. 129, p. 365.)

Messrs. Jno. Waterer & Sons, American Nurseries, Bagshot, showed a nice little collection of hardy Conifers, including several varieties of Cupressus Lawsoniana and of Retinospora; their Taxus japonica is the fastigiate form of Cephalotaxus pedunculata.

A fine group of hardy Bamboos was arranged out-of-doors by Messrs. James Veitch & Sons. There were Phyllostachys nigra × punctata aurea castellionis, Arundinaria Fortunei, nitida Hindsii, chrysantha, &c.; Bambusa Alphonse Kari palmata, angustifolia, tessellata, &c.

Bamboos were also well shown by Mr. V. N. Gauntlett, Redruth.

Awards of the Floral Committee.

Acer pseudo-platanus var. elegantissima variegata. A very ornamental, perfectly hardy Maple. The early foliage is reddish in colour, changing to cream, and finally to a clear variegation of pale yellow and green. A dozen strong plants were shown, each about 5 ft. high.—From Messrs. T. Perkins & Son, Northampton.

Anemone sylvestris flore pleno.—A full double form, with handsome white cone-like blossoms. From Messrs. G. Jackman & Son, Woking. (Award of Merit.)

Begonia Duke of Devonshire.—A flat-petalled, smooth flower, with high centre until the flower has developed. Colour intense crimson. From Mr. T. S. Ware & Co., Ltd. (Award of Merit.)

Begonia Miss Barbara Ray.—Very beautiful and distinct in colour, being a shade of orange-red. In form the flower much resembles a Rose, but has more "centres" than one. From T. S. Ware & Co., Ltd. (Award of Merit.)

Begonia Miss Bella Tait.—An exceptionally large globular-like flower of salmon-scarlet colour, with wavy outlines to the petals. From Mr. T. S. Ware & Co., Ltd. (Award of Merit.)

Begonia Miss Mary Pope (see fig. 127) is a pure white Camellia-shaped flower, the actual size of which may be seen from the illustration. It is one of the best Begonias ever exhibited, and as a pure white flower unexcelled. While the plant has a very good, free-flowering habit, the flower-stems are not proportionate in strength to the weight of the blooms. From T. S. Ware & Co., Ltd. (Award of Merit.)

Dracæna cannæfolia variegata.—An ornamental Dracæna with green and yellow foliage, the stem being as long or longer than the blade of the leaf, which is about 2½ inches in width. The plant has a distinct and handsome appearance. From Messrs. John Laing & Sons. (Award of Merit.)

Heliconia Sanderi is a most ornamental variety. Three large plants were exhibited by Messrs. F. Sander & Co., and as these were protected by a large glass case, it was not convenient to inspect them with a view to making a minute description. The leaves are large and handsome, some of them almost white over the whole surface, and in others the variegation is generally in lines. (First-class Certificate).

Ilex Wilsoni.—Messrs. Fisher, Son, & Sibray. (First-class Certificate.) (See p. 362.)

Juniperus Sanderi.—Probably a temporary form of Juniperus sinensis. It has blue-green needles in place of the green, and is very pretty. From Messrs. F. Sander & Co. (First-class Certificate.)

Pæonia arborea Cecil Rhodes.—A rich, rosy salmon-coloured flower, large, and very fine. From Messrs. Kelway & Son. (Award of Merit.)

Pæonia arborea Miss Beatrice Jones.—A charming white-flowered variety of fine form, the centre tinted with rosy-purple. From Messrs. Kelway & Sons. (Award of Merit.)

Phyllocactus Admiration.—A beautiful flower of warm flesh-colour to rich pink; of very pleasing form. From Messrs. J. Veitch & Sons. (Award of Merit.)

Phyllocactus J. T. Peacock Improved.—A larger flower than the type, being a seedling from J. T. Peacock after being crossed with Niobe. From Messrs. J. Veitch & Sons. (Award of Merit.)

Phyllocactus Nysa.—A very spreading flower of a rich, warm purple shade of cerise. From Messrs. J. Veitch & Sons. (Award of Merit.)

Polystichum angulare divisilobum plumosissimum. — A novelty showing a remarkable second growth upon the fronds made last year; very dense and beautiful. It is in the way of P. a. d. plumosum densum Esplei, but is vastly superior. (See fig. in supplement.) From Messrs. W. & J. Birkenhead. (First-class Certificate.)

Awards.

First-class Certificates.

To Odontoglossum crispum, Arthur Briscoe, shown by W. Thompson, Esq., Walton Grange, Stone.

Cattleya Mossiæ "Beauty of Bush Hill," Messrs. Hugh Low & Co., Bush Hill Park.

Lælio-Cattleya Aphrodite, var. Madame Albert Hye, M. Jules Hye, Ghent.

Lælio-Cattleya Aphrodite "Ruth," J. Rutherford, Esq., M.P., Beardwood, Blackburn.

Lælia purpurata "Annie Louise," G. W. Law-Schofield, Esq., Rawtenstall.

Awards of Merit.

To Odontoglossum triumphans "King Alfred," W. Thompson, Esq., Walton Grange, Stone.

Phalænopsis Sanderiana, Wigan's var., Sir F. Wigan, Clare Lawn, East Sheen.

Miltonia vexillaria Dulcotensis, Walter Cobb, Esq., Tunbridge Wells.

Cattleya Mossiæ Goossensiana; Cattleya Mendeli, Burford variety; and Thunia Bensoniæ superba, Sir Trevor Lawrence, Burford, Dorking.

Cattleya intermedia, Rosslyn var.; H. T. Pitt, Esq., Stamford Hill.

Cattleya Mendeli "Perfection;" Messrs. Hugh Low & Co., Bush Hill Park.

Cattleya Mossiæ "Mrs. C. H. Feiling;" Messrs. Stanley-Mobbs & Ashton, Southgate.

Odontoglossum Halli de Laissemanum; O. crispum "Perle du Congo;" Mons. Jules Hye, Ghent.

Odontoglossum var. "Miss Linden;" Miltonia vexillaria Lindeniæ; M. Linden, Brussels.

Cattleya Mossiæ gloriosa; J. Rutherford, Esq., M.P., Beardwood, Blackburn.

Botanical Certificate.

Campanemia uliginosa; and Cypripedium glanduliferum; Sir Trevor Lawrence.

Gold Medals.

1. Sir Trevor Lawrence, Bt., for Orchids.
2. M. Jules Hye, Ghent, for Orchids.
3. Messrs. J. Veitch & Sons, Chelsea, for Phyllocactus, Caladiums, Gloxinias, Shrubs in Flower, and Bamboos.
4. Messrs. Fisher, Son & Sibray, Handsworth, Sheffield, for Shrubs and Foliage-plants.
5. Messrs. T. S. Ware & Co., Tottenham, for Begonias.

Silver Cups.

1. M. L. Linden, Brussels, for Orchids.
2. Sir F. Wigan, Bart., for Orchids.
3. Messrs. F. Sander & Co., St. Albans, for Orchids and New and Rare Plants.
4. Messrs. Charlesworth & Co., Bradford, for Orchids.
5. Messrs. Hugh Low & Co., Enfield, for Orchids.
6. Messrs. Paul & Son, Cheshunt, for Roses, &c.
7. Mr. Geo. Mount, Canterbury, for Roses.
8. Messrs. W. Paul & Son, Waltham Cross, for Roses.
9. Mr. H. B. May, Edmonton, for Ferns.
10. R. I. Measures, Esq., Camberwell, for Insectivorous Plants.
11. Messrs. Wills & Segar, South Kensington, for Foliage-plants.
12. Messrs. Geo. Bunyard & Co., Maidstone, for Apple and Fruit-trees.
13. Lord Wantage, Lockinge, for Fruit.
14. Messrs. T. F. Rivers & Son, Sawbridgeworth, for Fruit.
15. Messrs. J. Laing & Sons, Forest Hill, for Streptocarpus, Caladiums, and Begonias.
16. Messrs. Sutton & Sons, Reading, for vegetables and Calceolarias.
17. Messrs. J. Backhouse & Son, York, for Miscellaneous Plants and Alpines.
18. W. Thompson, Esq., Stone, for Orchids.
19. J. Rutherford, Esq., M.P., Blackburn, for Orchids.
20. Mr. J. Cypher, Cheltenham, for Orchids.
21. Mr. C. Turner, Slough, for Roses, Azaleas, and Carnations.

Silver-gilt Flora Medals.

1. Messrs. Stanley-Mobbs & Ashton, Southgate, for Orchids.
2. Messrs. Cuthbert, Southgate, for Azaleas.
3. Martin Smith, Esq., Hayes, for Carnations.
4. Messrs. Jackman, Woking, for Clematis.
5. Messrs. R. Smith, Worcester, for Clematis.
6. The Guildford Hardy Plant Co., for Alpines.
7. Messrs. Kelway & Sons, Langport, for Pæonies.
8. Messrs. W. Cutbush & Son, Highgate, for Flowering Shrubs, &c.
9. Mr. J. Hill, Edmonton, for Ferns.
10. Messrs. Fromow & Sons, Chiswick, for Maples.
11. Messrs. Wallace & Co., Colchester, for Lilies, &c.
12. Messrs. J. Waterer & Sons, Bagshot, for Rhododendrons, &c.
13. Messrs. Cannell & Sons, Swanley, for Cannas, Gloxinias, and Begonias.
14. Pantia Ralli, Esq., Ashtead, for Caladiums.
15. Messrs. J. Peed & Sons, West Norwood, for Caladiums and Gloxinias.

Silver-gilt Knightian Medals.

1. A. Henderson, Esq., M.P., Faringdon, for Fruit.
2. Sir J. Pease, Bart., M.P., Guisborough, for Fruit.
3. Mrs. Wingfield, Ampthill House, Ampthill, for Fruit and Vegetables.
4. Mr. S. Mortimer, Farnham, for Fruit and Vegetables.

Silver-gilt Banksian Medals.

1. W. A. Gillett, Esq., Bishopstoke, for Orchids.
2. W. C. Walker, Esq., Winchmore Hill, for Orchid.
3. Messrs. B. S. Williams, Upper Holloway, for Orchid.
4. Mr. A. Perry, Winchmore Hill, for Herbaceous Plants.
5. Mr. W. Bull, Chelsea, for Dracænas.
6. Messrs. J. Birkenhead, Sale, for Ferns.
7. Mr. W. Iceton, Putney, for Palms.
8. Swanley College, Kent, for Vegetables.
9. Mr. J. Russell, Richmond, for Hardy Plants and Azaleas.
10. Messrs. J. Cheal & Sons, Crawley, Sussex, for Herbaceous Plants and Shrubs.
11. Messrs. Barr & Sons, Covent Garden, for Herbaceous Plants.
12. Messrs. Carter & Co., Holborn, for Calceolareas, Vegetables, &c.

Silver Flora Medals.

1. Malcolm S. Cooke, Esq., Kingston, for Orchids.
2. Messrs. Cripps & Son, Tonbridge Wells, for Maples.

Silver Banksian Medals.

1. Ludwig Mond, Esq., Regent's Park, for Orchids.
2. Messrs. Webb, Stourbridge, for Gloxinias and Calceolarias.
3. Mr. Pritchard, Christchurch, for Herbaceous Plants.
4. Messrs. House, Bristol, for Violas.
5. Mr. Jannoch, Dersingham, for Lilies of the Valley.
6. Messrs. Van Waveren, Haarlem, for Astilbes.
7. Mr. W. Poupart, Twickenham, for Lilies of the Valley.
8. Messrs. Storrie, Dundee, for Auriculas.
9. Mr. T. Perkins, Northampton, for Sycamores.
10. R. Hoffman, Esq., Dulwich, for Caladiums.
11. Mr. H. J. Jones, Lewisham, for Begonias.
12. The Countess of Limerick, St. Albans, for Fruit and Vegetables.
13. Mr. Godfrey, Colchester, for Asparagus.

BRISTOL GARDENERS' MUTUAL IMPROVEMENT.

TOMATO CULTIVATION.

A large number of members attended the first meeting of the summer session to hear a paper on "Tomato Culture" by Mr. C. Lock, the chairman of the Society.

In a paper bristling with useful hints on the subject, Mr. Lock dealt with the mode of culture for early, mid-season, and late crops. He stated that though a large number of people grew Tomato-plants, not more than 10 per cent. succeeded in obtaining the best results from them. He recommended that the seed be sown thinly in shallow pans or boxes, the seedlings to be potted as early as possible into 8-inch pots, and when strong enough to be again re-potted or planted in their fruiting quarters. The soil should be good loam and manure, and when the first fruits are set, a mulching may be given. Mr. Lock also gave practical advice upon the important subjects of ventilating, watering, and upon the diseases that attack Tomatos. The variety recommended above all others was Ham Green Favourite.

Prizes for brace of Cucumbers were awarded to Messrs. Marshall and Frampton; and the Society's Certificate of Merit was awarded to Mr. Shaddeck, for a fine specimen of Cypripedium barbatum.

THE BATH and WEST and SOUTHERN COUNTIES.

May 24, 29.—The horticultural exhibits in connection with the Exeter show of the above Society were varied and interesting, a large tent being devoted to this section.

Immediately on entering we noted a fine display from Messrs. W. Cutbush & Sons, Highgate and Barnet, London in which were many of the new varieties of double Azalea mollis, a nice lot of Taheita Oranges bearing quantities of fruit, Lilium Harrisianum, Calla Elliottiana, very choice, and some capital plants of Malmaison and other Carnations. Messrs. B. Brown & Sons, St. Thomas, Exeter, had a capital group of miscellaneous plants, full of flower, and some choice wreaths, bouquets, &c. Messrs. Paul & Sons, Cheshunt, Herts, occupied a large space, showing a number of spikes of Amaryllis with large and showy flowers; Pæonies in quantity, also single and double-flowering Lilacs. Some standard and dwarf Tea Roses were full of bloom, the new H.T. Dawn being very well shown. The new Macartney berberifolia Rose, hardy single yellow, and the Polyantha Rose, Psyche, were in close proximity to fine standard and bush plants of Turner's Crimson Rambler, which, in this stand and several others in the tent, were very freely flowered. Messrs. J. Laing & Sons, Forest Hill, London, had nice Codiæums, Streptocarpus, Begonias, and Ferns. Messrs. Barr & Sons, Covent Garden and Long Ditton, Surrey, showed Darwin Tulips and Tulipa species; also a capital collection of single Pæonies and other hardy flowers. Messrs. Kelway & Son, Langport, Somerset, had a large stand of tree Pæonies full of showy flowers. The end of the tent was occupied by the Messrs. R. Veitch & Sons, Exeter, who had a most artistic and effective display. Bamboos, Maples, Coniferæ, Cytisus, Rhododendrons were arranged at the back, and lower down the surface was broken by a waterfall and pond, in which M. Marliac's new Lilies were planted and bearing flowers. Crimson Rambler Roses were trained up the pillars; one of these being 12 feet high and full of bloom. The portion in the front was covered with choice herbaceous plants and greenhouse shrubs. Sarracenias, Callas, Magnolias, Hydrangea Mariesii, Carpenteria californica, Gerbera Jamesoni, the new Dimorphotheca Eckloni, and Calla Elliottiana were particularly good. Messrs. G. Cooling & Sons, Bath, showed Spanish Iris in quantity; also double Lilacs, Tea Roses in vases, and Fortin's large-flowered Lily of the Valley. Mr. W. J. Godfrey, Exmouth, had cut spikes of Lilacs and choice varieties of Cannas, seedling, show and zonal Pelargoniums, many new oriental Poppies, Carnations, Tropæolum Exmouth Yellow, &c. Mr. Hooper, of Bath, showed a collection of Pansies.

Among amateurs, B. H. Hill, Esq., Newcombes, Crediton (gr., Mr. G. Locke), had a splendid group of plants. Major Brock, Exeter (gr., Mr. Rowland), had a large exhibit, in which were many plants full of flower.

Walking in the grounds, in consequence of the soddened state of the pathways, &c., was a matter of considerable discomfort, but the horticultural tent was drier, and was frequently crowded with visitors.

THE WEATHER.

[The term "accumulated temperature indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

Districts.	Temperature.						Rainfall.			Bright Sun.	
	Above (+) or below (−) the Mean for the week ending May 27.	Accumulated.				More (+) or less (−) than Mean for the Week.	No. of Rainy Days since January 1, 1899.	Total Fall since Jan. 1, 1899.	Percentage of possible Duration for the Week.	Percentage of possible Duration since Jan. 1, 1899.
		Above 42° for the Week.	Below 42° for the Week.	Above 42°, difference from Mean since January 1, 1899.	Below 42°, difference from Mean since January 1, 1899.

The districts indicated by number in the first column are the following:—

0, Scotland, N. *Principal Wheat-producing Districts*—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. *Principal Grazing, &c., Districts*—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 27, is furnished from the Meteorological Office:—

"The *weather* was unsettled, rainy, and fairly mild in most parts of the kingdom during the earlier half of the week, but subsequently became cold, fine, dry, and harsh generally. Thunder and lightning were experienced in many places at about the middle of the period.

"The *temperature* was below the mean in all districts, the deficit ranging from 1° in 'England, S.W.,' and the 'Channel Islands,' to 5° in 'Scotland, W.,' and the 'Midland Counties,' 6° in 'Scotland, N,' and 'England, N.E.,' and to as much as 8° in 'Scotland, E.' The highest of the maxima were recorded on the 23rd over England and Ireland, and on the 27th in Scotland; they ranged from 66° in 'England, S.,' and 65° in 'Scotland, N. and E.,' and 'England, E.,' to 60° in the 'Channel Islands' and 'England, N.W.,' to 57° in 'England, N.E.' The lowest of the minima were registered on the 27th, and ranged from 27° in 'Scotland, E.,' 29° in 'Scotland, N.,' and 30° in the 'Midland Counties,' to 34° in 'Scotland, W.,' and 'England, E. and S.W.,' and to 45° in the 'Channel Islands.'

"The *rainfall* was less than the mean in Scotland as well as in 'England, S.,' but rather more than the normal in all other districts.

"The *bright sunshine* was again deficient over the kingdom as a whole, but exceeded the mean in 'Scotland, N.,' and just equalled it in 'Ireland, S.' The percentage of the possible duration ranged from 42 in 'Scotland, N.,' 41 in 'Ireland, S.,' and 39 in the 'Channel Islands,' to 22 in 'England, N.W.,' and 21 in 'Scotland, W.'"

MARKETS.

COVENT GARDEN, JUNE 1.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Potatos.

Bruce, Main Crop, Up-to-Date, &c., 60s. to 90s.; Dunbar Main Crop, 100s. to 110s. Jersey New, 12s. to 14s. per cwt; Canary, 13s. to 14s.; Cherbourg and St. Malo, 11s. to 12s.; Lisbon, per box, 4s. 6d. to 4s. 9d. *John Bath, 32 and 34, Wellington Street, Covent Garden.*

Remarks.—During the week Cabbage improved in price; Spinach declined, owing to larger supply; Radishes plentiful, and low in price; New Potatos have a downward tendency, and Gooseberries may be expected to be much less in price ere the week ends. English Peas have commenced in sieves or half-bushels. The Australian Grapes, called Daria (very like the Almeria), in cases marked 30 lb. nett, come in fair condition, packed, some in red-wood dust, some in cork-dust, the last decidedly the better.

SEEDS.

London: *May* 31.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that to day's seed market, as was to be expected, proved bare alike of buyers and of business. The season being over, Clover seed is now naturally a dead letter. Occasional small orders still drop in for spring Tares. As regards sowing Mustard and Rapeseed, the market is very strong. Blue Peas and Haricot Beans are also firm; whilst in Canary-seed, a greatly improved feeling is shown, and as the result of persistent bad crop reports, and consequent speculative buying thereon, a substantial advance in values has been established. Hempseed, moreover, continues scarce and dear, Linseed is steady. More money is asked for Scarlet Runners.

CORN.

Average Prices of British Corn (per imperial qr.), for the week ending May 27, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.		1899.		Difference.		
	s.	d.	s.	d.		s.	d.
Wheat	47	9	25	2	—	22	7
Barley	26	5	23	8	—	2	9
Oats	21	5	17	8	—	3	9

FRUIT AND VEGETABLES.

Glasgow: *May* 31.—The following are the averages of the prices recorded since our last report:—Apples, Canadian Spies, 14s. to 18s. per barrel; Western States' Russets, 18s. to 20s. do.; Oranges, 6*d*. to 1s. per dozen; Grapes, home, 2s. to 4s. 6*d*. per lb.; do., foreign, 6*d*. do.; Tomatos, Guernsey, 4*d*. to 8*d*. per lb.; do., Scotch, 5*d*. to 8*d*. do.; Cabbages, Spring, 6*d*. to 1s. per dozen; Leeks, 2s. to 2s. 6*d*. per dozen bunches; Mint, green, 6*d*. per bunch; Onions, 4s. 6*d*. to 5s. per cwt.; Parsley, 2s. to 2s. 6*d*. per stone; Carrots, new, 1s. per bunch, and 4s. 6*d*. to 8s. per cwt.; Cucumbers, 4*d*. to 5*d*. each; Lettuces, round, 1s. 3*d*. to 1s. 6*d*. per dozen; do., Cos, 4s. to 5s. do.; Radishes, long, English, 1s. 6*d*. per dozen bunches; round, do., 1s. 6*d*. to 2s. do.; Horseradish, 1s. 6*d*. to 2s. per bundle; Mushrooms, 1s. to 1s. 2*d*. per lb.; Beetroots, 6*d*. to 7*d*. per dozen; Mustard and Cress, 3*d*. per punnet; Spinach, 2s. to 4s. per stone; Rhubarb, 2s. 6*d*. to 3s. 6*d*. per cwt.; Turnips, French, white, 1s. to 1s. 3*d*. per bunch; Swedes, 2s. to 2s. 6*d*. per bag; Broccoli, Irish, 2s. to 2s. 6*d* per dozen; Greens, 5s. to 6s. per 10 dozen.

Liverpool: *May* 31. — *Wholesale Vegetable Market.* — Potatos, per cwt., Main Crop, 3s. 8*d*. to 4s.; Bruce, 2s. 9*d*. to 3s. 6*d*.; Champion, 2s. 6*d*. to 3s.; Turnips, Swedes, 2s. 6*d*. do.; Carrots, 5s. 6*d*. to 6s. do.; Parsley, 6*d*. to 8*d*. per dozen bunches; Onions, foreign, 4s. to 5s. per cwt.; Lettuces, 8*d*. to 1s. per dozen; Cucumbers, 1s. 3*d*. to 3s. per dozen; Cauliflowers, 1s. 3*d*. to 3s. do.; Cabbages, 10*d*. to 1s. 6*d*. do. *St. John's.*—Potatos, 1s. to 1s. 3*d*. per peck; do., new, 2*d*. to 3*d*. per lb.; Grapes, home, 2s. 6*d*. to 4s. do.; Pines, English, 4s. to 6s. each; Strawberries, 6*d*. to 1s. per lb.; Peas, 4*d*. to 1s. per lb.; Cherries, 6*d*. to 1s. do.; Cob Nuts, 6*d*. do.; Apricots, 1s. per dozen; Asparagus, 2s. 6*d*. to 4s. per 100; do., bundle, 1s. 6*d*. to 3s.; Cucumbers, 3*d*. to 4*d*. each; Mushrooms, 1s. 4*d*. per pound and basket. *Birkenhead.*—Potatos, 1s. to 1s. 2*d*. per peck; do. new, 1½*d*. to 3*d*. per lb. Peas, 3*d*. to 5*d*. do.; Asparagus, 1s. 9*d*. to 4s. per 100; Cucumbers, 3*d*. to 6*d*. each; Strawberries, 6*d*. to 1s. per lb.; Cherries, 6*d*. to 10*d*. do.; Apricots, 1s. per dozen; Gooseberries, 4*d*. to 6*d*. per lb.; Grapes, home, 2s. to 3s. 6*d*. do.; Mushrooms, 1s. to 1s. 6*d*. do.

SOUTH AFRICAN NOTES.

THE EFFECT OF FROST ON TROPICAL PLANTS.

The greatest cold registered here for several years was 21° below freezing-point, Fahr., on the night of July 10, 1898, under a screen 4 feet from the ground. The cold was severe enough to burst water-taps in the open, and long icicles formed under our fountain, remaining unmelted for several days. No rain fell or snow, the air being very dry. Many half-hardy plants were killed, but several tropical subjects survived.

Aristolochia ornithocephala on a trellis in the open was quite dead above ground, but to my surprise it sent up a strong shoot as the summer came on, and is now (March) flowering very well. A companion plant of A. elegans was also hard hit, and is now growing well, but has produced no flowers. Gerbera Jamesoni I gave up for lost, but it soon sent up fine leaves and flowers; this is one of the very best native flowering herbaceous plants that we have. Cobæa scandens was quite killed, as was Pittosporum undulatum. Mesembryanthemums just survived, as also Pelargoniums and Fuchsias, though F. corymbiflora under a wall was killed. Mackaya bella died, but Gardenia Thunbergi pulled through. Fourcroya Lindeni and Bromelia bracteata, it is strange to say, look none the worse after being frozen hard; Pancratium calathinum proved quite hardy; also Hedychium Gardnerianum, Caladium esculentum, Tweedica cœrulea, Thunbergia natalensis, Laurus Camphora, Acacia cultriformis, Melaleuca speciosa, and Solanum jasminoides. Araucaria Bidwilli, A. Cunninghami, and A. excelsa lost their tops; Musa Ensete survived with a thick grass thatching; Leonotis Leonurus, Wigandia urens, a fine hybrid Passiflora (much like P. quadrangularis), Lagerstrœmia indica, most hybrid Abutilons (except A. megapotamicum, which is quite hardy), Habrothamnus elegans, H. aurantiacus, Metrosideros decussata, and Bougainvilleas were all cut to the ground, but shot up again from the roots. Passiflora edulis, Bouvardias, Ricinus communis, hybrid Salvias, and Brugmansia suaveolens were nearly killed; Encephalartos caffra and E. villosus survived; Nymphæa cœrulea proved quite hardy.

Amongst trees, Grevillea robusta, Eucalyptus robusta, E. leucoxylon, and young E. Globulus lost their leaves, but soon revived. Eucalyptus citriodorus was killed to the ground, but it eventually sent up a strong shoot. Eucalyptus terminalis was quite untouched; Casuarina tenuissima was badly scorched; Acacia melanoxylon, A. mollissima, and A. dealbata, proved hardy. It was remarkable to see the last-named a mass of golden bloom at a time when the frost was most severe; even the half-expanded flowers were uninjured. Also flowering in mid-winter were Sutherlandia frutescens and Buddleia salvifolia.

Such plants as Tuberoses, hybrid Cannas, Sparaxis pendula, Richardias, and dwarf Bamboos, came through the ordeal all right. Bambusa arundinacea (Giant Indian Bamboo) was killed to the ground, but afterwards sent up fresh growth. Tree-Ferns and Palms, I have learnt from experience, never to plant in the open, as the wind and dust-storms soon render them miserable objects. Indian Azaleas, Camellias, and Rhododendrons, in tubs under a trellis, did not lose a leaf. Young Lemon-trees were cut to the ground. The only species amongst Cacti which will endure the winter frost is the Prickly Pear (Opuntia vulgaris). Of a large collection of Yuccas, none was injured. The Y. Wipplei does very well here. *R. W. Adlam, Joubert Park, Johannesburg.*

CATALOGUES RECEIVED.

Chantrier Frères, Mortefontaine, Plailly, Oise, France—Stove and Greenhouse Plants, Palms, Ferns, Orchids, &c.

John Peed & Son, Roupel Park Nursery, London, S.E.—Caladiums, Codiæums, Cordylines, &c.

GARDENING APPOINTMENTS.

Mr. W. R. Hinton, formerly Gardener at The Grove, Epsom, as Gardener to Nevile Reid, Esq., The Oaks, Hanworth, Middlesex.

Mr. W. E. Wynne, as Gardener to R. Francies, Esq., Crofton Hall, Orpington, Kent.

Mr. John Harriss, lately of Balchitha Gardens, Greenock, and at present in Messrs. Ker & Son's Aigburth Nursery, Liverpool, as Head Gardener to C. Taylor, Esq., Ash Grange, Whitchurch, Shropshire.

Mr. James Bell, for the past four years Foreman in the Gardens, Jesmond Towers, Newcastle-on-Tyne, as Head Gardener to A. Henderson, Esq., Leazes House, Durham.

Mr. Wm. Arthur, as Head Gardener to F. B. Atkinson, Cresswell Hall, Morpeth.

Mr. James Dent, late Gardener at Downton Castle, Herefordshire, as Head Gardener to the Hon. Mrs. Barton, Luttrellstown Castle, Clonsilla, Co. Dublin.

ENQUIRY.

Twice-named Plants.—An enquirer asks if there is any law forbidding the offer for sale, under a new name, of an established variety, or one previously introduced? We do not know of any special legislation, beyond the ordinary law for the repression of fraud and misrepresentation.

Answers to Correspondents

A Collection of Salad: *Mrs. S. C. H.* In the month of August, the collection might consist of Lettuces, Cos and Cabbage varieties; Radishes, long, medium, and Turnip-rooted; Cresses, various, including Normandy and Water-Cress; Egyptian Beetroot, young Onions, the earliest blanched Celery, Cucumbers, Tomatos, Gherkins, Tarragon, tender leaves of Sorrel, bulbs of Garlic, and Shallots. From these nine kinds could be selected according to fancy.

Apple Shoots: *Correspondent.* We do not find any fungus. The appearance may be due to frost attacking the young leaves.

Bud in Axil of Leaf of Tulip: *G. H. D.* Not an uncommon occurrence. A bulb is only a bud, and if at this season you will look at young growing shoots you will find such a bud in the axil of many of the leaves.

Cucumber Leaves: *M. G.* We do not find any insect or fungus on your leaves. The appearance is due to "scald," probably produced by syringing when the sun is out, or from deficient shading, or perhaps from bad glass.

Dendrobiums: *D. McK.* It is not possible to name such miserable scraps which, wrapped in cotton-wool, have passed through the post in a letter, and, of course, were smashed and shrivelled out of recognition. Such things should be packed in a tin or wooden box, in green-moss or sphagnum-moss, or in moistened blotting-paper, they then travel in good condition.

Dendrobium infundibulum: *R. R.* In your flower there are two sepals and two petals, all regular, and placed cross-wise. It is a case of reduction in the number of parts, and of regular peloria, the segments being all equal.

Hyacinths: *X. Y. Z. No.* 4. The disease on Hyacinths is due to a fungus, Uromyces scillarum. The clusters of black spots arranged in a nearly concentric manner are characteristic. The same fungus occurs on the Wild Hyacinth, and has probably come from the woods into the garden. To check, spray with potassium sulphide (½ oz. to each gallon of water), or Bordeaux Mixture, beginning as soon as the shoots show above ground, and continued every two or three weeks. *W. G. S., Leeds.*

Insects: *O. E. G.* Sirex gigas, injurious to growing trees.

Lilacs: *G. H.* The sport might be propagated by cuttings, or by grafts on the common Lilac.

Mango Cultivation: *L. E. S.* Unless your stove is of great height the plant must be grown as an orchard fruit-tree under glass, that is, restricted as to rooting space, by planting it in a big pot, tub, or walled pit in a border, and pinching the lateral shoots, stopping leaders, and thinning-out weak shoots growing in the interior of the crown. For the first few years, however, allow the plant to develop the frame-work, as it were, of a crown, not practising much restriction either at root or top; this can follow later when the plant is approaching the limits of extension. The soil should consist chiefly of sandy-loam of good quality, and not much solid manure, as aids to growth can be better afforded by manurial top-dressings such as stable-manure, potash, superphosphates, nitrate of soda (a little), or by manure-water. When the plant flowers, means should be taken by shaking them, or applying a pair of bellows gently, to distribute the pollen. The plant will succeed under ordinary hot-house culture, or it would do in fruiting Pine-stove.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—Mrs. H.* The Lotus is L. peliorhynchus (Pigeon's Beak), a native of Teneriffe. We are unable to name the Prunus from the scrap received.—*H. B.* Specimens all shrivelled. 1, Illicium anisatum; 2, Amelanchier vulgaris; 3, Jasminum; 4, Panax species; 5, an Oncidium which is not recognisable in its present withered state.—*Mallow.* 1, Clematis montana; 2, Cerasus; 3, Purple Beech; 4, Acer eriocarpum; 5, Orchis mascula; 6, cut-leaved Beech; 7, Acer Negundo variegatum; 8, A. monspessulanum; 9, Spiræa prunifolia, double var.; 10, Saxifraga sarmentosa. Another time do not send more than six at a time; our time is valuable.—*C. L.* Cymbidium aloifolium.—*X. Y. Z.* Sent in round tin box. 1, Begonia ricinifolia manicata; 2, Begonia argyrostigma; 3, Dendrobium crepidatum.—*H. B.* 4, Panax elegans.—*F. A.* The fungus is Coprinus fuscescens, Schff. *M. C. C.—Lady Cecil Scott Montague.* Morea spathacea, Ker. (Dietes Hookeri, Hook.), native of Cape of Good Hope.—*A. U.* The single-flowered Russian Violet, a variety of Viola odorata.—*L. W. F.* Styrax officinale.—*J. B. H.* Piptanthus nepalensis, commonly called Natal Laburnum.—*W. E. L.* 1, Lotus peliorhynchus; 2, Polygala Dalmaisiana; 3, Cistus ladaniferus; 4, Aubrietia deltoidea var.; 5, Alyssum calycinum; 6, Polygonatum vulgare.—*Heather.* Apparently it is Calluna vulgaris, but it is drawn and out of character.—*J. B.* Leucothoe Catesbæi.—*G. D.* 1, Zenobia speciosa; 2, Berberis vulgaris; 3, Ruscus aculeatus; 4, Spiræa chamædrifolia; 5, Berberis Wallichiana; 6, Ligustrum coriaceum.—*Constant Reader.* Dendrobium tortile.—*R. T. D.* Hyacinthus comosus.—*W. W. J. & Son, Boston.* 1, Allium ursinum; 2, Stellaria Holosteum; 3, Sedum spurium; 4, Saxifraga hypnoides; 5, Asperula odorata. Send a specimen of the shrub.—*F. Prince.* Edwardsia grandiflora.—*Merodon.* Solanum jasminoides; the flowers usually are white when grown under glass, in the open they are tinged with blue.—*C. W. D.* Anemone albana, var. flavescens, Regel.—*F. Bowen.* 1, Lælia purpurata Schroderi; 2, Lælia purpurata of good type; 3, Odontoglossum crispum guttatum; 4, Odontoglossum crispum, very fine; 5, Cattleya Mendeli, good forms; 6, Miltonia vexillaria, very bright in colour and large in size; 7, Cattleya Mossiæ; 8, Odontoglossum luteo-purpureum.

Narcissus: *T. L.* The arrest of growth is very common. In our own garden the same thing occurs regularly every year, but we have not been able to ascertain the cause.

Nine Sorts of Vegetable for Exhibition: *Mrs. S. C. H.* These would differ with the date of the exhibition, but taking August as the month, the nine might consist of Peas, French Beans, Globe Artichokes, Potatos, Round and Kidney; spring-sown Onions, Cauliflowers, Cabbage, and Carrots. Others that would be considered by the judges of less value at that date are, Broad Beans, Parsnips, Early Savoys, Butter Beans, Celery, Beetroot, Runner-Beans, Turnips, and Vegetable-Marrows.

Peaches: *H. A. D.* The leaves appear to be suffering from the Silver-leaf disease, a malady common on Plums and other stone-fruits. It is said to be curable by an application of sulphate of iron to the soil, after lifting the tree in the autumn.

Peaches Dropping: *E. E.* The more probable cause is dryness and exhaustion of the soil, seeing that you have growing in a space of "3 yards square" two Vines and two Peach-trees—space scarcely more than sufficient for one plant. The applications of water may have been insufficient in quantity to reach every part of the border.

Pear Blossoms: *F. L.* The flowers have not been properly fertilised, and are therefore abortive. Another time encourage the bees.

Roses: *J. R.* Apparently Crimson Rambler, and the Double Macartney.

Soil and Insects: *C. S., Ipswich.* There are some immature larvæ in the soil, but we cannot tell what they are. Mustard, in powder, mixed with the soil is injurious to some of these creatures. It can do no harm to try it in your case; or Mustard-plants may be grown and ploughed in.

Tomatos Diseased: *C. J.* The specimens present all the stages of Tomato "Sleepy" disease, as described and figured by Mr. Massee in this paper on June 8, 1895. The following is the treatment recommended in that paper: "Spraying with a fungicide is of no avail, as the roots are first attacked, and the parasite is internal. As much lime as the plants will allow should be mixed with the soil, more especially if the plants are grown during successive seasons in the same beds. If the plants in a house are badly attacked, all the soil should be removed, and the walls, &c., sterilised by a wash of lime. The infected soil removed from a bed should not be thrown out at random, but should be sterilised by mixing with quicklime."

Tomatos and Manure: *W. J. G.* If green cow-dung or any other animal manure be used, it should first be mixed with a large quantity of water in a tub, stood in the sunshine, and allowed to ferment for a week, and if the ferment does not then subside a sufficient quantity of white vitriol should be added to stop it, as too great fermentation spoils manure-water. As an artificial, given along with farm-yard manure, nothing is better than commercial potash, and the next best, wood-ashes from green wood. Kainit might be afforded at the rate of 2 to 3 ounces per square yard.

Tulip: *R. C.* We cannot name florists' varieties. Send to some grower.

Tulips: *X. Y. Z. No.* 2. The Tulips are badly attacked in the same way as described in this column last year (May 21, 1898, p. 320). The fungus is almost the same as that which attacks Lilies and Onions (see *Gardeners' Chronicle*, August 11, 1894). Bordeaux Mixture applied early would check the disease, but we doubt if anything short of a thorough clear out will do any good in the present case.

Vines: *C. T. M.* The Vines may be starved, or they were greatly over-cropped last year; more than that we cannot say without seeing the Vines.

IMPORTANT TO ADVERTISERS.—*The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,*

MORE THAN DOUBLED.

Advertisers are reminded that the "Chronicle" circulates among Country Gentlemen, and all Classes of Gardeners and Garden-lovers *at home, that it has a specially large* Foreign and Colonial Circulation *and that it is preserved for reference in all the principal Libraries.*

THE
Gardeners' Chronicle
No. 650.—SATURDAY, JUNE 10, 1899.

SEA-SIDE PLANTING.

BEING a resident on the south-coast, and acquainted with the very varied shoreline from Cromer to the North Foreland, and from there to Beachy Head, I think, perhaps, my experience of the trees and shrubs suitable to plant in such exposed positions may be of interest to your readers, so I will endeavour, following up what was stated in your leading article on p. 338, to impart what I have learned by both success and failure, as regards the decoration of sea-fronts from a landscape gardener's point of view.

With more or less wisdom, local authorities in sea-side resorts are expending thousands of the ratepayer's money on the improvement and decoration of their sea-fronts. Few, if any, of these bodies know anything of even the first principles of applied botany, and thus we have grievous and expensive mistakes too frequently made in seaside planting, even where the advice of a skilled gardener is not wanting. I could cite many instances of this, the year preceding the Jubilee celebrations being prolific in such hastily-planned and ill-judged work, for thousands of fine specimens of trees, Conifers, and shrubs were, as one may say, offered up as sacrifices before the throne of royalty, only to linger on a miserable existence, and finally to end on the rubbish-heap, or furnace of the dust-destructor.

It would be unfair to particularise, as all more or less fell into error, and wasted good material and money on useless planting of salt-spray wetted banks or storm-swept shores, with ill-chosen and improper subjects, drawn indiscriminately from Surrey or even metropolitan nurseries. They have been purchased generally by the borough surveyor or some member of the corporation, who poses as an authority in such matters; for it is a fact, though painful to relate, that the advice of a nurseryman, who has lived a long life at the seaside, and bought his experience dearly, is rarely if ever taken, and thus many grave errors are perpetrated that might have been avoided. One instance I will cite, where "the authority," aiming to avoid disturbing the concrete of the parade, went to the great expense of having a lot of large tubs made, painted green, with black hoops and handles. In these were planted a mixed collection of Conifers, evergreen and deciduous shrubs, which had been prepared for the work, and when these had to a certain extent established themselves, they were early one morning placed at intervals along the sea-front, to the admiration of the visitors and residents, who, in their ignorance, thought the difficulty of adorning the esplanade solved. There were Golden Elders in grand colour, Lilacs showing flower, Conifers of handsome pyramidal habit and growth, and of varied shades of green and gold, and the useful Japan Euonymus, both golden and green-leaved—indeed, a very creditable lot of plants.

Old hands shook their heads and said little, but the young knowing ones were quick to exclaim, "Very pretty, but wait till we have a strong south-west gale, and then see what you think of it!" Alas! too soon black clouds piled up in the west, and presently it began to blow with increasing violence till the next morning, when a sad sight met the view of the early-risers. The soft-leaved, deciduous shrubs were bared on the wind side, the Conifers and most of the evergreens browned and discoloured, the Japanese Spindle-trees (Euonymus japonica) being the only subjects that escaped, while even they were discoloured and broken.

This was repeated in many of the coast towns of our sea-girt "tight little island;" and even when the planters had thoughtfully placed a Tamarisk hedge, or sheltered the shrub borders with large meshed sheep-netting, the shrubs were only partially saved. We may learn from this, first, that a lasting and efficient shelter must be secured, and then only the well and truly tried hardy shrubs planted, if success be courted. As a hedge or shelter there is nothing so dependable as the Tamarisk, the small, dense-growing kind known as T. gallica, being best for this purpose; though the so-called German Tamarisk, Myricaria germanica, forms pretty, free-flowering, single specimens, where planted separately. Yet another of the genus coming to us from the African shores of the Mediterranean is larger in all its parts, but is not so hardy as the two first named. These are easily propagated by cuttings taken of the ripe wood, and to form a shelter should be planted when about a foot high, nine inches apart in a single row, or a foot apart if a double hedge is contemplated. When established, cut down to 6 inches, and in a very short time you will have an effective hedge, which will only need an occasional trimming to keep it neat and serviceable, when it will take care of itself. T. gallica certainly forms the best hedge of the three varieties, and is an elegant and graceful growing plant. A lady friend of mine, dilating on the wonderfully mild climate of Bournemouth, said in my hearing, "Why, they make hedges there of the Asparagus Fern," this being the common name of Asparagus plumosus; but when I had the chance to put a leading question to her, "Have you seen it flower?" she quickly replied, "Oh, yes, it flowers in little spikes of pinkish or salmon flowers at the tips," and then I knew it to be simply the Tamarisk, which, though it may not be quite so light and elegant as the Asparagus, is certainly graceful.

Allied to the Potato, another plant must take the second place as a shelter or hedge plant, namely, Lycium barbarum, known in the country as the Tea-tree. This may be frequently seen planted by the porches of cottages, where it forms a leafy screen in summer, and after giving its grey-blue blossoms in profusion, is in some seasons covered with small, Plum-like fruits, coloured red, like Tomatos. It grows very rapidly, produces suckers abundantly, and will stand frequent trimming, so it makes an effectual hedge or screen. Though a salt-laden gale will brown the leaves, yet it soon grows again, while it is so twiggy, and at the same time sparsely armed with woody thorns, that it may be used at the sea-side to make hedges, and as it grows so quickly, it is most useful in the summer to form screens for bedding-plants or tender shrubs in such situations. It may be raised from seed or cuttings at any time of the year, and may be planted alternately with Tamarix in the hedge-line, as it will impart a stiffness to the fence as it gets older and more woody. A variety—Lycium europæum—is much more thorny, but I fear, unless on the south coast, would not survive our winters.

In enumerating shelter-plants, we must on no account forget the Japan Spindle-tree, Euonymus japonica, now available in many excellent varieties, from the small-leaved, stiff, erect-growing type, known as Euonymus sempervirens, to the pretty miniature foliaged sort, called in nurseries "pulchellus;" the only thing possible to urge against it, that even in the South, winters that register anything like 20° of frost, will kill it to the ground, and temperatures of even less severity will cause it to drop its leaves, though it generally recovers before midsummer. Where it thrives, however, nothing we have makes a closer or more elegant hedge or compact screen to keep off cold or strong winds from foliage or bedding-plants during summer, while though it may lose all its foliage in sharp winters, yet its very compact and twiggy growth will always serve to make it a good screen, and by introducing the kind which develops a golden-tipped growth in spring, called by the common folk flowering, or the broad-leaved golden variegated variety (Ovata aurea) into the hedge, the monotony of greenery is broken, and a useful and very ornamental fence formed. The importance of this evergreen is proved by a nurseryman in the South, devoting nearly the whole of his acreage to its culture.

I hate to dogmatise, but think it would be quite safe to state that not only this, but all the Japanese shrubs and trees, especially those indigenous to the north island, are hardy in Britain and Ireland, and coming to us from a land swept by gales from off the seas, they are by environment naturally well-fitted for seaside work.

Before going further it will be best to state that it is always unsafe to use large specimens of any kind for marine planting, as though you may shelter and secure the stakes, yet the wind will take no account of these precautions, and will twist and sway the poor shrubs to and fro, round and round, till they are at last either uprooted, or all the anchoring roots are twisted or severed, and the plant ruined or may be killed. The smaller, therefore, the stuff chosen the better, and my experience also compels me to say, that the rule as to early planting, so wise in the case of inland work, must in our particular case be ignored, so as to let the strong gales of winter and the drying east winds of March pass; and then towards the middle of April up to the end of May do your work, first using your trees and deciduous shrubs, and finishing with the few Conifers, and lastly the evergreen shrubs.

No doubt, knowing ones among the local authorities will severely criticise, and remark, "You are supplying poor, undersized stuff;" but try and turn a deaf ear to all this, and "gang yer ain wa'," as my Scotch friends say, for in the end you will be right.

Having provided a little for screening with low banks and hedges, let us now take the Conifers, of which very few thrive by the sea. Among Pines, as its name indicates, Pinus Pinaster or maritima ranks first, but, unfortunately, this is such a bad subject to transplant, that from the open ground nothing over 1 foot in height is safe, and if in pots, 2 to 3 feet is ample; but in the latter case, let the planter beware, as in the majority of cases such plants will be corkscrew rooted, and so may blow out of the ground unless securely staked for a year or two. Next to this ranks the Pinus Laricio, a far more handsome Fir from Corsica and the Mediterranean coast; and thirdly, the dark and handsome Pinus austriaca, but this must be planted quite away from the spray line, or it gets browned and unsightly. [In our experience this is the best of the Pines for seaside work. ED.] The Scots Fir (P. sylvestris) does not thrive by the sea in the south, though its dwarf sub-variety, called in nurseries Pinus montana, will grow where not exposed directly to the sea-breeze. [Among true Pines, P. inops, P. contorta, and P. insignis, do well on the south coast. ED.]

Of all Conifers that really thrive on our coasts, none exceed in luxuriance and beauty Cupressus macrocarpa, or Lambertiana; though under the latter name, I grew a much brighter green shrub than macrocarpa for years, the stock-plants of which, if my memory serves me, came from the late Mr. T. Cripps, of Tunbridge Wells.

This was certainly different from macrocarpa, grown side by side in the nursery, not only by its brighter green colour, but its more slender and compact growth. Whatever we may call it, there can be no doubt of its suitability for seaside work, its only drawback being that it is very apt on rich soils to become top-heavy, the root not having fibre enough to anchor it firmly, unless it be planted on a rocky stratum, when, as our editor suggested in a former paper of mine, the woody, tough roots find their way between the crevices of the rock, and firmly hold the Cypress in the soil. This fault is often aggravated by using plants that have made corkscrew roots in their nursery pots, and such, even with the most careful planting, are apt to be blown over by strong winds, even after some years have passed since the planting. Select, therefore, small specimens of this Conifer, and so avoid after-disappointment.

The Nootka Sound Cypress, Thuiopsis borealis of nurseries, Cupressus Nootkaensis of Veitch, is a good Conifer where it can be planted in a position not too much exposed to sea gales, and forms a diffuse though elegant pyramidal specimen where it is allowed space to develop; but a more compact, and perhaps quite as hardy shrub is the Chinese Juniper (Juniperus sinensis), and a sub-variety of the Red Cedar (Juniperus virginiana), called J. Schotti, seems to battle with and resist salt-laden gales very fairly.

To finish the Conifers, mention must be made of the Japanese Retinosporas; if we except the soft plumose section, all can be planted near the verges or paths, and make a most effective finish where the glaucous blue kinds, as Retinospora ericoides is contrasted with golden-tinted sorts, as "obtusa nana aurea," "Tetragona aurea," &c.

None of the Yews are entirely satisfactory, though the Japanese and Korean varieties of Podocarpus have stood well in most cases, and the Prumnopytis elegans may be planted here and there to give grace and variety to the work.

Now come the numerous evergreen and sub-evergreen shrubs, and for the south and west coast, as has been before stated, nothing surpasses the Euonymus japonica, all the varieties of which should be used, the erect growing green and variegated sorts as single specimens, and the green and variegated species — radicans, and radicans variegata, utilised as neat edging plants, or where rockwork is introduced, or rocky banks utilised, and I certainly approve of this wherever practicable; plant these in every available pocket or crevice left between the stones or boulders. Among the very best of the first-named, select Euonymus ovata and ovata aurea, but the silver-margined sort is very tender, and is, indeed, no great acquisition. A new kind, called on the Continent Sieboldiana ignota, though carrying very handsome large leaves, is only fit for the cool conservatory or orangery. Scarcely one of the Laurels is entirely satisfying, but the two best are called caucasicum and rotundifolium. The Aucuba japonica should only be planted where it can have partial shade and shelter, and then the green forms viridis (ovata), both male and female, are to be preferred, as they are stiffer and more compact than any other, and when covered with their large red fruits are really handsome.

Among berry-bearing shrubs Cotoneaster Simonsii deserves a place—even when raised from seed they soon make neat little plants, and fruit freely; while for foliage contrast the silvery-leaved Orache, Atriplex Halimus and portulacoides, or canescens, which may with advantage be dotted here and there among the green shrubs. *Experience, May* 30, 1899.

(To be continued.)

ORCHID NOTES AND GLEANINGS.

LÆLIA PURPURATA SCHRODERI.

THIS puzzling section of Lælia purpurata, so widely different from the type, has caused some to regard it as a distinct species, or probably a hybrid of L. grandis. The late Professor Reichenbach's L. Wyattiana is very close to this, and the intermediate forms between it and the typical L. purpurata leave no excuse for separating either from the species.

A fine flower of L. purpurata Schroderi is sent by H. Cary Batten, Esq., Leigh Lodge, Abbot's Leigh, Bristol. The sepals and petals are white; the lip also white, with a slight rose-coloured tinge in the centre, behind which the tube is tinted pale yellow, with fine, dark purple lines.

CATTLEYA MENDELI.

This is the favourite Cattleya of many Orchid-growers, not only on account of its beauty, but because it is a grateful plant, that always rewards the gardener for the care bestowed upon it. In most collections its flowers are now among the most admired of those in bloom, and many and varied specimens have been received.

One of the most beautiful is sent by Mr. Richard Cairns, gr. to J. M. White, Esq., Balruddery, near Dundee. The sepals are white, with a slight rose flush; the petals are clear white, crimped slightly, fringed, and measure over 7 inches from tip to tip. The handsome lip is yellowish-white on the outside, and bright yellow with rose-coloured lines inside, the front lobe being bright rose-purple. This bloom was slightly injured in expanding, but it promises to be even better when fairly developed. *J. O'B.*

BIFRENARIA HARRISONIÆ ALBA.

The type form better known as Lycaste Harrisoniæ was at one time a prime favourite in gardens, and a good plant for an exhibition. As with many other Orchids, when white varieties appeared the words "alba" and "eburnea" were applied, although all such flowers possessed more or less of rosy-purple tints on the lateral lobes of the lip. Recently there appeared in Sir Trevor Lawrence's collection, a form with fine clear white flowers possessing a yellow tinge on the lip and callus, and for this variety, distinct though it was from the original, the name "alba" was retained in order to avoid a needless multiplication of names. A fine inflorescence and of a similar uniform, clear white, has been sent by Joseph Broome, Esq., Sunny Hill, Llandudno, who also sends a magnificent Cattleya Schilleriana

DENDROBIUM NOBILE VIRGINALE.

A flower of this beautiful albino of Dendrobium nobile, sent by Mr. Edge, gr. to J. Leemann, Esq., West Bank House, Heaton Mersey, shows what was at one time thought to be very improbable, viz., a fine clear white flower, without any other colour than a tinge of pale yellow on the lip. The flower is large, and of excellent shape, and it measures nearly 4 inches in width, with petals at their broadest almost 1 inch in width. The growth of the variety is said by Mr. Edge to be free, so that an increase may be looked for shortly. The bloom is identical in shape with the only other albino of D. nobile, viz., D. n. Ashworthianum, illustrated on p. 203 of the *Gardeners' Chronicle* for April 2, 1898.

ALPINE GARDEN.

ANEMONE ALBANA.

OF the Anemones belonging to the Pulsatilla section, all of which are desirable in gardens if they will flourish, I have found none so satisfactory in its habit and the readiness with which it adapts itself in my garden to any conditions and surroundings, as one I have cultivated for many years as A. albana. I think it first came from seed sent by Mr. W. Thompson, of Ipswich. It is a dwarf plant with much-divided leaves, like the native A. Pulsatilla, and flowers about the end of April, when grown 4 to 6 inches high. The flowers are nodding, in the form of a cylindrical cup, somewhat compressed towards the mouth, and are produced very freely; this year their abundance is remarkable, on one clump, not more than 9 inches across, there are now about 100 flowers and buds. The plant does equally well on the rockery and the level border, but like the rest of its class, prefers an exposed site. The seed-head, like that of all the Pulsatillas, spreads into an ornamental tuft, and seed ripens in abundance, comes up readily, but does not flower till the third year. The colour of the flower is uniform dull ochreous yellow, leaving much to be desired for brightness, but in spite of this defect, the excellent habit, causing the plant at every stage to look neat and healthy, makes it acceptable in spring, and it lives in the same spot for many years.

Having enclosed specimens to verify the name, I may add a few words concerning its rather doubtful identification. A. albana (Steven), named, of course, from the Caucasian Albania, is not found in Europe, but extends all across Central Asia, from the borders of Armenia to the south-eastern limits of Siberia, being so abundant on the confines of Thibet, that the note of a recent traveller there describes the area of his tent as entirely carpeted with it. It is exclusively a high mountain species, differing in this respect from A. pratensis, to which it is nearly allied, but which is a lowland plant. In Hooker's *Flora of British India*, vol. i., p. 7, A. albana (Steven) is described as not descending below 15,000 feet on the Himalayas, and as having flowers of "dull red-brown." Sir J. Hooker considers it "probably an alpine state of the European A. pratensis." E. Boissier (*Fl. Orientalis*, vol. i., p. 10) gives A. albana (Stevens), "floribus flavidis et cœruleis" (yellowish and blue); whilst De Candolle, who assigns the same wide area to the species as Hooker and Boissier, gives (*Prodromus*, vol. i., p. 17) A. albana (Steven) "flores albidi aut ochro-leuci, nec purpurei (flower whitish, or dull yellow, and not purple). I have never been able to obtain a purple-flowered A. albana, and am curious to know whether the Herbarium at Kew contains any purple specimens. Also whether there are any in that collection of the colour described in *The Flora of British India*. A. albana, with purple flowers, if it retained the habit of the dull yellow form, would be an acquisition worth having for gardens. *C. Wolley Dod, Edge Hall, Malpas.* [There are several specimens of A. albana with purple or violet flowers in the Kew Herbarium, and on the whole their flowers are rather larger than those of the typical ochreous form. The Indian plant is noted as being purple on one label. ED.]

THE FERNERY.

BRITISH FERNS FOR CONSERVATORIES.

WALKING round my fernery at this season of the year, and noticing the rapidly unfolding beauties of the numerous varieties, their freshness, delicacy, and multiformity, it becomes more and more a puzzle to me that so few people avail themselves of these lovely native plants in their varietal types, while so many use the common ones. Although I must plead guilty, if guilt be in question, to the enthusiasm of the specialist, which sometimes implies blindness to demerits as a set-off to keener appreciation of merits, I cannot, for the life of me, conceive an adequate reason for the neglect which this beautiful branch of native horticulture undoubtedly suffers. That they are not in favour with the nurserymen is certainly a factor in the problem. Exotic Ferns, which can be rapidly brought into marketable form under warm culture, pay them better to raise than do hardy ones, which resent forcing, and take, consequently, much longer to develop. The fact, too, that British Fern-fanciers form a sort of clique, prone to swell their collections by exchange rather than by purchase, is another thorn in the side of the trade, and a consequent impediment to that popularisation of the plants which trade hands achieve by advertisement and exhibition, when the demand justifies both by profitable results.

There was, however, a time when neither of these factors, nor both of them together, sufficed to check business. British Fern varieties were the fashion, just as Orchids are now; new things fetched fancy prices, buyers were plentiful, and the gems of that day were installed in places of honour in garden and greenhouse all over the country. Fashion, however, is a fickle thing; and presently, due largely, I believe, to the swamping of the market with indiscriminate seedlings, ugly curios rather than "things of beauty," a reaction sets in, from which the plants still suffer.

I am confirmed in this view regarding the quality of the Ferns sent out, by perusal of Sims' catalogue of the time, in which descriptions which set my teeth on edge prelude prices which, were I a seller, would make my mouth water. The veriest rogue seedlings, depauperate abominations, have several lines of description, and portentous names, and taking the whole catalogue from end to end, I am safe in saying not 10 per cent. were worthy to survive pricking out. In point of fact, it is since that period of fashion that the best things have been found or raised. In the interim a coterie of constant admirers has stuck to the cult, some adding to the store of gems by assiduous hunting in ferny localities; others by raising and selecting on stringent lines, and some doing both; the end results being a considerable elimination of the worthless, and such an enormous addition to and improvement of the really symmetrical and beautiful forms that no comparison can now be instituted between the best of the "fashion" period and the best of to-day. Quietly, and, as it were, behind the scenes, the connoisseurs have been busy ever since, and the result is as great an advance in form and quality in our native Ferns as has been attained in floriculture during the same period, which is saying a great deal. This advance, too, has been all along the line, and not confined to one or two species or varietal branches. The Hart's-tongues, Lady Ferns, Male Ferns, and Shield Ferns, have all participated in selective improvements, and contributed their quota of superior finds.

I do not propose to myself to enter at length into these in this article, but rather to emphasise the fact of their great excellence, and the pity that thousands of cool conservatories, unfitted by their exposure for the proper growth of flowers, are not devoted to the culture of these charming substitutes. In these days of extension of brick and mortar, most of it necessarily on formal and restricted lines, the attached conservatory is very often an adjunct, quite independent of fitting aspects. The houses in a road face north and south, and the conservatories do the same, half of them, of course, getting but transient glimpses of sunshine, or none at all. Here is the ideal British fernery. No hot-water pipes are wanted, for the plants are as hardy as grass, the constant shade, death to flowers, is life to Ferns, and with a judicious arrangement of staging, and perhaps a little rockwork, a few dozen good varieties will give a maximum of pleasure with little trouble. If space be limited, there are dwarf congested forms to fit; and if be extensive enough, grand specimens of the larger kinds do yeoman's service in the way of decoration. It is, indeed, one of the great charms of our British varieties that their size has so great a range that within one and the same species we may have full grown dwarf specimens, condensed gems an inch or two high in thumb-pots, cheek by jowl with grand relations 3 or 4 feet long in the frond, and spreading into as much, or more, in all directions. Lastrea pseudo-mas cristata as the giant, and L. p.-m. crispatissima in the Male Ferns, Athyrium f.-fœmina var. percristatum, and the diminutive Edwardsii, among the Lady Ferns, and a finely grown specimen of the crispum Hart's-tongue side by side with S. v. Kelwayi densum, a tiny ball of moss, are all examples of this, and there are all grades between.

Where space is restricted and accommodation scanty, a single species, like the Hart's-tongue, would suffice to stock the place, and be replete with interest, so versatile is the species; while the average size of specimens is moderate enough to admit of a greater number of forms than the other species named would allow many to their greater spread and dimensions. To those who have such shady conservatories, I strongly advise the acquisition of a few good varieties; not the common Ferns hawked about the streets, or ignominiously boxed and bundled under nurserymen's shelves; these are simple Nature's raw material, and in this connection are to be severely let alone, as a check upon the Vandals. Pot the acquisitions carefully, water them properly, keep them steadily one way to the light, not twisting and turning them about, as is often done, to their inevitable distortion and spoiling; and I am sure they will repay the care bestowed far and away better than sickly lanky Pelargoniums or other flowers which too often occupy such situations, and repay their cruel owners by a liberal crop of greenfly in lieu of other verdancy. In the one case we suit the tenants to the environments, since Ferns are eminently shade-loving plants; in the other, we are at war with Nature, since flowers are the children of the sun. The excuse, therefore, of flowers or nothing, falls, as we have seen, to the ground, unless the individual be so wedded to bright colours, that the quieter harmonies of frondage, and its delicate tracery and tasselling, be altogether thrown away upon him. In that case we shall never make him a convert, for it is pre-eminently "the harvest of a quiet eye" that repays the British Fernist. *Chas. T. Druery, F.L.S., V.M.H.*

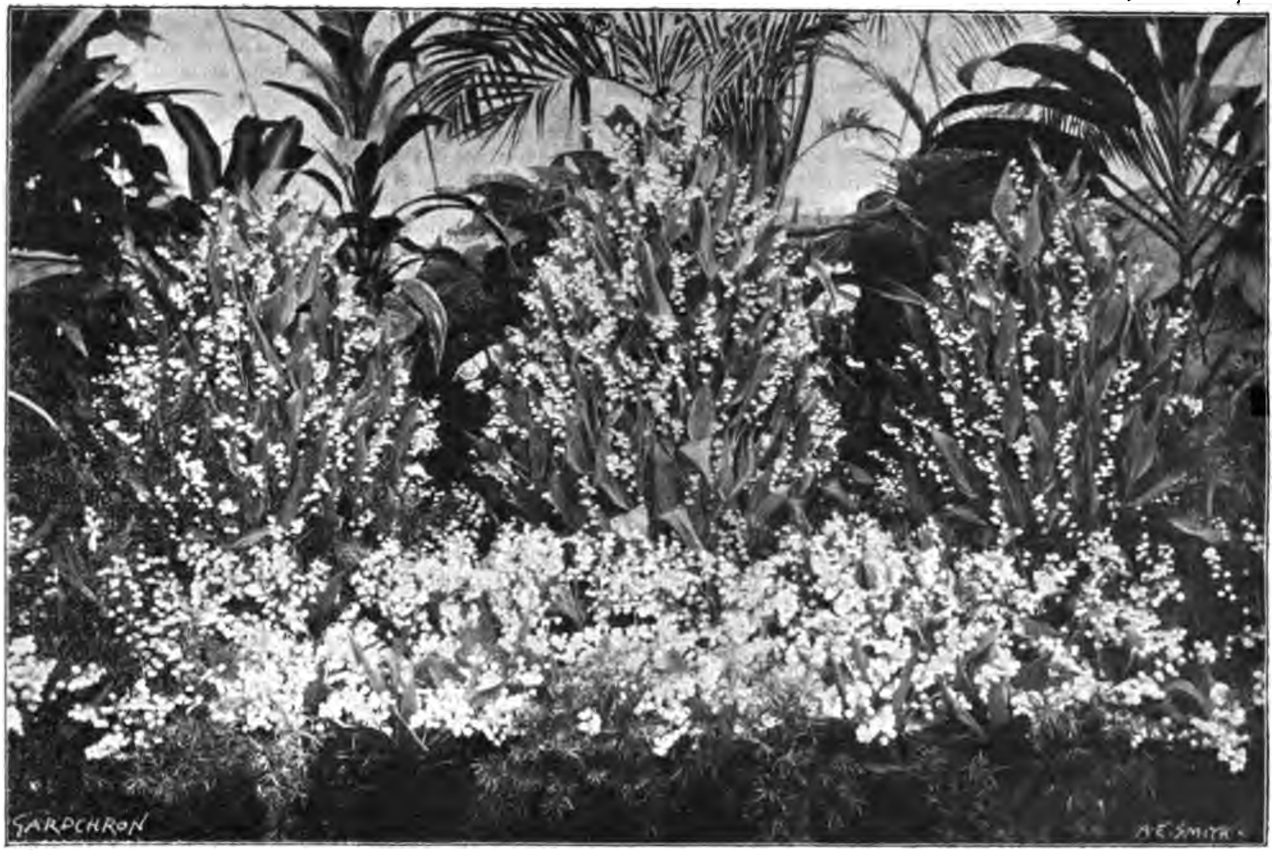

FIG. 130.—RETARDED LILY OF THE VALLEY.

(Exhibited at the Temple Show by Mr. T. Jannoch, Lily Nursery, Dersingham, Norfolk.

NOTES ON WYASTONE LEYS.

Tourists and others who have passed through the Wye Valley by rail may have noticed between Symonds Yat and Monmouth, a pretty stone residence standing upon a plateau on the steep west bank of the river surrounded by well dressed grounds, and backed up by high rocky hills, furnished with specimen trees and shrubs. The mansion referred to is Wyastone Leys, and belongs to J. M. Bannerman, Esq. Few seats naturally possess such grand surroundings, and command such views as does this. The magnificent stretch of scenery to be seen from here, embracing as it does some of the most beautiful to be found in Monmouthshire, Gloucestershire, and Herefordshire, is a grand spectacle; while near at home the Wye Valley itself, which, with its silvery river, rich pastures, and rock, and wood-clad banks, can be viewed both up and down for a considerable distance, affords a charming picture.

The most attractive feature in the gardens at the time of my visit was afforded by hardy bulbous plants, which are used in great numbers and variety, and under various conditions. The exceeding freedom with which they blossom proves that the light, rich, and warm soil of the place, meets their requirements in every way. Many of them have been undisturbed for years, and have formed large clumps. This refers particularly to Hyacinths, Tulips, Triteleias, Anemones, Fritillaria imperialis, Leucojums, Muscari, Scillas, Jonquils, and Narcissus (Daffodils, poeticus, and Polyanthus) in many varieties, which make a gorgeous display mixed with herbaceous plants in the long borders; N. Macleaii, a small white-flowered species with a bright yellow crown, struck me as being particularly pretty and distinct. A pleasing effect was produced by Narcissus in variety, by Leucojums mixed freely with Primroses on the grass amidst specimen trees and shrubs, upon steep banks, and in natural bays at their feet; this is carried out in a way to imitate nature, and with success. It deservedly merits copying, although it is not in every place that the character of the ground would enhance the effects as is the case here.

The undulated contour of the land is admirably suited to display the beauties of flowering shrubs, but my visit was paid too early in the season to see many of these in blossom; nevertheless, groups of Forsythias and some early Rhododendrons were conspicuous, and some tender genera not often met with were observed growing amongst ordinary shrubs, where they have been for years. Of these, Exochorda grandiflora (syn. Spiræa grandiflora), indigenous to China, was flowering freely; its choice white blossoms are very sweetly scented. Piptanthus nepalensis, a handsome leguminous shrub from the Himalayas, was unfolding its beautiful racemes of yellow flowers, which were produced in abundance. It was growing in a sheltered situation, and many seedlings from it had sprung up around. Choisya ternata is perfectly hardy here—at least, several big healthy bushes, thickly beset with flower-buds, have been for several years in their present open positions.

I may mention that under glass Maréchal Niel and Niphetos Roses, planted in borders and trained near the glass, were flowering splendidly. Complaints about the constitution of the former are often made, but here a sturdy plant has been in its position for at least twenty-five years. I was pleased to see some old, commonly neglected plants valued and well cared for, such as Begonia corallina, a handsome woody-stemmed species, possessing clusters of coral-like flowers, and growing as a pillar-plant; while B. fuchsioides was used in a similar manner, and was almost equally beautiful. Amongst Orchids, some plants of Vanda teres, planted in groups in crocks and sphagnum-moss placed in shallow boxes and baskets, were vigorous, and thickly furnished with flowers on the point of opening. They are grown, as is the usual practice now, fully exposed to the sun.

Tomatos in a low house were particularly well grown; the varieties were All-the-Year-Round and Ham Green Favourite. The former, which has medium-sized fruit, in large clusters, has proved to be an exceptionally prolific winter-fruiting variety; Ham Green, although not so free-bearing during winter as its companion, has large fruit, and is reliable in summer. Royal Sovereign Strawberry, growing in pots, were carrying fine crops, some of them being ripe, large, and well coloured; and the trees in an early Peach-house were bearing heavy and regular crops of fruit.

The garden in each department denotes that it is skilfully managed by Mr. Phillips. *Thos. Coomber.*

FLORISTS' FLOWERS.

SUMMER-BLOOMING VIOLAS.

I still hold that the best summer results come from plants put out in August or September of the previous year, or even earlier. At the present time, I have most effective clumps a foot in diameter that are masses of bloom, and with a top-dressing they will continue to flower freely all the summer. They are plants which were planted in the open a year ago, and they are in a fairly stiff soil, in which they root deeply and freely. In the case of a light soil, it would be best in some cases to trust to younger plants put out in March or April. When plants are placed in the beds or borders as late as April and May, unless they are encouraged in every way, they fail to get a deep hold upon the soil before hot weather sets in, and they frequently fail when their service is most required. My contention is illustrated in a striking manner in Messrs. Veitch & Sons' Langley Nursery. There are two borders of Viola Blue Bell, one on either side of a broad walk; these plants occupied this position all the previous winter, but the variety goes on flowering right up to the autumn. It is these qualities of persistency and continuity that are wanted in too many of the new varieties. It appears to be thought that the main use of the Viola is for exhibition, and not in the flower garden. New varieties are so disappointing that I have given up buying them. The old sorts hold the field for bedding purposes—Countess of Hopetoun, J. B. Riding, William Niel, Bullion, Sylvia, True Blue, Duchess of Fife, &c. What is wanted is a systematic trial of all the leading varieties; the whites by themselves, so as to afford close comparison; the yellows, and other colours or combinations, similarly treated; and the plants put out in September, so as to afford a good winter trial of endurance. But this trial should be carried out in an open, breezy spot, away from the effects of London fogs. As fogs prove harmful at Chiswick, no such trial can be attempted there. *Florist.*

Auriculas in Pots.

Auriculas were in many cases quite late in flowering this season—in the last week of May. I have such fine alpines as Fred Knighton, Magnet, Winnifred, and Sunrise, only just in flower, but that may be owing to my plants being in a north house, and getting but little sunshine. Fred Knighton is a grand late alpine, large, of the best form, and brilliant in colour. But there are many fine alpines now, and though Mr. C. Turner has somewhat dropped out of the field as a raiser, Messrs. Douglas, Phillips, and others, are active in adding to our lists. We are strong in golden centres, but still a little weak in white centres. The two best I have bloomed this season, are Desdemona and Winifred, both raised by Mr. Turner; they are white centres, and the white lasts well, while the marginal colour is fresh and brilliant. The late Mr. J. Gibson, of Reading, raised several alpine varieties, but as he had set up a high ideal, he put aside flowers that others would have had no hesitation in naming. He sought to improve the white centres, using Winifred both as a seed and pollen parent; and a few of his seedlings came into my possession at his death, the best being Tillie. This is a very large, finely-formed, stout flower, with a broad and massive, deep-shaded purple margin, and a living white centre; the contrast is remarkable, but the white centre is a little narrow in its diameter. It promises to make an exceedingly useful seed-parent. It is to be hoped that we shall soon see the last of the confused creamy-white centres, on some of which the young and the old flowers show two distinctly different stages of development. Many seedlings otherwise good have to be rejected on account of this defect.

The notched segment of the corolla is rapidly disappearing. It lingers longer in the case of the white centres, and especially with those of the most delicate mauve and purple tints. All white-centred flowers—those whose centres are really white—are frequently of thin substance. We want the solidity which characterises Mr. Gibson's Tillie; we want also the diameter of the centre to be equal to the zone forming the margin.

There is a tendency in some of the newer seedlings to show a wide, irregular, gaping tube. While the tube is not of such first importance in the case of the alpine as in the self and edged show varieties, it should yet be equal to the other parts; and a gaping tube breaks into and robs the centre of its proper proportions. The scape supporting the truss is rather long in some of the new varieties, a fault conspicuous in the case of the beautiful blue self Mrs. Potts, but that will be remedied in course of time. Some may regard these points as trifles, but it should be remembered that the Royal Horticultural Society has set up an authoritative schedule of qualities in the Auricula, and it should be the aim of raisers to approach as nearly as possible to them. They are, therefore, not trifles; and to any objector it may be said, "Trifles make perfection, and perfection is no trifle."

The alpines which now win at Auricula shows are more or less shaded. The self colour is required in the show type; it is a form of incompleteness in the alpine; as the white or golden centre should be surrounded by a margin, shading from dark to light. Self alpines were recognised when there were but few named varieties; now the latter are many, and there is no need to fall back upon the self. As any shading on the show self is a grave defect, so the self colour is a grave defect in the alpine. This is the recognised difference between the two types. *R. D.*

NOTES FROM A SCOTTISH MANSE.

(Continued from p. 275.)

During the last fortnight I have had the great privilege of visiting many places of horticultural interest; such, for example, as the Royal Gardens at Windsor, where the fruit grown under glass is the predominant attraction, and where for the first time I saw growing the Banana, one of the most valuable of tropical fruits. I much regretted, on that occasion, the absence of Mr. Owen Thomas, who had gone to London to superintend the floral decorations of Buckingham Palace, during the temporary residence there of Her Majesty the Queen; but I received great kindness from his lieutenant, Mr. Edwards, and his intelligent assistants. I was somewhat surprised to learn that the Almond-tree is not grown in the Royal Gardens, for this is by far the most beautiful of spring-flowering trees. I also visited the Royal Nurseries of the Messrs. Turner at Slough, still famous, as of old, for Carnations, Roses, and Pelargoniums; the great Orchid establishment of Mr. F. Sander at St. Albans, and the splendid collections of the Messrs. Veitch at Chelsea, both of which are veritable epitomes of the flora of the world. I also saw once more, and greatly admired, Mr. Wm. Bull's Orchids; and Mr. William Paul's Roses at Waltham Cross, some of which were subsequently exhibited with grand effect at the meeting of the Royal Horticultural Society in the Drill Hall, Westminster, where I had the pleasure of meeting, for the first time, with one of my kindest friends, Mr. Harry J. Veitch.

Before leaving the Modern Babylon, I made a pilgrimage to Surbiton, one of the most charming places in Surrey, where, at the Long Ditton Nurseries, Mr. Wm. Barr, of Covent Garden, showed me his Darwin Tulips, the hybrid Narcissi, including "Victoria," and other highly fascinating flowers.

On my return to Kirkmaiden Manse, I found my own garden in wonderfully good order, considering the fact that during my absence (which, however, was not long), my industrious gardener had, like some of the English soldiers who fought at Prestonpans, been wounded by a scythe, though in a somewhat different and more accidental way. Now, however, that he has recovered his wonted energies, and has my assistance, things are assuming a brighter appearance, and the flowers find themselves in perfect harmony with their surroundings. Nothing impresses me more at present than the rapid development of Lilium giganteum, the largest plant of which in my possession has been grown from an offset for four successive seasons, and will bloom this year. It is a very powerful specimen, and promises to attain to a commanding height. The development of this giant is such as to astonish all visitors to my garden. This is owing, no doubt, largely to its nature, for the characteristic of which I speak is one which I have observed in dryer and sunnier seasons than this; but doubtless its growth has also been considerably accelerated by the recent heavy rains, which have been followed providentially by brightest sunlight during the last few days, though the wind keeps cold. Lilium giganteum, which is of Himalayan origin, has this peculiarity: that in the production of its immense stem and majestic flowers it exhausts the massive bulb; but it is perpetuated by offsets, whose energy in the generation of foliage is quite visible before the aspiring parent of these comes into bloom. I have several other Lilies which have grown with almost equal rapidity; especially the Chinese Lilium Henryi, originally discovered by Dr. Henry. Lilium speciosum Kraetzeri, which will come into flower very early this year, and several stately specimens of Lilium auratum, which, I anticipate, will bloom in July.

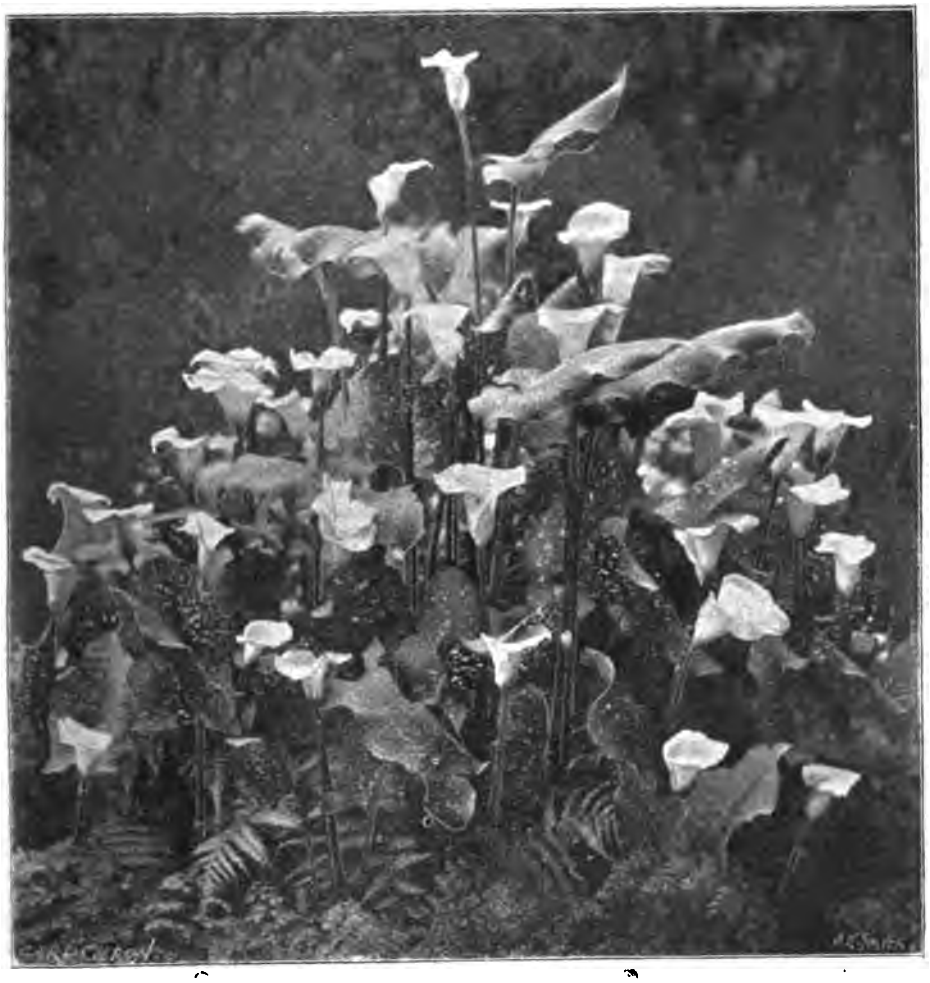

FIG. 131.—A GROUP OF RICHARDIA ELLIOTIANA: COLOUR OF THE SPATHES BRIGHT YELLOW.

(Exhibited by Messrs. W. Cutbush & Son, Highgate, at the Temple Show.)

My Spanish Irises, so long seemingly inactive, my Ixias and Sparaxis—beautiful flowering plants of African extraction—are beginning to show definite signs of activity; and I hope to have their bright beauties contemporaneously with those of Lilium candidum, one of the fairest and most fragrant Lilies of the garden, and with the first efflorescence of the "regal Rose." There are many eminent professional horticulturists who have hitherto made no attempt to cultivate Ixias, because they regarded them as delicate plants. I find, however, that they preserve their foliage marvellously during the winter, and are not much affected, much less than the Montbretias, by the vernal frosts. Of almost equally vigorous constitution are the Californian Calochorti, of which the finest (and latest) are the gloriously-tinted "Mariposa Lilies," which flower in July. But even the earlier forms, though less exquisitely painted by the hands of gracious Nature, are exceedingly interesting. They may have an affinity to the family of Tulips, but they offer a very striking contrast to these.

The foliage of many of my Roses is at present so beautiful, that flowers seem to be almost superfluous for artistic effect. Supreme among these are such decorative varieties as Madame Joseph Combet, Mrs. W. J. Grant, one of the grandest of the Newtownards introductions; Madame Laurette Messimy, Madame Charles, and the luminous La France. In this season of sunshine, growth, and brightest hope, it is difficult to realise the words of George Herbert:

> "Sweet Rose, whose hue angry and brave,
> Bids the rash gazer wipe his eye;
> Thy foot is ever in the grave,
> And thou must die."

The reign of the Narcissi, so long and so beneficent, is nearly over; but the intensly fragrant Narcissus poeticus is with us still. *David R. Williamson.*

APPLE SPRAYING IN NOVA SCOTIA.

Potash Spraying, to clean the bark of moss and lichen and destroy insects lodging in the crevices of the bark in Canada, is mostly done during April, before the buds open. For this purpose, one third to 1 lb. crude rock or powdered caustic potash to one gallon of water is employed. The men using the strong solution wear old rubber mackintoshes to protect their clothes, and sometimes indiarubber gloves. In some cases a rubber cover is strapped over the horse to protect it. The Apple trees are sprayed all over to the topmost branches, say, 30 feet or more high. If the trunks only are to be washed, this may be done at any time of the year, either in early spring or, perhaps better, about May or June, when the young scale insects are hatching out and beginning to move about. A vegetable fibre lime-wash brush is used for this purpose. The effect of the potash-wash is to give the trees a healthy bark. I have seen the trunks of young trees thus treated yearly shining in the sun as if varnished.

Copper Sulphate Spraying.—The object of this is to destroy the spores of "black spot," or "scab," the most serious fungus disease that attacks the leaves and fruit of the Apple, spoiling the appearance of the latter, and causing it to crack, interfering with its growth. Copper sulphate at 3 lb. to 40 or 50 gallons of water is used any time before the buds expand. Later on the sulphuric acid must be neutralised by lime, or the foliage will be burnt.

Paris Green Spraying to destroy chewing insects, such as the caterpillars of the Winter Codlin, Ermine, and Lackey moths.—If Paris Green is used alone it is desirable to add twice the weight of lime to counteract the possibility of any free arsenious acid which may burn the leaf. The purity of Paris Green may be tested by ammonia, which should dissolve it entirely, producing a blue liquid. A quarter of a pound of Paris Green to a 40-gallon barrel of water is the usual proportion used. In using Paris Green one commences by weighing out ¼lb., and then measuring this out in spoonfuls to see how many it is equal to, so as to be able to measure it in future as being less trouble than weighing each time. One places the required quantity in a cup, adding water and stirring to mix it to a paste. Then add it to a pailful of water and pass it through the strainer, adding it to the water or Bordeaux Mixture in the barrel.

Bordeaux Mixture and Paris Green are the most commonly used combined fungicide and insecticide. The proportions generally used are:—

4 lb. copper sulphate,	4 oz. Paris Green,
4 lb quick lime,	40 gallons water.

This is used throughout the season, the first spraying being when the leaf buds are open, but before the flower buds expand, the second after the blossoms have fallen, afterwards at intervals of two or three weeks, if there is appearance of fungus on leaf or fruit, or caterpillars eating foliage. The number of times necessary varies with season and variety, from two to six times.

The usual way of making up the Bordeaux Mixture in bulk is to take a 40-gallon paraffin cask, fill it with water, suspending in it 40 lb. sulphate of copper contained in a sack or basket. This gives a strength of solution of 1 lb. to one gallon. Another barrel is used for the lime, which is slaked and stirred up, forming "lime putty." This is kept covered with a little water. When required for use the 40-gallon barrel to which the pump is fixed is partly filled, say one-third full, with water. Four gallons of the copper sulphate solution are added, and then an equivalent of about 4 lb. lime is stirred up with water and strained through a brass wire strainer at the bottom of a funnel, used in filling the barrel. The mixture in the barrel is stirred, and many farmers test to see whether enough lime has been added, so as to avoid adding more lime than necessary, and possibly clogging the pump. For this purpose a solution of ferrocyanide of potassium (1 oz. in a pint of water) is used. A cupful of the mixture is taken from the barrel, and to this a few drops of the ferrocyanide solution are added. If it turns blackish-brown, more lime should be added; if the sky blue colour is unchanged, enough lime has been added. The barrel is then filled up with water, or if Paris Green is to be added it is now put in.

Soap and Paraffin are used for the destruction of sucking insects, such as aphis, scale and woolly aphis. This is not often used, as these insects are not often a serious pest. Perhaps the best recipe is the Hubbard-Riley emulsion, made by boiling half-a-pound of hard soap in one gallon soft water; add two gallons paraffin, and churn the two together for five or ten minutes. For use dilute this with from four to twenty parts of soft water, according to whether it is used to wash the bark, or as a spray when the tree is in leaf.

The Pumps used are force-pumps, fixed to ordinary paraffin casks holding about 40 gallons. Their working parts are of hard brass, and they have an agitator paddle. Two of the best pumps I saw were "The Pomona," made by the Goulds Manufacturing Company, Seneca Falls, New York, and "The Eclipse," by Morrill and Morley, Benton Harbour, Michigan, U.S.A. A moveable square box funnel with fine brass wire mesh is used for straining the lime, &c. A rubber hose-pipe about 10 to 15 feet long is used, with a bamboo extension rod 8 to 10 feet long (this has a tap, a brass pipe passing through the centre of a bamboo), terminated by a double Vermorel nozzle.

I have recently got over one of these pumps, and shall be pleased to show it to anyone interested in spraying. I have had it mounted on wheels like a garden engine, and it works very well. In the Canadian and American orchards the pump and barrel are generally mounted on a cart or a low light waggon, sometimes with a platform, and drawn by a horse through the orchard, one man driving and pumping, the other directing the spray.

Lodeman writes:—"For well-grown trees 25 years old two to three gallons of liquid are required when sprayed before the blossoms open; later in the season, when the tree is in full leaf, four or even six will be necessary to cover the leaves and fruit thoroughly."

Professor Bailey writes that "with a 300-gallon tank drawn by two horses, with three men, one driving and pumping, the other two standing on the rear platform two or three feet above the tank, directing the spray each with a hose pipe, the pump having an automatic stirrer; with this rig five acres of full-grown Apple trees can be thoroughly sprayed in a day."

All the working parts of the pump should occasionally be oiled, also the nozzles.

In using both copper sulphate and potash, iron vessels should be avoided, preferably using wooden pails. Before working with these liquids it is a good plan to rub the hands over with mutton or some other fat not containing salt. Avoid spraying work when the hands have open cuts or sores, and wash the hands well after work. When spraying it is advisable to wear one's worst clothes. A broad-brimmed (straw or rush) hat is of advantage in shielding the face from spray. Spray from the lee side, and only when calm.

Macmillan & Co., of New York and London, have published an excellent book, "The Spraying of Plants," by E. G. Lodeman, Instructor in Horticulture in the Cornell University. *Cecil H. Hooper.*

THE HERBACEOUS BORDER.

ALYSSUM SAXATILE TOM THUMB.

THIS dwarf "Gold Dust" or Rock Madwort is not by any means a new plant, as it is several years since it was first sent out. When first catalogued, one had pleasing anticipations of a miniature A. s. compactum, covered with golden flowers as freely as the larger form, and suitable for the very choicest places among the alpine flowers. The first season's disappointment was mingled with hope that the sparse flowering was due to the plants requiring time to become established. Succeeding seasons have, however, been almost equally disappointing, so that one can only plead that this note is penned as a warning to others not to expect too much. The stature of A. Tom Thumb is quite well indicated by its name. The flowers are produced in smaller corymbs than those of the typical form, and are individually inferior. The habit of the plant is less vigorous in every way, and its poor blooming properties are even accentuated if not planted in a dry and sunny position. I have found no difficulty in striking cuttings taken off, in the old-fashioned way, with a heel, but some of my friends have been less successful in striking them.

ANEMONE NARCISSIFLORA.

Novelties are very well in their way, and one always welcomes their appearance if at all acquisitions. While this is so, those of us who have the opportunity of seeing gardens of hardy flowers, see that it is frequently necessary to bring before their owners well-proved plants of beauty. Such a plant is Anemone narcissiflora, the Narcissus-flowered Windflower, which, one may safely remark, ought to be more widely known in private gardens. The rockery is the place recommended for it in some standard works on gardening, but it may be quite as well grown in the border as in the rock-garden. As this is written there is a nice plant in bloom in one of my borders, where it has been for several years, and I have occasionally met with it in similar positions, but in a heavier soil. A. narcissiflora is very distinct in its way, with its umbels of upright, white, or whitish flowers, produced on stems from 8 inches to over a foot high.

A pretty feature of some of the forms is the tinge of purple on the outside of the flowers. The whole appearance of the plant is, indeed, attractive, its slightly woolly look and the palmate leaves making it one of some character. It is perfectly hardy, and may be increased by division.

ANEMONE NEMOROSA ALLENI.

I often think that the garden of our friend, Mr. James Allen, at Shepton Mallet, may best be likened to a laboratory for the fashioning of precious gems. Those of us who have the privilege of corresponding with him, and of growing his new flowers, can to some degree realise the work which has been done at Park House, and which, one would fain hope, may long be continued in Mr. Allen's new garden. Snowdrops alone do not comprise the objects of his work, and among other flowers the Wood Anemones are in hand. From the fine A. n. Robinsoniana has been produced the very beautiful A. n. Alleni. This seedling, when one has had it thoroughly tested, is a marked advance on its parent, or anything else we have in the same section. The flowers are larger, more perfect in form, and even finer in colour. The whole habit seems also more vigorous, and the longer it is grown the better is it liked. There are yet other seedlings to come from the same source, but it may be some time before anything yet to come will supersede the beautiful A. n. Alleni. *S. Arnott, Carsethorn, by Dumfries, N.B.*

EVAPORATED VEGETABLES.

THE factory of the British Preserving Company at Rayne stands on a plateau about 200 feet above the sea, on the edge of the London clay, in the county of Essex, upon a gravel bed 25 feet in thickness, overlying a bed of clean, sharp sand, bearing ample water of exceptionally good quality, though very hard. In the erection of the factory great attention was paid to the sanitary arrangements and the comfort of the workers, most of whom are young women. The main hall is about 80 by 30 ft., and at one end is the engine and boiler room, at the other the kitchen or copper room, with storeroom and the workpeoples' rooms beyond. On the north side runs an annexe, in which are various bags for receipt and storage of the raw material and for sundry subsidiary processes. Outside there is a forge, a tin shop, and a large shed for baskets, mats, sacks, &c., which take much room. The most scrupulous cleanliness must be observed. The concreted floor of the main hall is channelled, and laid so that the constant swillings of water pass readily away.

The main feature of the large hall (apart from the shafting and numerous machines connected to it by belting, which first catch the eye) is what is called the drying canal. This runs along one side of the building, and has the appearance of an exaggerated wooden counter. Its internal dimension is about 4 feet square, and throughout its length is laid a small tram line, along which run the wagons containing ten or twelve perforated zinc shelves for the prepared vegetables. Outside the canal runs a similar tram line by which the wagons, having passed through the canal, are returned to the end to be again filled and passed through. A hot blast is driven into the canal by a powerful fan, and rapidly takes up the moisture of the vegetables, so much so that at the further end an exhaust fan with a high number of revolutions is required to extract the moisture-laden air, and expel it through an upcast shaft.

The amount of moisture extracted from vegetables differs largely in various kinds, Onions being reduced to about one-tenth of their original weight, and other vegetables to a less extent. The time and the degree of heat required by each also largely differ, and in the knowledge of this lies much of the success of the process. When the vegetables leave the canal the slices are crisp as biscuit, and a slight re-absorption of atmospheric moisture must take place before they are ready for compressing and packing. For this purpose they are spread on a wooden floor, and here again experience is needful in order to seize the proper moment. It is claimed that all the natural and essential qualities of the vegetables are retained without any diminution by this process.

Having described the most important part first, we will now rapidly follow the process of preparation. Down the middle of the room are tables at which the girls stand, each with two baskets on the floor, one on either side. On the table or beneath it are the various small machines for peeling or slicing, most of them very ingenious. The idea of peeling Potatos in a lathe strikes most people as ludicrous, but it is true. Larger machines for washing Potatos, Carrots, Onions and other kinds by rotatory action, and slicing them, stand round the walls, while a notable Pea-shelling and sorting machine of large dimensions makes a sort of centre. Steam-heated plunging tanks occupy one corner, and large butts of cold water another. The machinery in the conserving room is of the newest description, but being commonly used in this country needs no description. It may be well to state here that the vegetables prepared at Rayne are absolutely free from chemicals, and have passed the Government analyst as perfectly pure.

The principal feature of successfully evaporating vegetables is to wholly extract the water without burning or drying up the fibres and tissues that are in them, otherwise the vegetables will not thoroughly re-hydrate again or re-assume almost their normal size, while no matter how properly and carefully they are cooked they will be harsh and flavourless, and lose their natural aroma and colour. When properly evaporated each vegetable should retain its own peculiar aroma, essential oil, strength, goodness, colour, and flavour.

Almost every kind of vegetable and herb is capable of being preserved by an evaporating process, and if care be taken to get rid of the moisture contained in them they will keep for an indefinite period in any climate, so long as they are kept covered in a tin box, so as to prevent their absorbing the moisture contained in the air.

Radishes, Lettuce, Watercress, and such like vegetables cannot be done successfully, because it is impossible by re-hydrating to get back the crispness, which is their leading characteristic.

The time required for the drying process is from two hours and a half to four hours, starting from a gradual heat up to 45° to 75° Celsius (= Fahr.), such heats varying according to the vegetable dealt with. It is inadvisable, as also almost impossible, to lay down a fixed rule as to temperature required, as the condition of the vegetable, whether a wet or dry season, its growth, and even the soil upon which grown, have to be taken into consideration.

The process of evaporation does not in any way alter the condition of the vegetable so treated either in making it fresher or staler. Fresh vegetables will come out from the process fresh, and stale vegetables cannot be altered, but will come out stale. The best time to put the vegetables through the process is when they are at their full growth and their nutritive qualities at the highest point. Vegetables grown upon sewage farms or on very highly manured market gardens are not the best for the factory, as in both cases they contain a much higher percentage of water than those grown upon less quickly forcing soil, and it is an open question as to whether they would have such good keeping qualities when grown on the former as on the latter. At the same time it is important to avoid using vegetables that are grown on poor soil, which consequently are a long time growing, and must be necessarily coarse and spongy, in the case of roots and such like, and stringy and tough in the case of Cabbage, &c.

By the evaporation process, all classes of vegetables as they come in season may be preserved and used for culinary purposes, irrespective of seasons, so that Carrots, Turnips, Parsnips, and Onions, these forming perhaps the most useful, may be obtained all the year round in their full nutritious condition and at reasonable prices. Under the old order of things during the months from April to September it is very difficult and expensive to obtain such from natural sources.

When needed for use, evaporated vegetables require soaking in water for from two to six hours, according to the sort. After soaking, they may be cooked in the same way as ordinary fresh vegetables of a similar nature. Vegetables required for soups need not be soaked so long as those for the vegetable dish. By adopting a sound and proper process of evaporation, and by taking great care for the cleanliness of all the surroundings, and quickness in dealing with the produce from the first commencement of the process, which is the peeling, to the last, which is the pressing and packing, the colour of each vegetable and its own natural aroma and qualities may be retained without the use of any colouring matter or chemicals.

For army, navy, and colonial use, where vegetables are scarce or impossible to obtain, evaporated vegetables form a splendid substitute for the original article, and beyond question hold their own far beyond any tinned substitute, both in flavour and quality, while they are certainly much cheaper, comparing solids with solids, and very much easier to handle. By hydraulic pressure, which in no way injures them or deteriorates from their value, it is possible to confine a large quantity of evaporated vegetables in a very small compass, which very materially lessens the cost of transport both by land and sea.

As an aid to agriculture, which is still the largest industry in the United Kingdom, the evaporation business will require a little time to firmly seat itself, but as to its ultimate success, an object lesson may be learnt from France, Germany, and America, the two former for vegetables and the latter for fruit. France was the originator of evaporated vegetables, which were first used prominently by them in the Crimean War in the feeding of their soldiers. Since the Franco-Prussian War, Germany has made very great strides in their manufacture, so that now in that country, and in France, factories for evaporating vegetables may be reckoned by the score.

Dried vegetables may be seen and bought in most of the grocers' shops on the Continent, as they have now become universally used by the householders of the great cities and towns. For cheapness, saving of time and trouble in peeling and preparing, for doing away with the nuisance of the peelings and garbage stored in or near the house, evaporated vegetables should be extensively used in London and all great centres of people.

The gold medal and diploma of honour were awarded to the Rayne vegetables at the Universal Food and Cookery Exhibition, held at the Imperial Institute in March last, where they were extensively used in the practical demonstrations. *Paper read by Mr. R. Grafton Salmond at the Horticultural Club.*

GOOD BROCCOLI.

OF late years, there have been some valuable additions to the early and late Broccolis, and few varieties have proved more useful than Model (see fig. 132), and Continuity (see fig. 133). In this country the Broccoli is a somewhat uncertain crop, as the plants are not capable of resisting our severe winters; yet much has been done in respect to obtaining a dwarfer plant, with a shorter leg or stem, and therefore less susceptible to injury by frost. Of course, much depends upon the cultivation afforded the plants, and upon the soil. In light soils they make more growth, and are more readily influenced by the weather; in heavy land, I have secured much better crops.

It is important that the plants be not permitted to remain crowded together in the seed-beds, or the time and strength so lost will affect them most injuriously. I know that it is very well to describe the best system of culture, but a different matter to carry it out, as many growers have to double-crop the land, with the result that one crop is not always cleared before the succeeding one should be put out; and in gardens where labour is insufficient, press of work may delay the planting. In such cases I would suggest that the plants be pricked-off, and much sturdier plants will be thus obtained than when drawn direct out of the seed-bed, and they will suffer much less in severe weather. Another point of great importance to the grower is that such a practice renders unnecessary any heeling-over in the late autumn to preserve the plants, and thus a check is avoided and better heads secured.

Needing Cauliflower or Broccoli all the year round, it is necessary for me to grow those kinds that may be relied upon, and I say that some do not always turn in at the times wished. For many years the best mid-winter variety was Snow's Winter White, catalogued to come in during December or January, and described as the best winter variety in cultivation. Doubtless the original stock answered to this description, but I am unable to get the true variety. As an earlier variety, no one will complain of lack of quality or fixity in Veitch's Self-protecting Autumn, a most valuable introduction, true to name, and a splendid Broccoli in succession to the Autumn Giant Cauliflower. I wish, by sowing later, we could get this variety in mid-winter, but find it impossible.

Of late years my best winter variety has been Sutton's Suberb Early White, which, if sown in April, or on our light soil, will turn in during February; and though not large, it is a most valuable vegetable. I am not in favour of large Broccoli at any season, and they are of poorer quality than the smaller, firm, compact heads, well covered with foliage. The last-named variety is not a large grower, having a very solid head; and I have lifted plants with their heads partially formed, and they have remained good for weeks. Another excellent type, and a good succession to the Superb Early White, is Veitch's Spring White. This is somewhat like the Early Penzance in build, and is an excellent variety for cutting in March; the heads being well protected by the leaves, and the plants are dwarf and hardy, turning-in before the spring varieties if sown in April and planted-out in June. There are others well worth naming, but I do not desire to give a long list; as most growers know, there is no lack of what we may term Spring Broccoli, and I find a few of the sulphur-coloured heads well worth room. I have, for instance, for many years grown the Sulphur, or Portsmouth, and find it valuable for its hardiness, and its colour in no way affects the quality. Another good form is the Penzance, but there are several varieties of it, for with me it varies much in quality, my best stock having come from a large grower who had only this variety for many years. Of course Broccoli stocks become mixed and deteriorate like other vegetables, and there is continual need for selection.

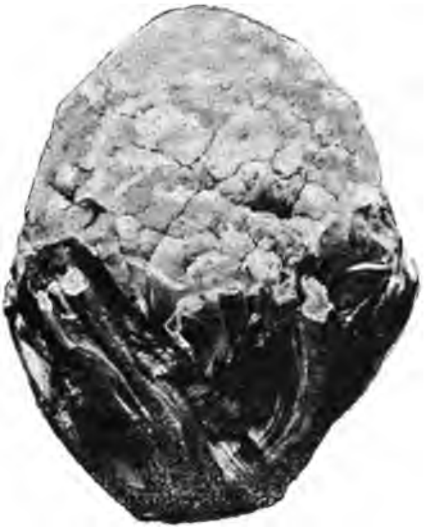

FIG. 132.—VEITCH'S MODEL BROCCOLI.
(*Photographed from life. Much reduced.*)

Veitch's Model (fig. 132) was a great gain on some of the older forms, as with a dwarfer habit the plants are more likely to escape frost. This variety we sow in quantity in May for cutting the following April and May, but this season there were few left for late May use. A still later variety is Sutton's Continuity (fig. 133), and it is not yet much known. It is a very fine type, and the head or flower, as will be seen in the illustration, has a great depth, and is entirely covered with foliage. The variety is a most valuable addition to the later kinds, and I hope to grow it in quantity another season.

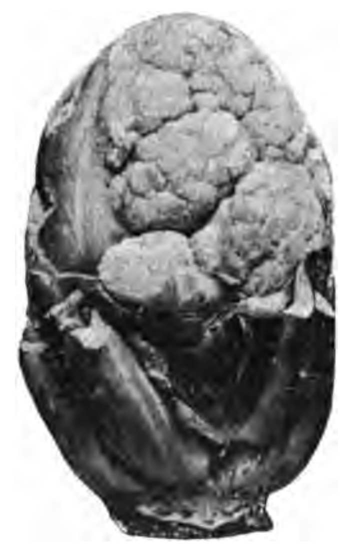

FIG. 133.—SUTTON'S CONTINUITY BROCCOLI.
(*Photographed from life. Much reduced.*)

Late Queen and June Monarch are also valuable late varieties, and very hardy. They are well known, and the last-named is a great favourite in the North, as it continues the supply when all others are over. *G. Wythes.*

AMERICAN NOTES.

PERSIMMONS.

THIS fruit is undoubtedly becoming more popular in America, though perhaps its increase in favour is not so rapid as might be wished. For the most part the Persimmon is still known as a wild fruit, with a somewhat dubious reputation. A taste for it among the coloured people of the South is almost proverbial, and white folks have seemed sometimes to feel as though this put it rather beneath their notice; still, there are many refined persons whose taste for fruits is above suspicion, and who do not scruple to relish openly their basket of ripe Persimmons. The native Persimmon is, in fact, a luscious fruit when at its prime, and it is a matter of great regret that more persons of good manners do not have the opportunity to cultivate its acquaintance. The supply of wild fruit is limited and uncertain, so that it has not found a firm footing in the market. Fruit-buyers seldom ask for it, and shippers seldom consign it to the city commission men. Attention has been called several times of late to this fruit, however, as a profitable fruit for cultivation, and in a few instances small orchards have been set. The Japanese Persimmon, or Kaki, is also becoming more common in America, and is somewhat frequently planted in the Southern States. It is occasionally seen in the markets, but not often enough to make any real impression. In a recent study of the varieties now propagated in this country, Professor Watts of Tennessee enumerates ten named sorts of American Persimmons, and seven of the Kaki.

THE VELVET BEAN.

Some time ago the Editor of the *Gardeners' Chronicle* wrote asking me about the Velvet-Bean in this country. I have just received a pamphlet from Mr. J. F. Duggar, detailing his experiments with the Velvet Bean in Alabama. This plant (which he calls Mucuna utilis), was found to be a useful species in nitrogen collecting and soil-improvement. When tried beside the Cowpea, one of the mainstays of southern agriculture, it gave practically equal results. When Sorghum followed Cowpeas in the rotation, there was an increase of 3216 lb. in the cured hay, as compared with a total of 3792 lb. of cured hay from plots unfertilised by the growth of Cowpeas. On plots where Sorghum followed the Velvet Beans, the increase was 3272 lb. of cured Sorghum-hay. Still more remarkable results were secured when Oats followed the Velvet Beans. The bines and foliage also make excellent hay. The plant does not seem to thrive except in the extreme southern States.

LANDSCAPE GARDENING BOOKS.

There seems to be quite a little competition in sight for the sale of books on landscape gardening. There are two new ones on the market, and more coming, they say. The two already published are by Professor S. T. Maynard, of the Massachusetts Agricultural College, and by Mr. Samuel Parsons, junr., ex-Superintendent of Parks for New York City. Both are small, handy volumes, of a popular nature, intended for the small purses of home planters. Professer Maynard calls his, *Landscape Gardening as applied to Home Decoration*; and Mr. Parsons chooses the title, *How to Plan the Home Grounds*. It will be seen that the field proposed by these two authors is nearly identical. The treatment is sufficiently diverse, however, to remedy any difficulty that might arise over duplication of subjects. The two books are as unlike as though one were stoichometry and the other philately. Professor Maynard's book abounds in practical advice. Practical advice is usually the most useless kind of stuff in a book, but in this case it does not seem so to me. The directions here given for doing this and that, and for caring for this or that plant, seem to be really useful and appropriate. This feature of the book is its strong point. Mr. Parsons' book is more readable and entertaining, and will appeal more to persons of another taste. Both books do credit to good publishers, and are very acceptable additions to our horticultural libraries. In this country, we have had several good books on landscape gardening in recent years; and there seems to be some justification for the belief that public and private taste is improving along these lines. These books are, doubtless, at once the sign and the cause of some of the improvement. *F. A. Waugh.*

CULTURAL MEMORANDA.

STATICE LATIFOLIA.

This species, known in the vernacular under the name Sea Lavender, is the prettiest of the hardy species of Statice. The plant produces numerous flower-stems, 1½ foot high, that are well above the foliage, and bear purplish-blue flowers. The colour of the flower is retained by them for several months after being cut from the plant, provided they have just become fully expanded at the time. The flowers, if intended to be preserved, should be hung in an airy room till quite dry. For intermixing with other flowers of like nature in winter-vases the flowers are invaluable. Afforded an open position, and a rich loamy soil, Statice latifolia thrives admirably. If the soil of the garden is not exactly suited to its requirements, it may be made suitable at a small cost of labour or materials. The plant is deserving of cultivation; for, apart from the usefulness of the flower-spikes in a dried state, it affords a pleasing contrast to other herbaceous perennials.

A fortnightly application of slightly-salted water in the summer favours growth. One ounce to 5 gallons of rain-water will suffice, or a small quantity may be added to farmyard manure-water. *H. T. M.*

IRELAND.

THE ROYAL HORTICULTURAL SOCIETY OF IRELAND ROSE SHOW.

The summer show of the above Society will be held in Merrion Square on Thursday, June 29, and promises to be a great success. Their Excellencies the Lord-Lieutenant and Countess Cadogan have accepted the invitation of the Council to visit the show. Of the many choice prizes offered for competition, the following are the chief ones:—For a stand of thirty-six Roses, Messrs. Dickson & Son, Newtownards, have given a Silver-plate, value £25; E. Johnson, Ltd. (Dublin), for a stand of Roses, seventy-two blooms, thirty-six varieties, open to nurserymen only, a Silver Cup, value £5; Messrs. Hartland, Cork, a Challenge Cup, value £6, for a stand of Begonias; Major Domvile, J.P., a Silver Cup, value £5, for a stand of herbaceous plants; a Silver Plate, value £10, for a stand of Carnations or Picotees, twenty-four bunches; and Mr. Watson, Clontarf, a Silver Cup, value £5, for a stand of Carnations, twelve bunches; Messrs. Kelway & Sons, Langport, Somersetshire, a Silver-gilt Medal, for a collection of cut flowers. There are forty-five competitive classes in all, and the Society give three money-prizes in each class. Intending exhibitors should remember that all entry-forms must be lodged with the Secretary (W. H. Hillyard, Esq.) by the morning of the 23rd inst.

Dublin Naturalist Field Club.

The members of the above society took their second excursion to Ireland's Eye on May 27, under the direction of H. K. G. Cuthbert, Esq., honorary treasurer. The excursion was attended by twenty-eight members and their friends, and they left Amiens Street by the 1.55 P.M. train for Howth; and on arrival at Howth they embarked in boats at the west pier, and reached the island in about half an hour, one of the boats being retained for dredging purposes. The majority of the members followed their inclinations, which were botanical.

Dublin Weather.

The summer weather we are enjoying will bring gladness to the hearts of our gardeners and farmers, after the heavy rainfall we had about the middle of May, which well saturated the ground. The gardens and pastures were, a fortnight ago, bare of verdure, but they are now covered with Nature's richest raiment.

The expectations of fruit cultivators are likely to be realised in good crops of most kinds of hardy fruits, and as a consequence the trade in baskets, &c., is very lively.

Flowering plants in the public parks are backward, and we must wait some time longer ere we see the usual floral display in beds and borders.

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Odontoglossum citrosmum.—The flowering season of this fragrant Orchid extends from the end of April to June. As each plant passes out of bloom it should be examined, and if needing fresh compost, this should be afforded, as root action will commence at once. This species thrives best when grown in baskets or well-perforated pans, either of which should be suspended. Each receptacle must be efficiently drained, and a small quantity of peat and sphagnum-moss may be used around the base. The plant will require a light and airy position, in a house where, ordinarily, an intermediate temperature is maintained, and though they require an abundance of water during the growing season, no fresh supply must be given until the compost has dried considerably.

O. grande and others of this section have little in common with the above species. Having rested since last season's growth was completed, each plant should now be given fresh rooting-compost; but before supplying them with new peat and freshly-picked sphagnum-moss, all of the old material should be carefully removed. Plants in pots may be placed in an intermediate house, where they will enjoy a moderate amount of light. O. Insleayi is liable to be injured during winter when the plants are resting if the compost be saturated too frequently. When affording water to these plants during the early stages of growth, it is well to prevent any from lodging on the leaves.

Trichosma suavis is rarely seen in good condition, because the plants are grown in greater heat than necessary. It is a cool-growing plant from the Kashya mountains, and of sufficient merit to be included in all collections. The partially-developed pseudo-bulbs are now emitting new roots, and if repotting or re-surfacing be required, it should be done. Fill the pots to within 1½ inch of the rim with drainage material, working in amongst the roots a compost of equal parts of peat, fibrous loam, and sphagnum-moss, with a dash of silver-sand. The plants may be placed with the Masdevallias, and water given them but sparingly until they are thoroughly re-established. They should be kept moderately dry during the winter months.

Ada aurantiaca.—This desirable Orchid thrives best in a position at the warm end of the cool Odontoglossum-house, and treated in most respects like those species. Having now flowered from the partially-developed growths, root-action will commence, and any attention the plants require should be given them without delay. The roots do not often become attached to the sides of the pot, and any plants, therefore, that require larger receptacles may be turned out like ordinary plants, and some of the old soil removed. In repotting the plants, use a quantity of crocks, but little compost. The more compost afforded, the greater must be the care exercised in the matter of affording water.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

The Late Vinery.—The Vines will now be fast coming into flower, and the varieties Lady Downes' Seedling and Alnwick Seedling, which are not free setters, should be specially treated so as to aid pollination, either by syringing the Vines once a day while they are in flower, or using a large camel-hair brush, or a few feathers charged with pollen obtained from flowers of Black Alicante or Black Hamburgh. The temperature of the vinery should be well kept up at this time, and atmospheric moisture lessened in amount somewhat, and the borders should be afforded water; but this matter should be attended to just prior to the flowering of the Vines. With Gros Colman and Black Alicante it is sufficient to shake the rods about noon in order to set the flower.

The Muscat Vinery.—The Vines, if started in February or at an earlier date, will now have reached the first stage of colouring, a time when they are apt to scald from sun-heat, or when exposed suddenly to bright sunshine. Care must be taken in removing lateral growth not to remove any foliage that affords overhead shade; later, when colouring is well advanced, more sunlight will be helpful in attaining that rich golden tint so generally admired in Muscats. Muscat Grapes, however, will perfect their colour under the shade of the foliage, without any special aid, when they are permitted to advance steadily, and to remain on the Vine till they are ripe. Exposure of the bunches need only be done to suit any special circumstances, and it may be said here that colour obtained in that manner does not endure, neither does the fruit keep, but it soon shrivels. Muscats generally possess leafage that is less robust than that of other Vines, and bunches on laterals at the usual distance apart obtain sufficient light. The ventilation if increased in volume at this stage will be of much assistance, though, unlike black Grapes, they do not benefit to the same extent from the sashes being opened at night. Six A.M. is not too early to begin to air this vinery if it be in a southerly aspect, or as soon as the earliest sun-ray touches it on other aspects, increasing the amount of air as the warmth increases. If the foliage or the berries are apt to scald in any vinery, a slight coat of shading should be applied to the roof-glass with a syringe, or a fish-net doubled should be drawn over it. In all bunches of Grapes except the latest Muscats it is easy to be seen at this date which of the berries are stoneless, and as these disfigure the bunches by their small size, they should be removed. The size and perfection of the berries will, of course, be governed by the condition of the Vines, of the border, and their treatment from the time of starting; but much may yet be done with healthy Vines in obtaining berries of the largest size. The supply of water should be increased if this is desired, accompanied by frequent dressings of artificial Vine-manure, or liquid-manure diluted in accordance with its strength. With a continuance of the present heat, the floors and other surfaces must be moistened often.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Winter Crops.—During the present month the bulk of the late autumn and winter crops of Brassicas will have to be planted. A beginning should be made with those that turn in early, planting these by themselves so that whole quarters may be cleared at one time of the remains of the crops, and put to other uses. The mid-winter and late crops should be similarly treated. Taking Cauliflowers first, there are those of the Dwarf Erfurt type, following on with Walcheren, and others, and finally setting out Autumn Giant. Next come the early Broccolis, viz., Snow's Winter White, Self-protecting Spring White, and the many mid-season varieties, finishing with Model, Ledsham, and Late Queen.

Cabbage.—The present month sow a small quantity of seed of the small-hearting Cabbages for planting on any vacant plots, viz., Little Pixie, London Coleworts, Ellam's Early. The small-growing varieties may be planted at from 12 to 16 inches apart, on land that has been lightly forked over, or merely hoed deeply, drawing drills as for Peas, and planting therein.

Celery.—In dull weather, put Celery, when large enough, into trenches, and afford it plenty of water. If the trenches are dry at the time of planting, let water be afforded, and also afford water to the nurse-beds before lifting the plants. If plenty of manure was put on the trenches, it will suffice to apply only clean water. See that the plants do not get drawn before they are put into the trenches. During the month the successional batches should be planted from the nurse-beds.

Broad Beans.—The earliest plants being now in bloom and pod, should be topped, thus the black-fly that usually infests them will be get rid of, if the tops are put into a water-can, and scalded, and early podding induced. Keep the hoe at work among growing crops of Beans.

Tripoli Onions.—If the bulbs are going to seed, remove the flower-spikes forthwith, and slightly depress the tops. If very large bulbs are required, afford 1 foot space between the bulbs, and afford the beds a good dressing of guano or other suitable manure, and a copious application of water, being careful not to allow any manure to dry on the tops, or much harm may be occasioned. Remove bulbs which show signs of decay, removing them right away. Soot forms a good dressing for Onions, and may be used three or four times in the season. Keep the hoe in constant use.

Vegetable-Marrows. — Those which have been forwarded under glass should not lack water at the roots, nor be allowed to get crowded with weak, useless growths, nor the fruits to remain on the plants after they have become fit for table. The first lot of fruit sometimes turns yellow and drops off, more especially if the plants possess great vigour, the result of a very rich soil. A sandy, loamy soil, with not much manure, prevents this to a great extent; and later, when the roots get down to the manure of the hot-bed, heavy crops of fruit may generally be expected.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Richardia (*Calla*) *africana.*—Where the practice of planting-out Richardias is adopted, the required preparation of the land should now be made. Trenches about 1 foot in width and half-a-spit deep should be thrown out, and a layer of rich manure dug into and incorporated with the soil in the bottom of the trenches. The plants should be divided if a potful contains more than one, and be planted about one foot apart along the middle of the trenches. The balls should be made as small as possible, in order that they may come into pots of the same size as those they were taken from. It is a good practice to remove all of the small suckers before planting the roots, and setting these out in land apart if an increase of plants is needed. Another, and a very satisfactory method, is to lay the plants on their sides on the ground in the open air during the summer, and entirely withhold water from the soil. The foliage then dies down, and the plants remain dormant till about the end of the month of August, when signs of renewal of growth will appear. The plants should then be turned out of their pots, the old soil shaken from the roots, and these potted singly in a compost consisting of three parts loam and one part rotten hotbed manure; the small tubers being removed, and placed to the number of four in a 6-inch pot if stock is required. The plants should be firmly potted, ample space being left for holding water; stand them in common frames, and keep close for a week or ten days.

Bouvardias.—The older plants may be transferred to cold pits or frames at this season, gradually increasing the amount of air afforded, and after a week let full exposure take place in the daytime during fine weather. A syringing in the morning and evening will keep down red-spider, which is otherwise apt to be troublesome. Young plants raised in the early spring-time should be cultivated in an intermediate temperature, affording them a shift into larger pots whenever this is necessary. Pots of 5 or 6 inches in diameter will be sufficiently large in which to flower these young plants.

Herbaceous Calceolarias.—A pinch of seed may be sown now. To raise Calceolarias with success, let a few 4½-inch pots be filled with finely-sifted loam three parts, leaf-soil one part, and some silver-sand, having put in an inch of finely-broken crocks; after making the surface even, saturate the soil by immersing the pots almost to the rim in water. After allowing the water to drain away, sow the seeds evenly and thinly, but do not cover them with soil; a sprinkling of sand, however, is allowable. A sheet of glass or paper should be laid over the pots, which should be placed near the glass in a frame or hand-light on the north side of a wall, or some other coolish and moist place, where the sun will not reach them. Care is needed in affording water, and until the seedlings have taken a firm hold of the earth it is prudent to dip the pots to the rim in water.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Cannas.—Twenty years ago Cannas were grown chiefly as subtropical plants, to be admired for their fine foliage; but, thanks to M. Crozy and other French hybridists, we have now both fine foliage and showy flowers combined, the habit, too, being also rendered sturdier and dwarfer. Not only will Cannas grow in full sunshine, but they are successfully grown in partial shade. They are easy to cultivate providing the soil is light and rich; and when throwing up the flower-spikes, manure-water is liberally afforded. Although they form neat beds of themselves, they are more effective when mixed with Tobacco and Castor-oil plants, at a distance of 1 yard apart, with a ground-work of Melianthus major, or Centaurea gymnocarpa; and where the dark bronze-foliaged varieties are planted, Gazania splendens, or the dwarf Evening Primrose (Œnothera macrocarpa), make a pleasing contrast.

Asters.—The German and French Asters alike form fine masses of colour in borders or in beds. At Westonbirt we plant them in beds of 4 feet wide in the reserve-garden, the beds being dressed with rich, fresh loam, and after digging, making the soil firm. The plants under this kind of treatment grow sturdily, and an occasional application of weak liquid-manure is afforded till flowering-time. When planting Asters, let each be lifted so as not to break the fibrous-roots, and plant at a distance of 15 inches apart. The Pæony-flowered varieties are very noble-looking, and the Victoria strain, with double and imbricated flowers, form pyramids of blooms. The flowers of the Chrysanthemum-flowered Comet Aster resemble a Japanese Chrysanthemum, the petals long, and recurving from the centre to the outer petals. The shape is semi-globular. This variety requires a little more root-feeding than most varieties, and they are taller in growth, while the dwarf Chrysanthemum-flowered Asters bloom much later, and look well when used as edgings to beds of other species of plants.

Sweet Peas.—The latest sowing may now be made. The plants from early sowings, when they have reached a height of 4 inches, should have sticks placed to them, but leaving the lines of sticks open at the top. Afford occasionally mild soot-water; it gives strength to the growth, and increases floriferousness.

Roses.—Now is the time to remove all weakly growths from Tea and Hybrid Perpetual varieties. Briars that were budded last year as standards should not be allowed to flower, but be pinched back to three or four buds, which soon starting to grow, will form finer heads this season. The shoots of Briars planted during the past winter should be thinned to two or three, and these as near together as possible, and according to the height of the stem required. Where Roses are subject to mildew, the parasite may be prevented and removed by using anti-blight mildew powder, distributed by means of the Malbee bellows.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

Grape-vines.—The present is a suitable time for planting varieties of the Grape-vine in south and other warm aspects against walls. The plants should have been prepared for the purpose last year, being by preference strong cut-backs, grown in pots, and they should have made a little new growth. Assuming that stations have been formed for their reception, let the plants be turned out of the pots, shake a portion of the soil from the roots, liberating some of these, and lay the roots out horizontally, and radiating round the stem. Then work the finer particles of soil about these, fill the hole, and tread it firmly all over, applying a mulch of partially-rotten manure. The common Sweetwater and its variety, the Parsley-leaved, are desirable for out-of-door fruiting. When the bunches and berries are duly thinned, and other necessary attention afforded, these rarely fail to ripen perfectly in the southern counties in ordinary summers.

Strawberries.—The remarkable increase of warmth during the past few days will greatly hasten the ripening of outdoor Strawberries, and by the time this appears some of the earliest fruits will be ripe. In most gardens, the fruits have to be protected by fish-netting laid over the beds or lines as soon as the fruits commence to colour. Where Strawberries are grown near to a wall, short wooden stakes may be driven into the soil along the front, with about 4 feet out of the ground, and at a distance of about 8 or 10 feet apart. On the top of these a thin batten may be nailed lengthwise of the border, and the netting be suspended from the top of the wall and over this trellis to the front of the border, pegging it down to the ground, or to boards set on edge, which is better. Where large quarters are covered with netting, a framework should be erected high enough to carry it to allow of a person to pass easily under it when gathering the fruits. Mice sometimes nibble the fruits, or bite through the stalks and collect the fruit into heaps; and when this is the case, numerous baited traps should be set for them forthwith.

Peach and Nectarine Trees. — The final disbudding should be finished soon, all gross shoots pinched back to a basal lateral, and blistered leaves removed and burnt. Then comes the thinning of the fruit, which, I fear, in many cases will not be needed—at least, not to any great extent. At Dropmore, most of the trees carry more fruits than should remain, and as a beginning all clusters have been reduced to one fruit each, and all badly-placed, undersized ones removed. The early-ripening varieties, Waterloo, Alexander, and Amsden June, have set their fruit thickly this season, and these have already been thinned. If a heavy application of water be made to the border, the size of these early fruits will be increased, for notwithstanding the many showers that fell last month, the borders that skirt the garden-walls still require much moisture. If not already mulched, the border for a width of 4 feet measured from the wall should be covered with a 2-inch layer of half-rotten stable-manure. Water may be applied before and after this is put on the border. The trees should be syringed with clean water daily at 6 or 7 A.M.

THE APIARY.

By Expert.

Hiving Swarms. — Hiving swarms is a very simple matter, unless the bees happen to cluster in awkward places. When this occurs, the bee-keeper must exercise his judgment in adapting his procedure to the circumstances. Usually, however, there is no need for the troublesome precautions sometimes recommended. With a frame hive, ready for introducing the swarms into, it needs but to get the swarm into a skep by holding it underneath and shaking the bees from the bough on which they are clustered into it, carry them to the frame-hive and throw the swarm on to the platform, or by some similar means of running bees in, according to the form of frame-hive used. If they settle too low down to allow of the skep being held beneath, spread a cloth under the swarm, and on it fix the skep with the edge raised up, shake the bees on to the cloth, and they will soon run in. The only precaution we advise, is that beginners defer introducing swarms to frame-hives till after sundown. It is advantageous to feed all newly-hived swarms with thin syrup for a day or two, and to continue it whenever the weather happens to be wet or cold. Second swarms require particular attention by way of keeping them warm and cosy. They must not be allowed to occupy more than four or five frames, to be increased to six or seven before the end of August, and when this number is fully worked out, the bees will winter on them nicely. It also greatly facilitates comb-building — when the bees are not very numerous—if the entrances are kept narrow, and a board is firmly weighted down over the quilts, provision being made for feeding regularly. Where comb-foundation is given in full sheets to swarms, fix it very firmly on the top bars, or it may break down when subject to the great heat of a newly-hived swarm. It is safer to alternate the foundation with frames of ready-built combs, and at the same time allow a little ventilation at the top for a day or so after hiving where full sheets of foundation are used.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	June 10—	Royal Botanic Society, Meeting.
TUESDAY,	June 13	Royal Horticultural Society's Committees. National Rose Society, Committee Meeting. Royal Horticultural Society of Ireland, Meeting. Cambridge Horticultural Society, Exhibition.
WEDNESDAY,	June 14	Grand Yorkshire Exhibition and Gala at York (3 days). Royal Cornwall Agricultural Show at Launceston (2 days).
THURSDAY,	June 15—	Linnean Society, Meeting.
FRIDAY,	June 16—	Royal Botanic Society, Lecture.

SALES.

WEDNESDAY,	June 14	1000 Begonias, Greenhouse Plants, Dahlias, Japanese Lilies, &c., at Protheroe & Morris' Rooms.
FRIDAY,	June 16	Imported and Established Orchids, at Protheroe & Morris' Rooms.

Remarks.—The weather during the week has been warm and dry.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—60°·6.

Actual Temperatures:—

London.—*June* 7 (12 P.M.): Max. 80°; Min. 54°.

Provinces.—*June* 7 (6 P.M.): Max. 69°, South Counties; Min. 49°, Shetland.

Fine; hot; cooler; no rain.

Paris International Exhibition.

We have received through the courtesy of the Director of the Royal Gardens, Kew, a series of documents relating to the Horticultural Department of the Great Exhibition in Paris in 1900, and containing the general arrangements for the permanent and temporary exhibitions. The documents in question occupy some 136 pages, from which we can only condense a few leading particulars. We may say, however, that the schedules are framed with that clearness, accuracy of statement, and orderly arrangement, which are characteristic of French official papers.

The permanent exhibits comprise instruments, machines, structures, tools, garden-decorations, plans, books, greenhouses, fruit and other trees permanently planted out, &c. Applications for space may be made up to June 15, 1899.

Fruit-trees and ornamental trees intended for permanent exhibition should be planted in the course of 1899, or at latest before March 15, 1900.

Temporary exhibitions will be held on the following dates in 1900:—April 17, May 8, May 22, June 12, June 26, July 17, August 7, August 21, September 11, September 25, October 9, and October 23.

At these exhibitions collections from amateurs, nurserymen, and public bodies will be received according to the terms of the schedule for each particular date.

Among the regulations we find a distinction drawn between "lots" and "collections." The lots may contain numerous specimens of the same species or variety; but in "collections" only one specimen of the same species or variety can be shown.

Foreign exhibitors desirous of taking part in these temporary exhibitions, should make application through their Commissioner at least six weeks before the allotted date, and they will receive notice at least three weeks previously of their admission to the Exhibition.

It is obvious that such a regulation, if strictly enforced, would shut out many important exhibits. It will not be possible in all cases to say six weeks, or even three weeks beforehand, that a particular plant will be fit for exhibition. To meet such cases, there are various "*concours imprévus*" on each occasion, and these unforeseen contingencies or competitions may, and very likely will, prove the most important elements of the temporary exhibitions.

Turning to details, we find that Class 43 is intended to comprise garden structures, tools, implements, herbaria, books, &c. The temporary exhibits in this class comprise pumps on June 12; lawn-mowers on August 7; spraying apparatus on August 21, and heating-apparatus on September 25.

Class 44 is devoted to kitchen-garden plants. At each of the meetings above enumerated, exhibitions of vegetables according to the season will be shown.

Class 45 is devoted to fruit-trees and fruits. The permanent exhibition consists of trees and shrubs grown out-of-doors.

Temporary exhibitions will be held on the dates already specified, from April 17 to October 23, both inclusive.

Class 46 includes trees, shrubs, ornamental plants, and flowers. The permanent exhibition will consist of ornamental and of forest trees and shrubs, including Roses. The temporary exhibits are devoted to plants and flowers of various kinds, according to the season, on each of the allotted dates, competitions for new plants being held on each of the dates.

Class 47 is concerned exclusively with stove plants. In this division, there will be no permanent exhibition; but at the various temporary exhibitions, new plants, plants according to season, and plants remarkable for good cultivation will be represented.

Class 48 takes cognisance of seeds and seedling plants. The permanent collections will consist of seeds of various kinds, and of nursery stock and lawns. Temporary exhibitions will be held on April 17, May 22, and October 9.

We trust that as the facilities offered by our French friends are great, our nurserymen will cordially respond to the appeal made to them. Of one thing we may be sure, that if on certain points of detail we are surpassed by our continental rivals, and if we have something to learn from them, yet British horticulture in the main will be well able to hold its own.

Points about the Temple Show.

When writing or speaking about what there was, and what there was not exhibited at the Temple Show last week, it is worth remark that not one group of Codiæums (Crotons) was there. This is the more remarkable, because there is scarcely a garden in the country that has a hot-house, where some of these plants may not be seen. A collection of the best varieties to date might have been anticipated, therefore, at the Temple Show, especially as there are season after season very large exhibits of Caladiums, equally beautiful plants, but more tender and less suitable for the inevitable present-day furnishing business than are Crotons. Indeed, apart from the Caladiums, indoor foliage-plants generally are not given a conspicuous position at these shows. Messrs. Wills & Segar, Mr. Iceton, Messrs. Fisher, Son & Sibray, and one or two other exhibitors, had groups in which were specimens of several species of ornamental foliage-plants, most of them small, but in none of them was it attempted to display a representative collection of one species.

To change the general effect to be seen at the Temple Show from year to year, as seems so desirable, is not an easy matter. The simplest method would be to change the date of the exhibition. By so doing a different lot of plants altogether could be got into bloom; but the usual date is, we expect, not capable of alteration, and is necessary to the degree of success the event has attained.

Another means would be to compile a schedule each year, purposely omitting certain plants that formed an important feature at the preceding show, and thus providing space for new exhibits. But this could only be done to a limited extent. Who, for instance, would think of excluding from a Temple Show, even for one year, the displays of Orchids, Roses, or Begonias? Yet it is just such exhibits as these that make succeeding shows in a measure repetitions of former ones. In another column a correspondent draws attention to the fact that Pelargoniums were scarcely represented at the recent show, but we should imagine that had space been asked for an exhibit of these, it would have been provided by some means or other, and that the omission is on the part of the exhibitor.

The authorities would not give space for duplicate exhibits of a plant to the exclusion of other important species not represented. It is sometimes argued that the general effect of the show might be altered if the exhibitors would but arrange their collections in a different style. It should be remembered that the space given for most exhibits is quite insufficient for this, even were exhibitors inclined to take additional trouble to make novel arrangements.

The only alteration worth mention that could be done by mere arrangement must be done by the Society itself, and by giving to each exhibitor a site as widely different as possible to that he had in the previous

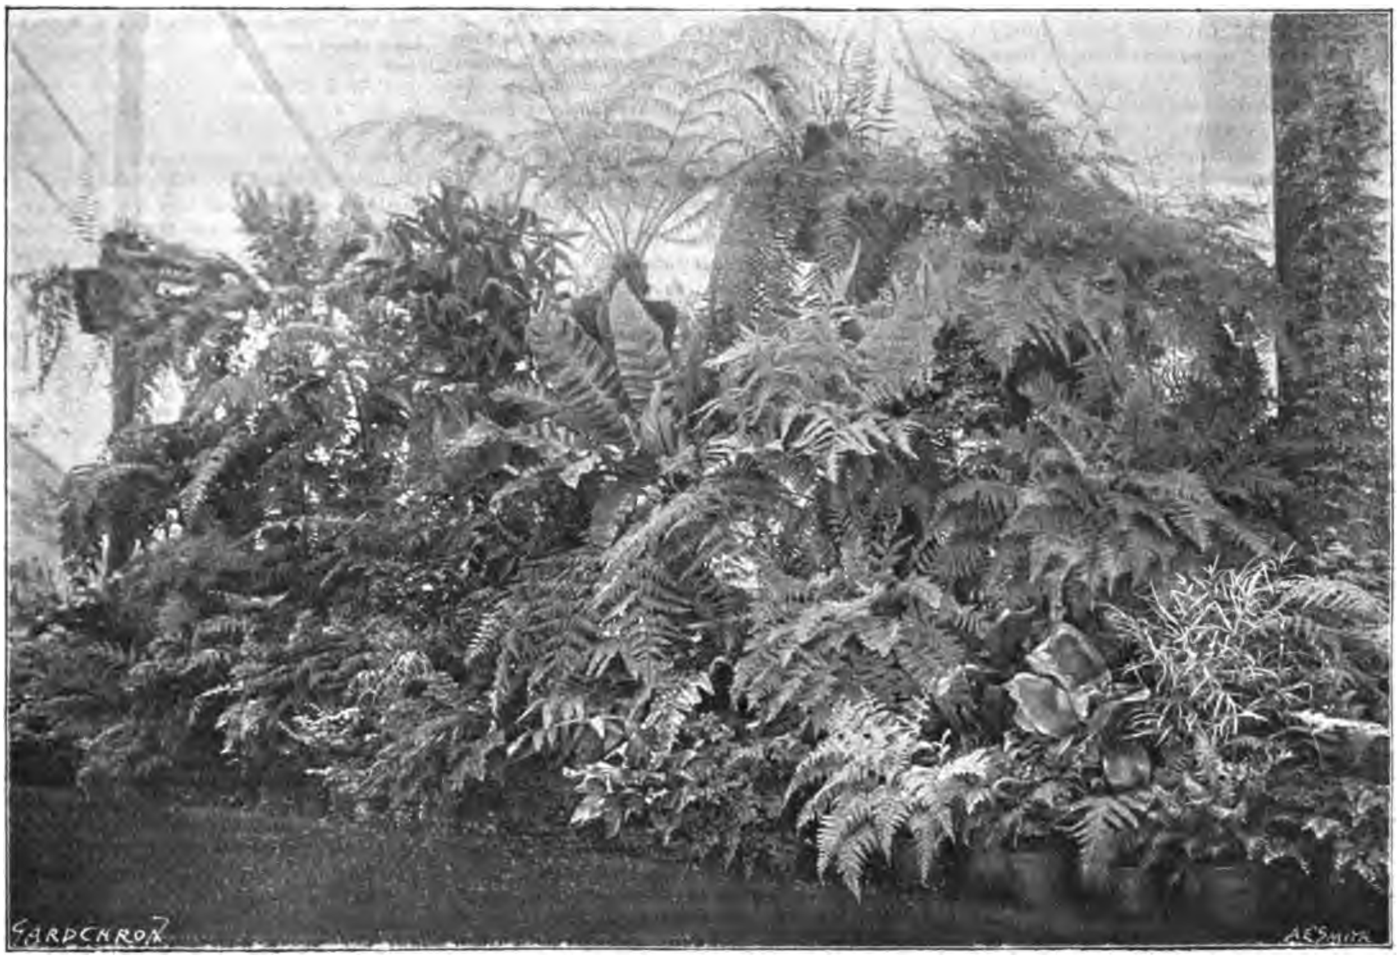

FIG. 135.—GROUP OF FERNS.
Exhibited by Messrs. J. Hill & Son, at the Temple Show.

year. Instead of this, we know before entering the tents where the Orchids will be, and where the Roses, Begonias, Cannas, and many other plants are likely to be found. Some of the photographs of groups which were taken for us last year, but not used, might well have been utilised this year, so slight was the difference in the plants, and in their method of arrangement. There might be much more variety obtained in this direction.

In regard to the financial aspect of the show, the council, since it abandoned the strict measures taken four or five years ago, when the tickets of fellows and exhibitors were punched upon entering, has not given the least opportunity for complaint on this score. But several cases that came to our knowledge at the recent show seem to indicate that some of the Fellows are too exacting in their demands on the Society. A Fellow's transferable ticket may be passed to a friend or a friend's friend perhaps, but it was surely not intended that such a ticket should admit a person to the grounds before the previous one that used the same ticket has left them. That this was done in some instances is matter of common knowledge, and is highly discreditable.

From the official catalogue, it appears there were about ninety exhibitors on the last occasion, but many of these showed several collections of plants. H.R.H. the PRINCE OF WALES visited the exhibition on the second day. In our present issue we give several additional illustrations which neither time nor space permitted us to give last week. No further explanation of them beyond reference to our report last week is necessary.

Garden Products by Rail. NATURALLY this subject is at present exciting much interest among consumers living in towns. To Londoners, especially, the system inaugurated by the Great Eastern Railway Company in 1895 is of much value. Considerable success has attended the action of this company, as the undermentioned figures show. Packages conveyed in December, 1895, 1,378 (one month); in the following year ending December, 60,034; in 1897, 112,104; 1898 showed 135,860. The company forwards from every station on their system to London, and stations in the eastern suburbs, at a reduced charge of 4*d.* for 20 lb., one penny additional for every 5 lb. or part thereof up to 60 lb., including delivery within the usual limits (about a three-mile radius from Charing Cross), and special arrangements have been made with Messrs. CARTER, PATERSON & Co. for delivery in suburban districts beyond these limits. These rates will only apply subject to the following conditions: produce to be packed in boxes on sale at the different stations, or similar ones; boxes to be secured only by nails; the produce to be conveyed at owner's risk, and carriage prepaid—prepayment by parcel-stamps, to be had at the stations. No box to be of a greater weight than 60 lb. A pamphlet, to be had from the Company's agents, affords a long list of farmers and others who are prepared to send produce by passenger-train, and this will be found of great value to intending customers.

The G. N. Railway Company forward small parcels from about 170 stations on their system to London and other cities at the following educed charges, irrespective of distance: up to 20 lb. (inclusive) 6*d.* per package; over 20 lb., up to and including 30 lb., 8*d.*; 30 to 40 lb., 10*d.*; 40 to 50 lb., 1*s.*; 50 to 60 lb., 1*s.* 2*d.* These rates apply to every description of package that will admit of other packages being placed upon it. All other particulars, including a long list of producers, may be had from the Company's agents and stations.

The L. & N.-W. Company inform us that their arrangement for this year's carriage and delivery of small parcels of garden, farm-produce, &c., are practically the same as last year, and that the minimum charge has been reduced from 6*d.* to 4*d.* per consignment. The "owner's" risk scale of rates, and directory of producers willing to supply produce, &c., may be obtained from the Company's agents, and will be found of much use.

The Midland Ry. Company's Superintendent will also supply information on this matter. The railway officials state that at present they do not contemplate the making of new arrangements respecting the carriage of garden and farm-produce; but the agents of the Company will furnish every kind of information necessary respecting produce carried by passenger-train.

It appears to us that the various railway companies are warming to the work before them; it certainly seems to indicate the betterment of dividends, and the increased accommodation of consumers resident in cities and towns.

BIRTHDAY HONOURS.—In commemoration of the QUEEN'S birthday, Dr. BURDON SANDERSON, the Regius Professor of Medicine in Oxford, known in the botanical world for his researches on the electrical phenomena observable in plants, has been made a baronet. Prof. MICHAEL FOSTER, who needs no introduction to our readers, is made a K.C.B.; and Mr. JAMES SYKES GAMBLE, the author of the *Manual of Indian Timbers*, and the author of the excellent monograph of the *Bamboos of British India*, has been selected as a Companion of the Order of the Indian Empire. There are so many "orders" nowadays that it seems a pity that some of them are not consolidated into an Order of Merit, with appropriate departments. As things are at present, it is, to say the least, incongruous to give the same "honour" to a city magnate, a political opportunist, or a man of many acres and much cash, as to a member of the services, a judge, or a distinguished man of science.

THE BRITISH ASSOCIATION AT DOVER.—In connection with the forthcoming visit of the British Association to Dover, for their annual Congress, the hospitality and entertainment committees have, in connection with the officials of the Association, arranged a very comprehensive and diversified programme. The gathering will commence on Wednesday, September 13, when the President, Sir MICHAEL FOSTER, K.C.B., will deliver his address. On Thursday, the members will be invited by the General commanding the district to a garden-party at Dover Castle; and in the evening, the Mayor will entertain the Association at a banquet. On Friday, there will be a smoking concert in honour of the President at the Town Hall. On Saturday, the French Society of Science will visit Dover, and there will be a combined excursion to Canterbury; and on Sunday, there will be special services, military bands will play in the Connaught Park, Dover, and there will be organ recitals at Canterbury Cathedral and Dover College Chapel. For Monday, a garden party in the College grounds has been arranged, and a military tattoo by the bands of Dover garrison in the evening on the sea-front. On Tuesday, there will be an afternoon party to the Warren, the picturesque undercliff between Dover and Folkestone, locally known as Little Switzerland; and in the evening the Mayor will entertain the members at a *conversazione.* On Wednesday, there will be an excursion to Calais, and a ball at the Dover Town Hall; on Thursday, the Association will return the visit of the French Society at Boulogne; and for the five next days, until September 21, the programme includes excursions to Amiens, Antwerp, Brussels, Ghent, and Ostend. The botanical section will be presided over by Sir GEORGE KING, lately Director of the Royal Botanic Garden, Calcutta.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees of this Society will be held on Tuesday, June 13, in the Drill Hall, James Street, Westminster. At 3 o'clock a lecture on "Rock Gardens, Ponds, and Rivulets in Gardens," will be given by Mr. F. W. MEYER.

LINNEAN SOCIETY.—At the evening meeting, which will be held on Thursday, June 15, 1899, at 8 P.M., the following papers will be read:—1. "Contributions to the Natural History of Lake Urmi and its neighbourhood," by Mr. R. T. GUNTHER, M.A.; 2. "A systematic Revision of the genus Najas," by Mr. A. B. RENDLE, M.A., D.Sc., F.L.S.; 3. "On the Anatomy and systematic position of some recent additions to the British Museum collection of Slugs," by Mr. WALTER E. COLLINGE, F.Z.S.; 4. "The Edwardsia stage of Lebrunia, and the formation of the Œsophagus and Gastro-cœlomic Cavity," by Mr. J. E. DUERDEN, A.R.C., Sc.

"MY ROSES, AND HOW I GREW THEM."—By Helen Milman (Mrs. CALDWELL CROFTON), published by JOHN LANE, The Bodley Head, London and New York. At first sight this book seems small, both in size and in quality. It chronicles the horticultural adventures of an amateur, but as these are evidently genuine, and were on the whole successful, the enthusiasm with which they are narrated will awake an answering glow in other non-professional gardeners. Everyone loves Roses, and there seems to be an inexhaustible demand for books on the subject, although the name of these is already legion. The one before us is a simple record of an amateur's work, detailed for the benefit of other novices, and may therefore help and encourage them better than a more ambitious book could do.

"AN ENCYCLOPÆDIA OF GARDENING."—This is a "dictionary of cultivated plants, and an epitome of the culture of all the kinds generally grown in gardens in this country." It is from the practised pen of Mr. T. W. SANDERS, and it is the third edition which now lies before us. Therefore no more need be said to prove it a trustworthy and practical book, excellent for reference as containing much information in a handy form. (Publishers, W. H. and L. COLLINGRIDGE, Aldersgate Street.)

"THE BOYS' OWN PAPER."—In the June part of this popular magazine we note a good article by Mr. W. WATSON, entitled "A Chat about Lilies." To us the dialogue form in which it is written is a little irritating, and suggestive of *Evenings at Home*, and other highly instructive old friends; however, it gives scope for plenty of useful information. As illustration, there is a large coloured plate, by Mr. JOHN ALLEN, and a diagram of it showing thirty-two species of Lilies, so beautiful and gorgeous as to rouse emulation in the heart of every boy-gardener who sees it.

SUCCULENTS.—We understand that the fine collection formed by Mr. COOPER, of Reigate, is for disposal. Mr. COOPER is well remembered as an energetic and judicious collector in South Africa, and contributed not a little to the once famous garden of the late WILSON SAUNDERS.

COMING ROSE SHOWS.—The enclosed fixtures kindly sent us by Mr. E. MAWLEY, are in addition to those published in our issues for April 1, p. 202, and May 6, p. 282:—June 27 (Tuesday), Southampton; July 5 (Wednesday), Hitchin, Redhill (Reigate); 8 (Saturday), Manchester; 11 (Tuesday), Reading; 13 (Thursday), Norwich and Woodbridge; 14 (Friday), Ulverston; 15 (Saturday), New Brighton.

KEW.—"Cyclists will be glad to learn that, by order of the First Commissioner of Works, a large cycle-house for the storage of machines is to be erected at Kew Gardens for the convenience of visitors cycling to that place. There has been a similar house at Hampton Court Palace Gardens for the past two years," says the *Daily News*, "and it is greatly appreciated."

HAMPTON COURT GARDENS.—Those of our readers who may never have seen giant plants of the old Wistaria chinensis in bloom, could not do better than pay an immediate visit to the popular rendezvous of Hampton Court. In numerous localities does this sweetly pretty Chinese climbing plant grow and flower abundantly, but we have never seen such displays as are produced each year in the grounds of this once royal residence. Some of the plants are such veterans that in size and age they are little less remarkable than the famous Vine, but of which a great deal more is heard. Their branches stretch quite as far, and the bark of the principal ones is most interesting. But there is not only one plant, or a dozen. They appear to have been planted in almost every convenient situation, with the result that a visitor during the first fortnight in June, when the plants are literally smothered with pendent racemes of sweetly-scented, peculiarly-tinted blooms, remembers them afterwards as the pleasantest feature of the place; and they overflow even into the village, for one of the hotels there boasts a fine specimen. It is a plant that is worth cultivation in any locality where it can be made to flourish, and in a good soil, when the plant has become established, it is a very quick grower. Sometimes, however, there is considerable delay before much growth is made, and in certain midland counties we have tried to cultivate the species with indifferent success. A few days since, when we went to Hampton, more particularly to again see the Wistarias, the gardeners were busy putting out the summer bedding plants, which, so far as could be seen, were of the usual miscellaneous species. But a remark is well deserved by two large beds filled with varieties of Ranunculus asiaticus. These were almost all that remained of the autumn-planted bulbs, and the gratifying effect of so many beautiful colours was enhanced by the perfect appearance of the beds. Every plant has flowered grandly, and they should be sufficient to persuade gardeners to take a little more care with the Ranunculus, that at one time claimed as much attention from the cultivator as did Tulips. Other floral displays at the moment are those of the Rhododendrons and hardy Azaleas, the former being particularly good.

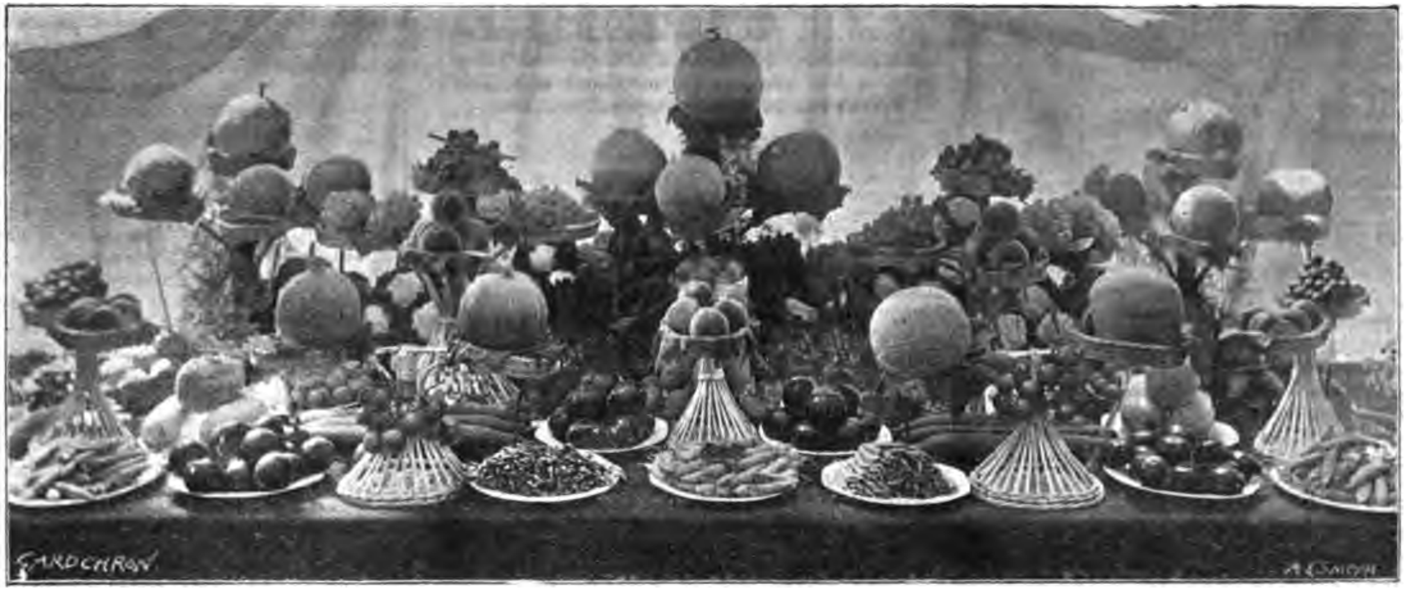

FIG. 136.—AN EXHIBIT OF FRUIT.

(Exhibited at the Temple Show by Mr. W. Bastin, gardener to H. Henderson, Esq., Buscot Park, Berkshire.)

MANURING FRUIT-TREES IN HOLSTEIN.—A method of fertilising fruit-trees in vogue in Holstein is suggestive, and not unworthy of a trial. The trees, it is said, receive no cultivation, and the fruit is large, sound, and produced in abundance. Every two years a few holes are dug in the ground about 4 or 5 feet from the trunk of the tree, and about 1 foot deep, closer and shallower in the case of young trees. These holes are filled with liquid-manure about four times during the winter months, and for young trees this is diluted with water. If there is more liquid-manure than is wanted, it is distributed over the surface of the orchard, using an old street sprinkling-waggon for the purpose. There is no reason why manure-water should not be used once or twice after it is seen what the crop is likely to be; of course, not affording any at that season to trees not bearing a crop, or which are carrying only a few fruits, as to dose them would be to encourage, probably, an unnecessary growth of shoots. But in this matter, the cultivator must be guided by the condition of the trees, and of the soil.

JUBILEE CELEBRATIONS AT GHENT. — An exhibition and certain fêtes are to be held in Ghent next July in commemoration of the fiftieth anniversary of the foundation of L'École d'Horticulture de l'État. The following is, in brief, the programme proposed:—

SATURDAY, JULY 8.—Reception of the members of the jury, the work of judging, and a lunch to the jury. In the afternoon, at 3 o'clock, a meeting in the Academic Hall of the Ghent University; appointment of a committee to consider the advancement of horticultural education; institution of the committee, and formation of sections. Lecture and discussion of the reports of the sections. In the evening a reception at the Hôtel de Ville by the burgomaster and aldermen.

SUNDAY, JULY 9.—In the morning a visit to the grounds of M. VAN HOUTTE, and the University Botanic Gardens, the former locations of the École d'horticulture. Visit to the winter garden of Comte de KERCHOVE DE DENTERGHEM, and to various horticultural establishments in Ghent and the vicinity. At mid-may the exhibition will be opened by the authorities. At 3 o'clock a banquet will be given at l'Hôtel Royal. In the evening a reception by Baron RAYMOND DE KERCHOVE D'EXAERDE in the hotel of the "Governement Provincial." Members of the Committee and their wives will receive a special invitation.

MONDAY, JULY 10.—Further visits will be paid to nursery-grounds in the neighbourhood. At 11 in the morning an association of old pupils of the School will be constituted; at 2 o'clock a meeting of the Committees will be held, followed by a general meeting and the closing of the Congress for forwarding horticultural education. In the evening, at 6 P.M., a banquet will be given in honour of foreign delegates and members of the horticultural press, succeeded by a fête in the Casino in the Gardens of the Société Royale d'Agriculture et de botanique, a concert, ball, &c.

TUESDAY, JULY 11, will be devoted to visiting Brussels nurseries, and the Royal Gardens at Laeken, and the houses of the Horticulture Internationale.

METROPOLITAN OPEN SPACES.—On Saturday, May 27, a new recreation ground was opened at Hither Green. The ground, given by Mr. CAMERON, M.P., is 2 acres in extent, and provides accommodation for tennis, croquet, and other games. It is worthy of record here, also that Mr. E. N. BAXTER, a gentleman connected with the Epping Forest Committee, has handed over to the Corporation to be added to Epping Forest, a beautiful piece of woodland, some 28 acres in extent.

JEWISH GARDENERS.—We learn from the last issue of the *Gartenflora* that besides the Jewish Training Institute at Ahlem, near Hanover, where for some years gardeners have been trained and educated with good results, another school has been established at Gablenz, near Gassen in Brandenburg, by Dr. S. PAPILSKY, the Vice-President of the Society, for the advancement of agriculture among the Jews in Germany, at which students will be enabled to acquire theoretical and practical knowledge. Certain of these students have already been through the course of instruction at the establishment at Ahlem. It is Dr. Papilsky's intention, when a suitable number of young people have given proof of their intention to join, to establish a private school of agriculture. With the view of making propaganda the Doctor has undertaken to publish an address-book of Jewish landowners, tenants of estates, and stewards.

Royal Seedsmen.—The well-known firm of Kent & Brydon, Darlington, desire us to inform our readers that they were, on June 1, appointed by Royal warrant, seed-merchants to H.R.H. the Prince of Wales.

Hybrid Anthuriums.—How M. A. de la Devansaye's efforts in improving Anthuriums were appreciated in St. Petersburg, is illustrated by the fact that he obtained the great gold medal, together with a special prize for the finest lot of stove plants raised by the exhibitor, a large silver-gilt medal for six new seedling Anthuriums, and for the Anthurium Fraxinense ×.

The Scottish Horticultural Association.—On Saturday, May 27, the members of the Society of Gardeners paid a visit to Sir Charles Tennant's garden, "The Glen," near Innerleithen; Mr. R. Laird, Secretary, and Mr. Todd, Vice-president, accompanying the party. We shall shortly give some illustrations of "The Glen," and reserve further remarks until these are inserted in our pages.

Ferns.—Professor Bower, in a recent number of the *Proceedings of the Royal Society*, May 25, 1899, pursuing his researches into the genealogy of Ferns as a basis of classification, says:—"An attempt has been made in this memoir to strengthen the characters derived from the sorus by a fresh examination of its details, and certain of its features will now be used for purposes of general comparison which have hitherto received too little attention; they are:—

1. The relative time of appearance of sporangia in the same sorus.
2. Certain details of structure of the sporangium, including its stalk.
3. The orientation of the sporangia relatively to the whole sorus.
4. The potential productiveness of the sporangium as estimated by its spore-mother cells, and the actual spore-output.

Observations of these features extending over all the more important living genera, coupled with data of habit and the characters of the gametophyte (prothallus) as collateral evidence, have led the author to divide the homosporous Ferns thus:—

Simplices	Marattiaceæ	Eusporangiatæ.
	Osmundaceæ	
	Schizæaceæ	
	Gleicheniaceæ	
	Matonineæ	
Gradatæ	Loxsomaceæ	Leptosporangiatæ.
	Hymenophyllaceæ	
	Cyatheaceæ	
	Dicksonieæ	
	Dennstaedtiinæ	
Mixtæ	The bulk of the Polypodiaceæ	

These divisions are primarily based on the order of appearance of the sporangia in the sorus, the Simplices having all the sporangia of the sorus formed simultaneously, the Gradatæ having them disposed in basipetal succession (from above downwards), and the Mixtæ having the sporangia of different ages intermixed. But it is found that other important characters run parallel with these. Thus the Simplices and Gradatæ have an oblique annulus (where definitely present), the Mixtæ (with very few exceptions) have a vertical annulus. None of the Mixtæ have been found to have a higher spore-output per sporangium than sixty-four, but this number is exceeded by some of the Gradatæ, and large numbers are the rule in the Simplices. The Simplices and Gradatæ have relatively short thick stalks, the Mixtæ usually have long and thin stalks. The orientation of the sporangia in the Simplices and Gradatæ is usually definite, in the Mixtæ it is indefinite. The receptacle is often elongated in the Gradatæ, but not in the Simplices or Mixtæ. The sum of these characters, which for the most part run parallel to one another, appears to give a substantial basis to the classification."

Bulb Cultivation in Ireland.—We note in the Dublin papers that early last week, the quaint and usually tranquil village of Rush, Co. of Dublin, was roused from its normal condition by the bustle and excitement incidental to a Vice-Regal visit. Messrs. Hogg & Robertson, seedsmen to Her Majesty, Dublin, were honoured by a command to receive Countess Cadogan, wife of the Lord Lieutenant, who, attended by Mr. Algernon Peel, Private Secretary, made an extended inspection of their bulb-farm. The Narcissus and Early Tulips were of course over, but the May-flowering species and Darwin Tulips, Ranunculus, and Anemones, were at their best, and the wealth of bloom made a magnificent display. Her Excellency was pleased to express her satisfaction with her visit, and was specially struck with the large and varied collection of late Tulips. Messrs Hogg & Robertson were honoured with an order for a large collection of Daffodils and Tulips to be sent in the autumn to Culford Hall, Earl Cadogan's residence, near Bury St. Edmunds.

Publications Received.—*Bulletin della R. Societa Toscana di Orticultura*, April.—*Tijdschrift voor Tuinbouw*.—*Botanical Magazine* (Tokyo).—*Flora Japonica iconibus Illustrata* (Tokyo).—From the Crystal Palace Company, Sydenham, London, a programme of arrangements for the forty-fifth season (1899). Among the events most interesting to us, are the National Rose Society's Exhibition on July 1; the exhibition of the Carnation and Picotee Society on July 24; the Great Co-operative Show on August 19; the National Dahlia Society's Show on September 1 and 2; and last, but not least, the Exhibition of British-Grown Fruits by the Royal Horticultural Society on September 28, 29, and 30.

PLANT PORTRAITS.

Chrysanthemum Souvenir de Madame Hélène de Reydellet, *Moniteur d'Horticulture*, May, 1899.

Erodium Manescavi, *Garden*, April 29.

Hibiscus cannabinus, *Garden*, April 15.

Liatris pycnostachya, *Garden*, April 8.

Passiflora amabilis, *Garden*, April 22.

Sorbus aucuparia dulcis, Beissner, in *Gartenwelt*, iii.

Statice Suworowi, *Revue de l'Horticulture Belge*, May.

KEW NOTES.

The following interesting plants are now flowering at Kew:—

Lonicera Hildebrandiana.

This, the largest-flowered of all the Honeysuckles, was introduced from Upper Burma in 1894, but it has only now flowered for the first time at Kew. It has two-flowered axillary racemes, and each flower is 6 inches long, and is coloured bright golden-yellow. A figure of it has been prepared for the *Botanical Magazine*. Although tried under various conditions, it has only succeeded in the intermediate temperature of the Mexican-house. At Glasnevin, however, where it flowered in August last year, Mr. Moore grew it in a sunny, airy position in a greenhouse. It was figured in the *Gardeners' Chronicle*, Sept. 17, 1898.

Rhododendron decorum.

This is one of the Yunnan species which we owe to l'Abbé Delavay. It has been in cultivation ten years at Kew, where it is now flowering in the open air for the first time. It seems to be nothing more than R. Fortunei, which was introduced by Fortune from Chekiang, China, and figured in the *Botanical Magazine*, t. 5596 (1866).

Rhododendron Championæ.

Although cultivated at Kew for nearly twenty years, this interesting plant has only flowered two or three times. It was found fifty years ago by Captain Champion, growing abundantly on rocks in a ravine at Fort Victoria, Hong-kong, and a figure of it made by him was published in the *Botanical Magazine*, t. 4609 (1851). It is remarkable for its hairy dark green, wrinkled leaves, and large pink, Azalea-like flowers. It is now in flower in the Himalayan-house.

Rhododendron Kingianum.

This plant was found in Munipur by Dr. Watt, who sent specimens and seeds of it to Kew, where it has formed a bush 5 feet high, and is now flowering for the first time. Broadly speaking, it is a form of the variable R. arboreum, and is nearest that known as R. Campbelliæ, but it differs from this and all other forms by its dense habit of growth, wide leaves, which are distinctly bullate, with recurved margins, very dark green above, dull dark brown below. The flowers are in dense conical heads, and of a rich crimson colour. In botanical characters they agree with typical R. arboreum.

Protea cynaroides.

This handsome Protead continues to grow and flower freely along with the Agaves in the Succulent-house, where it is now bearing three large Artichoke-like heads of a soft, pink colour. It is planted in the gravel bed, upon which the Agaves, &c., in pots are stood, and it gets plenty of air and sunlight at all times.

Impatiens mirabilis.

An exceptionally large specimen of this remarkable species has lately been forwarded to Kew by Mr. Curtis, of Penang, and it is now in full leaf and flower. The fleshy stem is 3 feet high, with three arm-like branches; the base 8 inches in diameter, the habit suggesting a minature Baobab. The leaves are ovate, 8 inches by 3 inches, and the golden-yellow scoop-shaped flowers are borne in short axillary racemes. Sir Joseph Hooker, when figuring this species in the *Botanical Magazine*, in 1891 (t. 7195), said, "It would be difficult to conceive a wider departure from the habit of its genus than this plant presents. It is an undoubted Impatiens, but whereas the other species are weak succulent annuals, or low-branched perennials, I. mirabilis possesses an erect naked trunk 4 feet high, and as thick as a man's leg, crowned with a tuft of many fleshy leaves, nearly a foot long." It is a native of Langkawi Island.

Lachenalia quadricolor.

By far the handsomest form, both as regards size and colour, of this distinct Lachenalia, is now flowering in the Cape-house at Kew. It agrees with the figure in the *Botanical Magazine*, t. 588, in having flowers coloured red at the base, yellow in the middle, and rich purple on the upper part of the inner segments, but it differs from that figure in having scape and leaves mottled with brown. It was sent to Kew by Mr. Butters, St. George's Park, Port Elizabeth.

Renanthera Imschootiana.

This beautiful Orchid improves on acquaintance. It was first described in 1891 from a plant flowered by Mr. Van Imschoot; Mr. Woodhall showed it in flower at a Drill Hall meeting in 1895; and in the year following, Messrs. Sander & Co. secured a small importation of it. One of these plants is now in flower at Kew, and although only 8 inches high, it has produced a scape 18 inches long, with three branches and thirty flowers, which are nearly all open. At first they are coloured bright crimson, but they gradually change to a rich old golden-yellow colour. The flowers have all the brilliance of those of R. coccinea, but the plant promises to be a better garden Orchid, in that it blooms in a small state. It is a native of Assam, and has been called R. Papilio.

Phalænopsis tetraspis.

Although introduced about ten years ago from the Andaman Islands, this species is rarely seen. A plant of it is now bearing a spike of creamy-white flowers in the Orchid-house at Kew.

Masdevallia muscosa.

The mossy-scaped species, with a sensitive-lipped flower, is represented by a large tuft at Kew, and is now in flower.

Eulophiella Elisabethæ.

This plant has found a congenial home at Kew, as it grows there with exceptional vigour. This year it has developed two lots of flower-spikes, four in February and four in May. The fog destroyed two of the first lot, and it was considered advisable to remove two of the second. Those left on are now bearing each about twenty flowers.

Coryanthes macrantha.

A fine plant of this, the phenomenal "bucket-orchid," bore a spike of two flowers in the Nepenthes-house a fortnight ago, and it is now pushing a second spike. Those who have never seen the flowers of this plant should not miss this opportunity. C. maculata flowered freely in the same house last year, and a wax model of the flowers was prepared by Miss Emett. *W. W.*

LAW NOTES.

THE PREVENTION OF CORRUPTION.

At 4.15 the House of Lords, June 6, met for the despatch of ordinary legislative business, and Lord Russell of Killowen at once moved the second reading of his Prevention of Corruption Bill. He said that the contents of the Bill had already been so fully explained that it was only necessary on the present occasion to say that the object of the Bill was to check by making them criminal a large number of inequitable and illegal secret payments. The principle of the measure had been received favourably by chambers of commerce, trade societies, and various co-operative associations throughout the country, and an almost unanimous opinion had been expressed in favour not only of the principle, but also of the stringent measures by which he proposed that the principle should be enforced. He did not desire their Lordships to understand that the various bodies to which he had alluded entirely approved of all the details of the measure, and, indeed, it was his intention to propose some amendments.

The Bishop of London said that the bill was concerned with all commercial dealings between man and man. It dealt with a common mischief, the principle of which was that no money was to pass from one person to another without some of it sticking to the fingers of some intermediate party to the transaction, and that mischief tended to destroy trust, to prevent people from being strictly honest, and to shake confidence. There was a time when even the occupants of the judicial bench received gratuities from those who were parties to litigation before them. The payment of gratuities was undesirable in itself, and also because it gave opportunities for blackmailing.

The Bishop of Winchester also warmly supported the principle of the bill.

These points were generally endorsed by the Lord Chancellor, who, however, warned the House against the danger of going too fast in legislation of this character. He concluded, however, by saying that he heartily concurred in the general object of the measure, and that the Government were not in the least disposed to offer opposition to the second reading.

Lord Russell briefly replied, and the bill was then read a second time.

Garden Labourers and the Excise.

An Important Appeal Case.

Before Mr. Justice Day and Mr. Justice Lawrance, sitting as a Divisional Court in the Queen's Bench Division of the High Court of Justice, the case of Dillon *v.* The Marquis of Bath came on for discussion on Thursday. The Attorney-General, Sir R. Webster, and Mr. Dankwerts appeared for the appellant, and Mr. Foote, Q.C., and Mr. Scott for the respondent.

The Attorney-General said this was a case stated by justices of the county of Wiltshire, and raised the question whether a certain number of men, employed by the defendant, were chargeable as gardeners or servants under the statute relating to the taxes on servants employed. The point depended on the facts and on the construction of the statute. They, on behalf of the Inland Revenue, submitted that the view taken by the magistrates was wrong, and that having regard to what the men did, they were clearly within the statute. The case stated that an information was laid against the Marquis of Bath, by the appellant, charging him with employing, at Longleat Park, a number of male servants without having taken out a licence for each of them. The summons was heard at Warminster, and it was proved that the Marquis had taken out licences for a number of gardeners and under-gardeners, but with regard to ten men and two boys, who were employed in the gardens, no licences had been obtained, and it was these persons as to whom the question arose. The appellant submitted that they did work which could only be properly described as gardening, and therefore a license was required under section 18 of the statute.

On behalf of the respondent it was contended that such persons were merely unskilled labourers, receiving labourers' wages only, and therefore did not require to be licensed, but he (counsel) should contend that there was no distinction at all for the purpose of this taxation between skilled and unskilled labour. If a man did gardening work, it did not prevent him being taxable if he was not a skilful person. Take the case of planting Cabbages. It was said skill was required, and if he were to try and do it he might make a bad job of it. He agreed that the mere fact of the men being employed in the garden did not constitute them gardeners, but because these men divided the ordinary duties of a gardener among them, that did not make them merely labourers. One might do the digging, another the planting, another the watering, and so on, but they would nevertheless be doing gardeners' duties. Therefore, he submitted, the magistrates were wrong in holding that the men were merely labourers, and not servants within the meaning of the Act, and, therefore, a licence was not necessary.

Mr. Foote, for the defendant, submitted that the magistrates were right, and said the courts had taken a view which he now contended for. It was a mistake to suppose that because a man was employed in a garden he was a gardener. He might be employed all day in simply dragging a roller about, and, whatever he was, whether he was a beast of burden or doing donkey-work, he was certainly not a gardener. A gardener must be a person skilled in tending a garden, and not doing such work as wheeling a barrow about or digging.

After further argument Mr. Justice Day said he thought the decision of the magistrates was perfectly correct. They came to the conclusion that the men were labourers, and he thought it was essentially a question of fact for them to determine, as they lived in the neighbourhood and knew what the men were. He thought the distinction whether they were skilled or unskilled made all the difference, and was most material to consider. Therefore the appeal must be dismissed with costs.

Mr. Justice Lawrance concurred, and said he did not see how any of these persons could possibly be described as gardeners or under-gardeners.

Appeal dismissed with costs.

Alleged Fraud on a Gardener.

At the North London Police Court on Thursday, 1st inst., George Clark, an elderly man, described as a clerk, of Nursery Road, Tottenham, was charged on remand, before Mr. Bros, with obtaining money from different persons in various parts of the country by false pretences. Two cases from Maidstone and Hayward's Heath were gone into last week, and other charges were now proceeded with. Harry Howard, gardener to Mr. Edward Brooke, J.P., of Ufford Park, Woodbridge, Suffolk, said that on October 1, he inserted an advertisement in the *Gardeners' Chronicle* for 150 young Yew-trees. He received a post-card purporting to come from "T. Riley, 60, Drayton Park," offering to send on 150 Yew-trees if a postal order for 30*s*. were forwarded. The writer added that his employer, Mr. J. J. Griffiths, J.P., of No. 1, Highbury Grange, was away, so that he was unable to get a cheque cashed. The witness sent on the postal orders, but the Yews never arrived, and the money was never returned. Mr. Fred Griffiths, coal-factor, of 1, Highbury Grange, said that Mr. J. J. Griffiths, J.P., was his father. The prisoner was not his gardener, and he had no authority to use his name. Various other cases were alleged, and in the end the prisoner, who made no denial, asked to be dealt with at once.

Mr. Bros committed him to the Central Criminal Court for trial.

HOME CORRESPONDENCE.

NEW VARIETY OF DAFFODIL, WHITE LADY.—We have one of the Rev. G. Engleheart's seedling Daffodils, which, we think, is a break away, in so far as our experience goes. On April 15, we exhibited blooms at Edgbaston Botanical Gardens, which were cut from bulbs in the open and fully expanded in a glasshouse. The bed gave a show of bloom for a period of ten days from that date, and the bulbs have been sending up a few blooms till the present date, each lot being smaller than those that preceded them. Those we send for your inspection appear to be the last, and they are less than half the size of the flowers at their best. It is unusually prolific in foliage and flower. We should be glad to hear if any cultivator of Daffodils knows of any similar variety. We know that it is no uncommon thing to get a few late blooms from weakly or deep planted, or injured bulbs, but the bulbs of this variety are quite healthy, and they are growing under suitable conditions. *Pope & Sons, King's Norton.*

MILDEW ON VINES: CAUSE AND PREVENTION.—Sometimes violent remedies are worse than the diseases they attempt to cure; and I consider that prevention is better than cure. I never yet saw mildew in a well managed vinery. It is encouraged generally by a cold draught, admitted by front ventilators, and not warmed by passing over hot pipes. A low temperature, and damp, stagnant atmosphere encourage the growth of mildew; and a genial atmosphere, proper ventilation and moisture, are preventives. After the thinning is finished, a little soot and sulphur placed in the evaporating pans will help to keep all sweet and healthy. In a genial, kindly summer out-of-doors, Vines in the south of England will ripen good crops of Black Hamburgh and Sweetwater Grapes, but if we get cold winds and damp, unseasonable weather, they are destroyed by mildew. Tea Roses trained to dwelling-houses are affected by the same cause. I should consider that boiling water needs to be used with great care, and Mr. Mallet would do good service if he stated at what stage the Grapes were when he applied the hot-water cure. *R. M. Newbury.*

—— In last week's issue of the *Gardeners' Chronicle*, p. 353, is an account of a method of treating the Vine-mildew by thoroughly syringing the Vines with water at the boiling-point. [Not used at the boiling-point. Ed.] I should not like to try the experiment on any plants upon which I set any value, for I feel sure it would destroy it. I have used hot-water with good effect in destroying insects infesting plants, but not hotter than 170°, and even then it destroyed all kinds of insects without injuring the plants. I never tried water at this temperature on very tender plants, although in the case of some Streptocarpus which I dipped in water at 170° quickly all the mealy-bug infesting them was killed, and the plants were not hurt at all. I am of the opinion that water at 170° is a safe and efficient insecticide, as well as cheap. When a plant is syringed with hot-water, it should be laid on its side, so that the water cannot penetrate the soil and injure the roots. *Wm. Smythe, Basing Park Gardens, Alton.*

—— I read Mr. Mallet's note on Vine-mildew in the issue of the *Gardeners' Chronicle* for

May 27, and my Vines being attacked with mildew, I tried the hotwater remedy, the varieties being Black Alicante and Gros Colman. The water acted precisely as he describes it, brown spots, showing where the mildew had been on the leaves and Grapes. Boiling-water was used on Vines, which were unaffected with mildew, and no injury whatever was visible on the foliage or fruit. *G. Littlewood, Worthing.*

PROPOSED MEMORIAL TO THE LATE MALCOLM DUNN.—I was glad to see the note of "J. S." in the *Gardeners' Chronicle* last week. He may rest assured that something worthy of the man and the occasion will be done, though those mostly concerned did far better than erect a testimonial to the dead—they honoured M. Dunn while living, and few gardeners have died more full of honours than the deceased. I have heard, however, that three Scottish societies have already had this matter before them, the Royal Caledonian, the Scottish Arboricultural, and the Scottish Horticultural Association. It seems very desirable that these societies should combine their forces with the Royal Horticultural Society of London, and any other that might wish to share in the work throughout Great Britain and Ireland, in some common purpose. But no money should be wasted in monuments or such like memorials. They would be singularly out of place here. The deceased's life and work form his most lasting record. But, perhaps, a scholarship for young gardeners, or an endowment to the Gardeners' Orphan Fund, or the Gardeners' Benevolent, bearing deceased's name, would be the best form of memorial, most helpful to gardeners, and that would have commanded M. Dunn's approval. An objection in advance has been raised by some arboricultural friends, viz., that the orphans of foresters are not eligible for election as pensioners on the Gardeners' Orphan Fund. But surely this could be readily arranged by making foresters' orphans eligible for election under the Dunn Trust. The one vital point is to secure united action in the matter, and to see to it that whatever scheme is adopted, it shall benefit the living as well as honour the dead. *D. T. Fish, June* 3.

THE USES OF RHUBARB.—There are round London alone enormous quantities of Rhubarb which goes to waste for lack of some means of utilising it. I have just seen in one of the early numbers of the *Midland Florist*, some suggestions for doing this, which may be of service to some of your readers. One is:—"To preserve Rhubarb without sugar or the trouble of boiling. Gather the Rhubarb in September, cut the stems into pieces about 3 inches in length; procure some wide-mouthed glass jars, and fill with the pieces of Rhubarb; then fill up the jars with cold spring-water, and cork tight, or tie over the mouth a piece of bladder, or use any other method which will keep the bottles perfectly air-tight (it is of the utmost importance they be hermetically sealed), and then the Rhubarb will keep till after Christmas." The person who sends this, remarks: "I have to-day (January 6) eaten of a tart of Rhubarb so preserved, and in flavour it was quite equal to the spring-grown Rhubarb, and much superior to early-forced." Another method of preserving Rhubarb is "To cut it as for tarts, and to every pound put three-quarters of a pound of sugar, and boil three-quarters of an hour thoroughly on a slow fire, stirring it occasionally. This has very much the flavour of Orleans Plums." "Rhubarb syrup.—Cut the Rhubarb as usual, then put it in a jar, which place in a pan of water till the Rhubarb is reduced to a pulp; then press it through a cloth. To every pint of juice put one pound of sugar; mix, and put on to boil; let it boil five minutes, and then stand till nearly cool. Pour the syrup into small phials—those formed of thick, dark glass are best, as the syrup is apt to ferment in thin ones. Any fruit may be made use of in this way, but Raspberries and Currants need only be pressed, not stewed. The syrup, with water added, makes a nice drink, or is valuable to whisk with cream, or for puddings." The last is—"To bottle Rhubarb.—Take the stalks in fine weather, prepare them as for tarts, then put them on in a pan with water enough to cover them; when it becomes so warm that you can only just bear your hand in it, pour the whole through an earthenware colander into a jug. Have ready wide-necked bottles, fill them with the fruit, and then pour the warm water in so as to cover the Rhubarb; tie a covering of bladder on each bottle, leaving them in the kitchen until it dries on, and then put them in a cool place out of the way of frost and damp. When wanted for use boil the Rhubarb-water till reduced to a little before you put in the fruit; this will require very little time to cook. It may be as well to mention that the bladder used will require often and careful washing in luke-warm water, and that the bottles answer better to be clear and transparent, the Rhubarb not keeping so well in dark ones. Gooseberries may be preserved in the same way." *D. R.*

DOUBLE DARK WALLFLOWERS.—Two varieties of double dark Wallflowers, Negro and Negress, have been cultivated in Lancashire gardens for many years past. The latter is the older in point of time, and Negro has always been regarded as the better one, having mulberry-coloured flowers, and a fine spike; excellent in colour, very double, and of good habit. This, it is said, was raised from seed by a Mr. Charlton. The Lancashire cottage gardens, at one time forming pleasing features on the outskirts of large towns or centres of industrial enterprise, are rapidly disappearing from many localities; houses and factories take their place. But now, in many of them, very choice old-fashioned things can be found by anyone who has the leisure to explore them. Not a few of the Lancashire operatives who possess gardens know the value of choice things, and they have always held that a good thing in a garden takes up no more room than a bad one. If one makes Middleton a centre, it would be found that within 2 or 3 miles of it are gardens which would well repay an inspection because of the interesting things to be found in them. *R. D.*

IBERIS PERFECTION.—When manager to Messrs. Dicksons & Co., I added to my love of hardy and other plants the improvement of the perennial Candytufts, and raised at Leith Walk, I. superba; and after removing to Pilsig Park the following were introduced, Climax, capitata and Perfection, and so far as I know, the first to take in hand the improvement of these beautiful and hardy border plants. *James Grieve, Redbraes.*

RHUBARB-SPINACH has been for many years a favourite dish with us when we could not get the true article. The young shoots of the Poke-berry (Phytolacca decandra) are also very nice when boiled. *W. T., Teignmouth.*

RASPBERRY-BUD CATERPILLAR.—I have to report a bad attack of the Raspberry stems and bud caterpillar (the larvæ of a moth, Lampronia rubiella). I was visiting Claverley, near Bridgnorth, on May 12 last, for the purposes of lecturing and demonstration; and on visiting the gardens at Farncote House, the lady—Mrs. Haslehurst—called my attention to the Raspberry canes, which had the appearance of having been severely cut by frost; most of the leaves and young shoots being very brown and withered. On examining some of the shoots the dark-red caterpillars were seen in the centre of the terminal buds, which had been eaten off. I sent afterwards for some specimens, but no caterpillars could then be found; they having doubtless passed into the chrysalis stage. The attack was so bad that I could only recommend the destruction of the Raspberry bed, there being no prospect of any crop the present year. Miss Ormerod gives a very good description of this moth, its life history, mode of attack, prevention, and remedies in her handbook of *Insects Injurious to Farm and Garden Crops*, and according to her account, it is by no means very prevalent, not being noticed by her before 1883, as "markedly injurious." Wherever observed, measures should be taken forthwith to prevent its spreading, either by breaking off the infested buds and shoots and burning them, or syringing the canes with some of the insecticides in common use. If the attack is a very bad one, it is the more prudent course to destroy the canes, well till the ground, and plant a vegetable crop, fresh plantations being made elsewhere in the autumn. *A. Gaut, Shrewsbury.* [This has been repeatedly figured in the *Gardeners' Chronicle*, the latest occasion being on May 9, 1896, p. 595. Ed.]

OLD FLOWERS AND THEIR GROWERS.—Reminiscences, such as those about Tulips, by "R. D.," on p. 55, are both interesting and instructive, if only for the illustrations they portray to the younger generation of florists, concerning the change in fashion, systems of culture, or the methods employed by our forefathers in their endeavour to perpetuate a fancy for such flowers as were popular and recognised by a numerous class in their day. The florist's Tulip in particular was one of the foremost of these specialties, and it is interesting to note what the old nurserymen, both English and Dutch, of a century ago, catalogued in this direction. In turning to the pages of the booklet issued by Messrs. Voorhelm & Schneevoght in 1798, and printed in Haarlem, we find amongst the class described as byblœmens, La Fraise en Crème, which I take may be translated as Strawberries in cream, priced at 150 florins each; whilst for Louis XVI., No. 1 selection, 150 florins is asked; for No. 2 selection, 100 florins each. Many other Tulips are priced at 60, 40, and 30 florins each. Among the Tulip bizarres is found Vainqueur universel, 150 florins. In the catalogue of this same firm for 1801, these values seem to have been maintained; whilst in 1805, the No. 2 Louis comes down to 75 florins; in the same list, Grand Monarque Narcissus is priced at 3*s*. each. Richard Clarke, florist, at Cambridge, offers in his catalogue dated 1793, several kinds of Auriculas at 31*s*. 6*d*. each; Carnations at 10*s*. 6*d*.; Ranunculus, 1*s*. to 21*s*. per root; Anemone seed, 18*s*. per lb.; Polyanthus seed, 31*s*. 6*d*. per oz.; Carnation seed, 105*s*. per oz. James Davey, florist, of Camberwell, offers in 1798, 100 Tulips for £10, whilst Tulip Princesse de Wirtemberg is figured at £50 each; Dowager Countess of Aylesbury, with a fine white bottom, £100 each; and Gloria florum suprema, £300. This same James Davey seems to have removed to King's Road, Chelsea, for in his list of 1805, dating from there, he offers the fine Byblœmen Tulip, La Joie de Davey, in large type, at £500 per bulb; he also asks £1 1*s*. for Lord Nelson Carnation, 15*s*. each for certain Ranunculus, whilst for his black-and-green Auricula he asks 31*s*. 6*d*. He invited free admission to see his Carnations, which were to be in full bloom on July 15, 1798; his best were priced at £5 each. This nurseryman seems to have possessed a fine collection of Ericas, for he offers fifty different sorts for 10 guineas. In the catalogue issued by Valentin Schertzer & Son, from their Magasin at Haarlem, in 1807, no fewer than fifty varieties of double black Hyacinths are quoted at prices ranging from 6 guelders to 6 florins each, whilst 20 guelders are asked for a Byblœmen Tulip. Double Lilium candidum is figured at 4 florins each, and a yellow African Gladiolus at 12 florins each. Goring & Wright, successors to Maddocks & Son, Florists, Walworth, offered, in 1798, several double red Hyacinths at £8 8*s*. each; and it is remarkable to note, whilst some five pages are devoted to the doubles, three lines only are given to single Hyacinths, and these are offered at from 1*s*. to 3*s*. per dozen. Their most expensive Tulip was a yellow bizarre called Superbissima for which 15 guineas was asked. They also offered double white Lilies of the Valley, 1*s*. 6*d*. each; yellow spotted Picotees, from Italy, from 2*s*. to 42*s*. each; double white Violets, 2*s*. 6*d*. each; silver-striped Strawberry plants, with scarlet fruit, 5*s*. per hundred; and a curious late transparent Pea, price 5*s*. per quart. John Mason, of the "Orange Tree," 152, Fleet Street, in his list for 1800, offered some Double Red Hyacinths at 105*s*. each. His most expensive Tulip is £20 per bulb, but many are offered at £10. No fewer than twenty-eight pages are devoted to Ranunculuses and Anemones, showing what important flowers they were in his day. In James Carter's Bulb Catalogue for 1843, these fabulous figures seem to have disappeared, for his most expensive Hyacinth is 7*s*. 6*d*., and the highest-priced Early Tulip is 1*s*., and the Florist's or Late Tulips 4*s*. each. Truly a great fall from the figures of forty years previously. He offers the Siberian Scilla at 6*d*. each, he also has a Snow white Gladiolus at 20*s*. each. An old print gives a faithful picture of a meeting of old-time florists at a public-house sitting-room in the suburbs of London. It will be seen they are discussing the merits of a novelty, probably an Auricula or Polyanthus; and the tankards of beer and churchwarden pipes take a leading place in the affair. It was a free-and-easy custom of the day, and differs materially from the methods followed at the present time; yet in their simple way I have no doubt their knowledge was as advanced in the particular points they had in view as our own. *Donald McDonald.*

THE PARADISE STOCK.—As one of the first to plant, prove, and commend the general cultivation of Apples on this healthy fertile stock, I do not wonder that the usually placid Mr. Geo. Bunyard seems a little ruffled, on page 354, at a recent attack made on its health and longevity. Some years ago is also too vague, and may mean many, any number from five to fifty years. Then I have been planting Apples on this Paradise for a period nearer this latter than the former, and I do not remember a single one of them wearing out or dying down of weakness, old age, or disease. In my lecturing and other tours, I have also seen and noted thousands of Apples on the Paradise, their leading features being good health, abnormal fertility, compactness, and symmetry. Naturally, we are hardly likely to find so many old Apple-trees on the Paradise, as the general use of the Paradise as a stock for our Apples is a modern improvement in fruit-culture, comparatively of yesterday. But as a matter of practical experience, I can add ten to fifteen years to Mr. Geo. Bunyard's thirty, and these venerable trees of forty or forty-five years old are bearing as good crops as ever. Yielding annual crops of the finest fruits does not seem to have impoverished them, and certainly under skilful culture and good management we have not yet reached an age-limit to Apple-trees mounted on the Paradise. I do not mean to assert that all Apples worked on the Paradise are alike healthy, fruitful, or long-lived, as all Paradise stocks are not the same or good alike. Soils, site, skill, and treatment, are of various kinds that greatly influence the health and longevity of Apple and other fruit-trees; but I cannot admit for a moment that a good strain of Paradise stock necessarily shortens the life of the tree. *D. T. F.*

MAKING ROOM AT THE TEMPLE SHOW.—That without enlarging the area of the tents at the Temple Gardens it is possible to make provision for greater variety of exhibits, there can be no doubt. Thus, whilst the finest groups, thinly and artistically arranged, of Japanese Acers were outside, two or three groups of these plants were occupying space in the tents, very much crowded, and greatly losing in grace and beauty, as compared with the pleasing effects produced by the outside groups. Surely all these can be put outside another year. Growers of Caladiums may, perhaps, object to the suggestion, but these plants show so little variation from year to year that they might for once be left out of the show schedule, and something else be substituted. Some things, which no one cares specially to name, are exhibited in too large numbers, necessitating great repetition. These things would rather gain than lose, if but one half the number of plants were staged, and those rather more thinly. It seems odd that whilst Begonias loom so bulkily, and with great sameness, we see no representation of Show, Fancy, zonal, Ivy-leaf, or other Pelargoniums, or of Fuchsias. Orchids, beautiful as they are, become monotonous when twenty collections are but reproductions almost one of another. Did exhibitors put up distinct families or genera, or restrict themselves to Cattleyas, or Odontoglossums, or Dendrobiums, &c., then the result would be very interesting. Orchids do seem to get by far the lion's share of the tent-space, and yet they are far from being everybody's plants. A considerable pruning of the space allotted to some exhibitors, thus enabling other descriptions of plants to be staged, would harm no one, and help to make the show more varied and attractive. There is no fear of having too much of forced fruit; even more than was seen at the recent show would be welcome if as good. But of vegetables, far too much that is mere packing, or of inferior merit, was seen, and some limitation might well be put on dishes, or varieties shown which should be of the very best only. *A. D.*

HARD AND SOFT WATER.—During the present hot weather, many gardeners may be obliged to use hard water to their plants, which is known to greatly injure certain species. I have been told by Mr. Le Pordevin, a nurseryman in Guernsey, that his spring water is exceedingly hard; when he is obliged to use this water he puts 4 ounces of common washing soda in each 50 gallons. He first dissolves the soda in a little warm water and places the whole in a tank, allowing it to stand twelve hours before using. The soda acts on the other minerals of the soil, and thus becomes a conveyer of plant-food to the tissues of the plants, and consequently feeds as well as waters the plants to which it may be applied. *J. J. Willis, Harpenden.*

CYPRIPEDIUMS.

IN the struggle for existence among fashionable Orchids, Cypripediums easily hold their own. Like Tennyson's brook, "Orchids may come, and Orchids may go, but Cypripediums go on for ever." Nor is the reason far to seek. The great majority of this distinct group are plants of easy culture, quick propagation, and reasonable price. This last consideration is by no means the least; as the writer of these notes has found, one can get together a large collection of Cypripediums without going to the expense and trouble of becoming a millionaire.

Cypripediums are by no means so gorgeous as the aristocratic Cattleyas, nor so dazzling as the ephemeral Dendrobiums, nor are they so graceful as the delicate Odontoglossums; yet all these drawbacks are amply made up in Cypripediums by the extraordinary range of variation they present, the great durability of their flowers, and their evergreen and variegated foliage, handsome all the year round. Thanks to recent advances in hybridisation, the dull and sombre hues of some of the larger species have been eliminated, the brilliant shades of the smaller species have been combined with the graceful forms of the larger ones, thus evolving new types superior in every way to the old natural species. All these things have tended to maintain the popularity and increase the interest in Cypripediums.

At the same time, a difficulty has arisen in the undue multiplication of Latin names for all these new forms and varieties, a difficulty which threatens to overwhelm the amateur when first starting a collection. It is with much pleasure, therefore, that we received lately the new edition of M. Desbois' well-krown hand-book, first published in 1888, and already mentioned in these columns. A comparison of the two editions impresses one with the remarkable advances of hybridisation during the past ten years. In the original edition about 150 species, varieties, and hybrids of Cypripedium were described; while in the new edition the number is increased to considerably more than 1000; in fact, nearly 1100 named forms are described.

Necessarily the work has been chiefly one of compilation, the descriptions being drawn from the leading publications on the Continent, in England and America, the *Gardeners' Chronicle* naturally holding a conspicuous place. In addition to these published descriptions, we have original notes by the author, of the varieties that have come under his own observation.

After a short introduction, we have a few notes on the geographical distribution of Cypripediums in a state of Nature. The author divides them into three groups, viz:—(1), about thirty species inhabiting the temperate regions of both the Old and New World; (2), about fifty species growing in the tropics of the Old World; and (3), about fifteen species in South America. This seems to be a fairly natural way of grouping Cypripediums in a natural state, though it should be pointed out that three of the South American species form a distinct natural group of themselves, by reason of their tall reed-like habit, their plicate leaves, persistent perianth, and globose seeds, but as none of the three appears to be in cultivation, we will not dilate on this point.

Short cultural notes are given for each group, those referring to the culture of hardy Cypripediums are particularly interesting and instructive, and are well worth reproducing here, for the sake of those gardeners who do not read French:—

"Cypripediums, generally, are found in marshy places, especially the North American species; these, for the most part, come out of peaty bogs. Often one finds them growing in sphagnum-moss and decayed vegetable matter, but seldom in earth. As regards shade and light, the species have somewhat varied tastes; for example, the beautiful C. spectabile (Salisbury) does not like to be exposed to the direct rays of the sun, and only develops itself perfectly when in partial shade; on the other hand, the little C. humile, Salisbury (C. acaule, Aiton), does not mind whether it has sun or not. Of other species in the United States, C. candidum (Willdenow) and C. arietinum (R. Brown), grow in peaty places where the roots are always wet, but the stems are entirely exposed to sunlight. The two species with yellow flowers, C. pubescens (Willd.) and C. parviflorum (Salisb.), are not difficult, inasmuch as they grow equally well in the shade or in full sunlight. They are found equally in wet and in dry places, as well as in clay soils; and they seem particularly fond of places where there is hard clay. In this respect they agree with C. calceolus (Linnæus), which always prefers a limestone soil, and which does not succeed well under cultivation unless one grows it in a hard clay soil mixed with limestone. It seems to prefer exposure to full sunlight; generally, however, it is wise to give it a little shade.

"The Siberian species, C. macranthum (Swartz), and its near relation C. m. ventricosum (Reichenbach, f.), are more difficult to deal with in gardens, but this difficulty arises, without doubt, from putting the plants into wet peat, whilst they really ought to be treated in the same way as C. calceolus. This latter species grows in company with C. macranthum, and importations of roots from the locality where they grow, contain generally a large number of C. calceolus. Under glass at York (Messrs. Backhouse & Son), C. macranthum has been cultivated with success, and has flowered well in a hard limestone soil. C. japonicum (Thunberg) is considered to be a very difficult plant to cultivate, but there is no doubt that it succeeds if grown in a clay soil instead of wet peat; it is met with naturally in damp places, shaded by Bamboos, and its fibrous roots penetrate like threads of wire into the yellow clay soil. The Siberian C. guttatum (Swartz) is perhaps the prettiest of all the Cypripediums in point of colour, white spotted with crimson; it is found on the eastern slopes of the Ural Mountains. There it is even more common than C. macranthum or C. calceolus. It grows in the forests of Birch, Pine, and Poplar, where the soil is rich in humus and constantly moist. Apparently, it is only found in the forests where the three sorts of trees, mentioned above, grow. It sprouts in the herbage and moss, and seems to desire to be submitted to the same treatment that one gives to Pyrola and Epigea. The Pelican-flower, as C. Irapeanum (Llave) is called, is found in the highlands of Mexico, at an altitude of 3000 to 3500 feet; there the conditions are such that the plants are saturated with moisture at the roots, whilst the stems are in full growth, but when the stems die down the soil is dry, and then the plant enters into a period of rest which lasts all the winter. The bad results obtained in the cultivation of Cypripediums is caused, in most cases, by placing all the species under the same conditions, generally in a moist mixture of peat; this is suitable for some species, but not for all."

M. Desbois makes some interesting observations with regard to the recent triumphs of hybridisation in the Cypripedium group, and chivalrously gives Englishmen their due as the pioneers of Orchid-breeding. The descriptions of nearly 1100 named Cypripediums, with references to figures, &c., are given in M. Desbois' book. As mentioned before, the list is divided into three groups, viz.:—

(1) Hardy Cypripediums from the temperate regions of both hemispheres, comprising about thirty-five varieties. According to the latest revision of the genus by Mr. R. A. Rolfe, this group represents the true and original Cypripedium (Linnæus). In the monograph under review, we note that M. Desbois includes Selenipedium Isabelianum (Rodr.) in the above group. This is obviously a slip; being a native of Brazil, it should be included in the third group with the South American species.

(2) Oriental Cypripediums, species, varieties, and hybrids, to the number of about 950. The new genus Paphiopedium (Pfitzer) represents this group.

(3) South American species; Selenipedium, species, varieties, and hybrids, numbering in all

about 100. The new genus, Phragmipedium (Rolfe), represents this group, except three species not in cultivation, which are examples of true Selenipedium (Rchb. f.).

We observe that M. Desbois still retains the peloriate form of Phragmipedium caudatum (Rolfe), var. Lindeni, under the obsolete genus Uropedium (Lindl.). This is unfortunate; new names are quite numerous enough without reviving old ones unnecessarily.

The names in each of the above groups are arranged in alphabetical order, a system which has many advantages; though it has its disadvantages, too, for many of the hybrids described are simply synonymous, being derived from the same cross between the same two species.

To show how thoroughly the author has done his work, one instance will suffice — no fewer than eighty-three varieties of C. insigne are described; and that it is well up to date, the inclusion of C. × Olivia, C. × Mrs. Reginald Young, and C. I. Ansoni clearly shows. Interspersed among the descriptions are twenty well-grown figures, under their respective names, one of these, C. × Excelsior Mars, being a handsome photograph. Two of the figures have somehow got misnamed, the one named C. × Marchioness of Salisbury being evidently C. × Annie Measures, and C. Fred Hardy is no doubt a misprint for C. × Mrs. Fred Hardy, a totally different plant. We are also sorry to miss the customary sign of hybridity throughout the work; without this ×, hybrids cannot be distinguished at a glance, as they should be. *C. C. Hurst, F.L.S.*

BOOK NOTICE.

OUR GARDENS. By S. Reynolds Hole.
(London: J. M. Dent & Co.)

EVERYONE interested in horticulture knows what to expect when the Dean of Rochester writes or speaks of gardening. He knows that he will be amused and interested, that old truths will be presented in a new light, and that new subjects will be so handled as to appear familiar. It is so with the volume before us. We venture to think that the garden-lover who lights on its pages, as a bee on a flower, will not leave it till he has exhausted its contents. The Dean gossips in the pleasantest style, with his old wit and enthusiasm, and his abounding charity, about the enjoyments of a garden, its formation, its components, its variations, in fact, *de omne re hortensi.* He is sound and orthodox in his gardening proclivities, so that his advice, often punctuated with humour, may safely be followed by the novice.

A second edition of so delightful a book will surely soon be called for, which will afford an opportunity for further needful revisal of the proof sheets. When we are told at p. 139, that Retinospora is a "genius" of Conifers, we are not sure whether the author may not be poking fun at the reader. The story of the Aucuba, on p. 124, must be completely inverted before its correctness can be vouched for; and how, in reference to the Lilac (Syringa), can Linnæus have "changed the title of this genus from Lilac to Syringa?" Who was responsible for calling the Philadelphus Syringa, we do not know. The mistake is so general that the unravelling of its genesis would be interesting. Certainly Linnæus could have nothing to do with it in the way here mentioned.

But these matters of detail are of little importance as compared with first principles, and we take it that the reader will be charmed with the easy flow of language, and that universal assent will be given to the following articles laid down by the Dean:—

> "More grass and less gravel.
> More flowers and less bare soil.
> More curves and fewer straight lines and angles.
> More hardy and not so many half-hardy plants.
> More arrangement and less disorder.
> More shrubs, evergreen and golden, to cheer the ungenial day."

PLANT NOTES.

HYMENOCALLIS SCHIZOSTEPHANA.

THIS unrecorded species was received with a lot of Hylines imported direct, and is presumably of Brazilian origin. At first I thought that the laciniation of the cup was due to some malformation in the flowers, especially as many of them were incomplete in the number of segments and stamens; but the bulb has now flowered with me four times, and these peculiarities have proved persistent. Leaves, six or seven, one or two being persistent, and about five issuing yearly, distichous, pedate, about a foot (or more) long, by 3 to 3½ inches wide; the leaf-stalks 2 to 4 inches long, winged, and connected at the base in a distinct neck, 3 inches long; scape, issuing from within the leaves, a foot or more in height, and bearing twelve to twenty sessile flowers in an erect, crowded umbel; flowers bearing a general resemblance to those of H. angustum of *Bot. Reg.*, 221, but the filaments very stout, and winged at the base, thus forming an irregular torn-looking cup; tubes green, 2 to 3 inches long; segments about equal in length to the tube, and ¼ inch in width; stamens shorter than the segments; style exceeding stamens, but shorter than the segments; stigma capitate; cup about ½ inch (or more) in length and width, 6-cleft nearly to the base; span of flowers, 5 inches; span of umbel, 9 inches.

This is a stove plant, and requires minimum warmth of about 70° to open its flowers perfectly; even then, many flowers have five segments and stamens, and some only four. It possesses the same fragrance as H. speciosa. *A. Worsley, Mandeville House, Isleworth.*

Obituary.

SIR HENRY BINNS.—Intelligence was received in London on Wednesday of the death of the Premier of Natal, Sir Henry Binns. The deceased gentleman was long and deeply interested in developing the natural resources of the colony he had so long since made his home. Horticulture and agriculture were much indebted to him; he early applied himself to Sugar-planting, and was one of the promoters of the first sugar-planting company established in the colony. Tea and coffee-culture received much attention from the departed Premier, who, in fact, thoroughly identified himself with the best interests of this old African colony. The late Premier was a native of Sunderland, and the life began in that busy northern town has continued a busy one until the close.

SOCIETIES.

ISLE OF WIGHT.

THE monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. Dr. J. GROVES, B.A., J.P., presided over a good attendance of members.

An excellent paper, by Mr. Jno. Hygate, of Cowes, on the "Cultivation of Dahlias," evoked an interesting and profitable discussion. A bee-keeping sub-committee was elected to consider the best means of developing this industry in the Garden Isle.

Forty-nine new members were elected, which brings the total number on the books to about 400. On Thursday, June 1, a large number of members availed themselves of an excursion to London to visit the Temple Show. *S. H.*

SHIRLEY GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.

MAY 29.—At the monthy meeting of the Winchester Gardeners' Mutual Improvement Association, which was held on the above date, Mr. Harry Curtis, Gardener to W. F. G. Spranger, Esq., J.P., Southampton, gave an interesting lecture on "Some Hardy Garden Flowers." The chair was occupied by A. Munro, Esq., and there was a good attendance.

Cultural directions followed for each plant named, making the lecture of value to young gardeners and others just now thinking of preparing for next spring's display.

A very fine display of hardy cut flowers was made by Mr. Curtis.

CHEMICAL MANURES FOR POT PLANTS.

THE practice that had been pursued for at least two centuries of including rotted manures in potting composts, and when these were exhausted, rendering aid to the plant by means of repeated applications to the soil, of diluted manure-water, continued till about thirty years ago, almost the only method of feeding pot-plants. Previous, however, to that time, the discovery of guano placed at the disposal of the plantsman an easily soluble manure, which, it must be said, he was not slow to avail himself of. By degrees the unquestioning belief that crude animal-manures were alone efficient, has been slowly but surely undermined, and while recognising their value as aids to cultivation, not a few cultivators deprecate their exclusive employment, and rely now very largely on chemical manures as equivalents that are, while more cleanly to use, capable of being employed with an effect almost unerring in its certainty. But when one in some degree realises the extent to which artificials now enter into the economy of high-class farming, we cannot but assume their use in horticulture to be as yet in its infancy, though no doubt the infant is marked by the possession of not a little vigour, and exhibits a tendency to shoot up rapidly; while, if we judge from the number of proprietary foods already in the market, no fear need be experienced that the child will suffer from want of nourishment.

That this subject may be treated of briefly, and yet in a manner intelligible to the many who have bestowed upon it only a cursory attention, it is, I think, not at all requisite to plunge into text-book details as to plant requirements, and the means of meeting them. Better, perhaps, to emphasise some few points, the practical importance of which cannot be overlooked. And, first of all, we may dispose of proprietary manures, all of which are naturally expensive to purchase, and judging of the value of materials, we cannot help thinking they are dear at the money. Farmers' clubs protect their members both as to price-values and quality of materials. The gardener has no protection beyond the honesty of the vendor. Some compositions, if expensive, are, however, made up of reliable constituents, and in such cases the difference in price where only a few hundredweights are used annually is really of slight importance. The case, however, stands on a different footing when slaughter-house refuse, cleanings of pigeon-cotes, or the remains of worn-out hacks, are worked up into manures, and sold at high figures. I have had examples of these through my hands that were distinctly dangerous to plants to apply. The use of an efficient general manure, composed of chemical component parts, is, on the other hand, rather to be approved than too lightly condemned. They are especially useful for mixing with composts, and it is mainly for this reason that I appreciate certain mixtures.

Turning to simple chemical materials available for plant foods, it is, I venture to say, unnecessary to employ many. Prepared composts, which have fibrous turf as a base, are always more or less fertile, and when dry animal excrements enter into their composition, they are rendered still more fertile, and experience shows the additional food required to be of a very simple nature. The writer lately examined several long glass structures filled with show Pelargoniums, with the flower trusses in various stages of development, some fully expanded, others yet in the bud. They were all good stuff, such as any gardener would have been proud to produce, yet their rooting medium was confined to the soil in pots 4 inches in diameter. The compost employed was loam and horse-droppings, and the only manurial help the plants had received were occasional dressings of nitrate of soda. I have myself applied lime-water to certain plants, and have also used as a surface-dressing sulphate of iron, but the results were, so far as could be seen, nil. Potash in its various forms I have dispensed with years ago, and the only materials I find it necessary to apply, are nitrates and phosphates. Of the former, I personally prefer sulphate of ammonia to nitrate of soda. A good superphosphate for some things, or slag flour, supplies the latter; but the almost perfect feeding qualities possessed by properly constituted composts, should never be lost sight of. *R. P. B.*

(To be continued.)

An Unfounded Report.—A report having been circulated that Mr. Maycock was leaving Luton Hoo Gardens, Major S. John Taylor, acting for Lady de Falbe, begs to inform us that there is not at present, nor likely to occur, a vacancy for Head-gardener at Luton Hoo. *June* 3.

[The term "accumulated temperature indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. *Principal Wheat-producing Districts*—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. *Principal Grazing, &c., Districts*—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending June 3, is furnished from the Meteorological Office:—

"The *weather* during this week was extremely fine and bright over the greater part of the Kingdom, but slight rain was experienced late in the week in most parts of Scotland, accompanied by thunder at a few of the extreme northern stations.

"The *temperature*, which was very low at the commencement of the period, subsequently rose quickly and became high, so that the average values for the week exceeded the mean in all districts except 'England, E.,' and the 'Midland Counties.' The highest of the maxima were registered, as a rule, either on Thursday or Friday; they ranged from 83° in 'England, S. (in London), to 73° in 'Ireland, S.,' and to 72° in 'Scotland,' W.' The lowest of the minima occurred on May 28, when the sheltered thermometer fell to 29° in 'Scotland, E.,' 30° in the 'Midland Counties,' 31° in 'England, N.W.,' and to 32° over 'England, N.E., E., and S.W.,' and also in 'Scotland, N.' Elsewhere, the lowest readings ranged from 33° in 'Ireland, N., to 41° in the 'Channel Islands.' The extreme range of temperature during this week was thus unusually large, amounting to 48° at Loughborough, and to more than 40° at nearly all the other inland English stations, as well as at Fort Augustus.

"*Rainfall.*—Slight rain occurred in Scotland and extreme 'Ireland, N.,' during the latter part of the week, but with this exception the week was quite rainless.

"The *bright sunshine* was extremely abundant, especially over England. The percentage of the possible duration ranged from 88 in the 'Channel Islands,' 85 in 'England, S. and S.W.,' and 83 in 'England, E.,' to 67 in 'Ireland, S., 54 in Scotland, E.,' and to 35 in 'Scotland, N.' The highest percentages recorded at any individual stations, were 90 at Watergate (Emsworth), 89 at Jersey, and 88 at several southern and south-western coast stations."

MARKETS.

COVENT GARDEN, JUNE 8.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Potatos.

Bruce, Main Crop, Up-to-Date, &c., 40*s.* to 80*s.*; Dunbar Main Crop, 100*s.* Jersey new, 8*s.* to 9*s.* per cwt; Canary, 10*s.* to 13*s.*; Cherbourg and St. Malo, 7*s.* to 7*s.* 6*d.*; Lisbon, per box, 3*s.* 6*d.* to 4*s.* *John Bath, 32 and 34, Wellington Street, Covent Garden.*

Remarks.—Old Potatos in little request, only a few of the best commanding a sale. New Jersey Potatos are coming in fast. Asparagus plentiful in supply, and low in price. Cauliflowers, both foreign and English, also Turnips, are now coming.

FRUIT AND VEGETABLES.

Glasgow: *June* 7.—The following are the averages of the prices recorded since our last report:—Oranges, 6*d.* to 1*s.* per dozen; Grapes, home, 2*s.* to 4*s.* 6*d.* per lb.; do. foreign, 6*d.* do.; Tomatos, Guernsey, 4*d.* to 8*d.* per lb.; do., Scotch, 5*d.* to 8*d.* do.; Cabbages, Spring, 7*d.* to 9*d.* per dozen; Cauliflowers, Edinburgh, 2*s.* 6*d.* do.; Herbs, assorted, 1*d.* to 2*d.* per bunch; Mint, green, 6*d.* do.; Onions, 4*s.* 6*d.* to 5*s.* per cwt.; Parsley, 2*s.* per stone; Carrots, round, new, 1*s.* per bunch, and 6*s.* per cwt.; Cucumbers, 4*d.* to 5*d.* each; Lettuces, round, 1*s.* 3*d.* to 1*s.* 6*d.* per dozen; do., Cos, 4*s.* to 5*s.* dozen; Radishes, long, English, 1*s.* 6*d.* per dozen bunches; Horseradish, 1*s.* 6*d.* to 2*s.* per bundle; Mushrooms, 1*s.* to 1*s.* 2*d.* per lb.; Beetroots, 6*d.* to 7*d.* per dozen; Mustard and Cress, 3*d.* per punnet; Spinach, 2*s.* to 4*s.* per stone; Rhubarb, 2*s.* 6*d.* to 3*s.* 6*d.* per cwt.; Broccoli, Irish, 2*s.* to 2*s.* 6*d.* per dozen; Turnips, French, white, 1*s.* to 1*s.* 3*d.* per bunch.

Liverpool: *June* 7. — *Wholesale Vegetable Market.* — Potatos, per cwt., Jersey, 8*s.* to 9*s.*; Main Crop, 3*s.* 4*d.* to 3*s.* 9*d.*; Bruce, 2*s.* 8*d.* to 3*s.* 4*d.*; Parsley, 6*d.* to 8*d.* per dozen bunches; Onions, foreign, 4*s.* to 5*s.* per cwt.; Lettuces, 6*d.* to 10*d.* per dozen; Cucumbers, 1*s.* 3*d.* to 3*s.* per dozen; Cauliflowers, 1*s.* to 2*s.* 3*d.* do.; Cabbages, 6*d.* to 1*s.* do. *St. John's.*—Potatos, 1*s.* to 1*s.* 4*d.* per peck; do., new, 2*d.* to 6*d.* per lb.; Grapes, home, 2*s.* to 3*s.* do.; Pines, English, 4*s.* to 6*s.* each; Strawberries, 6*d.* to 5*s.* per lb.; Gooseberries, 3*d.* to 4*d.* per lb.; Peas, 4*d.* per lb.; Cherries, 6*d.* to 1*s.* per lb.; Cob Nuts, 6*d.* to 8*d.* do.; Apricots, 1*s.* per dozen; Asparagus, 2*s.* to 4*s.* per 100; do., 1*s.* 6*d.* to 3*s.* per bundle; Cucumbers, 3*d.* to 4*d.* each; Mushrooms, 1*s.* 2*d.* per pound and basket. *Birkenhead.*—Potatos, 1*s.* to 1*s.* 2*d.* per peck; do., new, 1*d.* to 2*d.* per lb.; Peas, 4*d.* to 6*d.* do.; Asparagus, 1*s.* 6*d.* to 3*s.* per 100; Cucumbers, 2*d.* to 6*d.* each Strawberries, 8*d.* to 1*s.* per lb.; Cherries, 8*d.* to 10*d.* do. Apricots, 1*s.* per dozen; Gooseberries, 4*d.* per lb.; Grapes home, 3*s.* to 4*s.* do.; Mushrooms, 1*s.* to 1*s.* 4*d.* do.

SEEDS.

London: *June* 7.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report a thin attendance on to-day's seed market, with but few transactions passing. Clover seed is now naturally quite a dead letter. For Alsyke Clover there is some little speculative inquiry Spring Tares meet a good sale, but supplies are very nearly exhausted. Full prices are asked for Mustard and Rapeseed. Canary seed is strong at the recent interesting advance; holders in view of the universally bad crop prospects, and a further consequent rise in values expected thereon, refuse to let go their stocks, which, by the way, prove quite moderate, at the present, still comparatively low rates ruling. Hempseed continues scarce and dear. The Linseed market is steady. There is no change this week in either Peas or Haricot Beans.

CORN.

Average Prices of British Corn (per imperial qr.), for the week ending June 3, and for the corresponding period of 1898, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1898.		1899.		Difference.

Wheat	46	3	25	4	− 20	11
Barley	26	10	24	4	− 2	6
Oats	21	0	18	1	− 2	11

Answers to Correspondents

A Stiff Clay Soil: *H. C. B.* Digging or ploughing the land, and then using the subsoil plough for loosening the soil below the depth reached by the first ploughing or digging; or trenching two spits deep, but leaving the top spit for two or three years at the surface, would ameliorate its condition considerably. But it will also require manuring, and be deficient probably in humus; the decayed organic remains of vegetation which, when exposed to the air, affords a variety of plant foods. It will suffice the first year to plough or dig in quick-lime, strawy manure, fine coal-ashes, sand, garden rubbish—anything, indeed, that will maintain the soil in a porous condition, and on decaying provide food for plants. It would be advisable to have average samples, or sample, of the soil analysed, so as to obtain a knowledge of its composition, and the manures most required. A dressing of sulphate of ammonia 200 lb., dissolved bone-black 1000 lb., muriate of potash about 300 lb. and bone-meal 1 cwt., may be applied per acre, as a top-dressing, and hoed into the soil. This will in no case be a waste of money. As the annual digging or ploughing is carried out, a little of the subsoil may be brought to the surface. Hitherto, the manures you have applied have been of little avail, owing to the impervious state of the subsoil.

Books: *H. A. Davidson. The Handy Book of Bees*, by A. Pettigrew (Blackwood & Sons, Edinburgh and London). There have been several editions of this useful manual. Another good one is Mr. T. W. Cowan's *Bees and their Management*, published by Houlston & Sons, Paternoster Square, London, E.C.—*T. H. W. I.* There is no work known to us that treats only of the propagation of forest trees. This kind of information is usually embodied in works on Forestry, such, for example, as those of Jas. Brown, Dr. Schlick, J. C. Brown, C. Y. Michie, A. D. Webster, and Brown and Nisbet.

Celosia Diseased: *N. H. P.* The cause of trouble is a fungus, but the supply of material and its condition on arrival render exact identification hazardous. Try the usual measures against greenhouse fungi—more air, less moisture. Also keep the foliage fairly dry by not wetting it every time the plants are watered. Spraying with a fungicide would be beneficial, but we cannot give exact details, because as yet we have not seen results of reliable experiments. In any case, with such delicate foliage as this plant has, only very dilute solutions can be used—say potassium sulphide one-third of an ounce to each gallon of water, or a weak Bordeaux Mixture.

Correction: **Temple Show.**—Owing to a typographical error Messrs. Sutton & Son's baskets of Peas were given as being four in number, instead of forty. *Re* Cactus-flowered Pelargonium, fig. 128, of the issue of June 3, the exhibitor's name should have been Towell, not Powell; and that of the exhibitors' of Astilbes should have been Gt. Van Waveren and Kruijff, instead of M. Van Waveren.

Cucumber Plants going off at the Ground-level: *Key.* There is no disease, but the stems have become woody in appearance, and no eelworms existed on the roots. We should attribute the mishap to the use of chemical or very strong farmyard or other manures applied to the soil close to or touching the stems of the plants.

Cucumber-culture: *Market.* We would rather recommend fish-manure, or a so-called guano, or superphosphate of lime, in preference to nitrate of soda; and it would be wise to change the kind of manure from time to time. House-sewage, well diluted; soapsuds, or horse, cow, and sheep's-dung, put into a cask, and allowed to ferment for a time, form good aids to Cucumber cultivation, and they have the merit of costing but little.

Diseased Leaf of an Orchid: *W. J. K.* Although there may be fungoid growth on the leaves of the Dendrobium sent, the appearance mon in Orchids grown in an unsuitable ature, or kept continually in much heat. he new growths are completed, afford the a long rest in a cool, airy house, keeping them dry, and probably theleav es will come right next season.

Gumming in Cucumbers: *Market.*—It may be due to the presence of eel-worms at the root. Can you kindly send some pieces of the roots and gummed-fruits?

Mangold Wurzel Seed: *W. T. J.* Late in the autumn when the roots are of full size, select the finest of the variety of which seed is desired, and having taken them up intact, cut off the leaves about 4 inches from the root; then store them in a bank of sandy soil, the tops outwards, so leaving them till the spring, but taking care that the frost does not injure them. A cool cellar or root-store on the N. side of a wall are suitable places. When the roots are planted in the end of March, select an open situation sheltered from the wind, planting the roots 2 feet apart, and not deeper in the soil than they grew the previous year; make the soil firm round about them, and afford water once if the soil be dry at time of planting. If a plant throws a great number of flower-shoots, some small amount of thinning-out may be desirable; and when the flower-stalks are 1½ foot high, they should be secured to stout sticks, 5 feet high at the least; and be secured with other ties as they continue to lengthen. The seed-bearing stalks, when it is seen that the seed is fully matured, should be cut low down, and be hung in bunches of half-a-dozen in a dry shed, to be thrashed out and cleaned in the winter months. If more than one variety is saved, the plants should be placed half a mile apart, and it would be well for the cultivator to ascertain if any of his neighbours are saving seed, and act accordingly.

Manures for Fruit-trees: *H. C. B.* We give the following recipes taken from W. Semper's *Manures, and How to Use them.* To make 1000 lb.: take nitrate of soda 250 lb., ground bones 200 lb., bone black superphosphate 250 lb., muriate of potash 300 lb. Apply 500 lb. per acre. Another, ground bones, 300 lb.; bone black super-phosphate, 300 lb.; muriate of potash, 400 lb.; apply 350 lb. per acre. Per acre for all kinds of fruit-trees:—Sulphate of ammonia, 50 lb.; sulphate of magnesia, 25 lb.; muriate of potash, 100 lb.; Dissolved bone-black, 425 lb.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—R. D.* 1, Pyrus torminalis; 2, P. Aria.—*B. N. C.* 1, Mespilus germanica; 2, Saxifraga granulata, double-flowered: thanks for the buttonhole!—*W. T.* Scilla peruviana.—*H. A. B.* 1, Hyacinthus comosus; 2, Pernettya mucronata.—*J. K.* Cytisus Adami, a supposed graft hybrid between C. Laburnum and C. purpureus.—*G. M. K.* Quercus cerris, the Turkey Oak.—*F. K.* 1, Probably Dendrobium fimbriatum; 3, Dendrobium aggregatum; 6, Nephrolepis tuberosa; 7, Anthurium Scherzerianum. The two Begonias and Caladium had lost their colour; they are garden forms, difficult to name even from good specimens.—*R. N. H.* Maxillaria tenuifolia.—*A.* 1, Dendrobium Parishi; 2 and 3, Dendrobium Bensoniæ.—*M. R.* 1, Cratægus coccinea; 2, next week; 3, Scilla peruviana; 4, Lychnis dioica, double-flowered; 5, Anthericum liliastrum; 6, Veronica Teucrium.

Pelargoniums Diseased: *A. S. W.* That a fungus has established itself in the cuttings is evident. Cuttings of any kind are liable to attack by fungi unless carefully handled. The fact that your worst batch travelled and got "heated," points to that time as the period of attack. Any living parts of plants packed for transit are liable to develop moulds or other fungi on the way; we constantly find this with plants sent here for advice. If cuttings are left unplanted for any time, it is always a good precaution to remove about half-an-inch of the cut-end with a clean sharp knife before planting. In order to avoid infection from the soil, it should be clean, fresh, well-drained, and not previously used for striking cuttings. The well-known loss of Pelargonium cuttings when kept too moist, is chiefly due to fungi. In the present case, nothing can be done to save the plants badly diseased; the better ones might benefit by repotting.

Rose: *H. P.* We cannot undertake to name varieties of Roses. Take it to some extensive grower of these plants.

Roses: *W. B.* You are correct in supposing the pest to be known as Orange-fungus, and seldom have we seen a better specimen. As this fungus is one of those that vegetate in the leaves and stems of its host, the cultivator's chance of wholly ridding his trees of the pest is not a good one. At the present date of the season, all you can do is to try and destroy every bit of Orange-fungus (now fruiting) possible, by spraying with Bordeaux Mixture or other fungicides. If the plants are badly infested, it will be well during winter to give the soil a good dressing with quick-lime, with a view to killing the resting-spores; and for the same purpose, the Rose-plants may be painted with a mixture of quick-lime and soot, mixed to the consistency of paint, in a pailful of which add half-a-pound of sublimated sulphur and a small handful of coarse salt. When pruning the trees, take care that all shoots that are cut off are burned directly afterwards. This fungus was figured and described with much detail in the *Gardeners' Chronicle*, July 17, 1886, pp. 76, 77.

Spiræas Diseased: *A. S. W.* The foliage is attacked by a form of Botrytis, a group of fungi causing well-known diseases on Tulip, Onion, Lily, and Clover. The disease is not uncommon when Spiræas are kept indoors in a moist atmosphere. We have checked it by simply placing the plants out of doors. To prevent its appearance in the house, the plants should be sprayed before the leaves unfold, and onwards every two or three weeks till near flowering time. Almost any spraying mixture will do, such as soapy-water, or sulphur in water; better still, Bordeaux Mixture, potassium sulphide, or Strawsonite.

Tomatos Diseased: *H. S.* Another case of the obscure "sleepy disease." See reply to "C. J.," in a recent issue. You have, however, dropped a very valuable hint in treatment in saying, "the seedlings left in the seed-pots remain healthy, while those repotted decay off within a week or ten days." The suggestion here is self-evident.

To render a sticky, hard Soil Friable: *Puzzled.* Let the following substances be incorporated with the staple whenever there is occasion to dig it: Fine coal-ashes (the siftings of the ash-pit), road grit (scrapings), the trimmings of the roadsides if you are living in the rural districts, rough peat, ditch scourings, fine ballast (burnt clay), quick-lime at the winter digging, coarse garden rubbish put into the bottom of the trenches when the land is double-dug, and not disturbing it for three years. The land will in time get much altered in texture. Never let the hard crust that forms after rain, &c., remain intact, but break it up with the hoe.

Watering a Suburban Garden: *Puzzled.* The better time is the evening, when evaporation is the least; and although the water from the main is comparatively cold, its temperature is raised in its passage through the sun-heated soil, and no harm is done. If an application of water be thorough, as it should be, and not a mere dribble, once a week, even in sunny weather, will suffice. Always stir the soil with a Dutch-hoe, or a hand-fork, a day or two after affording water, so as the better to allow air to enter the soil and reach the roots. Of course, if the soil is light or gravelly, much watering impoverishes it rapidly, and something ought to be done to furnish plant-food thus carried to lower depths than the roots of flowering plants reach to. This may be done by affording occasionally liquid-manure, or dressing of nitrate of soda, kainit as meal, potash, &c.

THE
Gardeners' Chronicle
No. 651.—*SATURDAY, JUNE* 17, 1899.

MENTMORE.

THE domain of Mentmore strikes the beholder as being magnificent on a still June evening as he passes through it from the railway station at Cheddington. This little station is of importance as being the point whence starts the branch line to Aylesbury, not far away; and as one travels by this branch a fine view is obtained of Mentmore and its park, while a glimpse can be caught of Waddesdon on the western hill. On leaving the village by road the visitor passes through many acres of fruit-orchards, mainly planted with Plums, the Prune variety largely preponderating, fringed here and there with lines of Walnut-trees, flushed with the bronzy-red of their early foliage. Then comes the avenue of Sequoia gigantea, shortly called the Wellingtonia Avenue, wherein it is seen the examples were planted in threes, in the form of a triangle, their sharp formal outlines standing out in marked contrasts with the noble clumps of evergreen and deciduous tree and shrub which alternate, and which were planned and planted by the late Mr. James Veitch. One could almost desire, for the sake of more striking effect and harmony, the English Oak, which appears to do well on the Mentmore estate, had taken the place of the Californian trees, some of which appear to be scarcely happy.

Then follows the Horse-Chestnut Avenue, the specimens forming which are now approaching maturity: there are two lines of trees on either side, each at an equal distance apart from its fellow; they are now generally in glorious bloom, and show seminal differences in the shape of outline, in the time of flowering, in the size of the spikes of bloom, in their floriferousness, in the differences of habit. But they are all doing well, and twenty years hence, when in all probability they will have matured, it will, indeed, be a noble avenue; and this is a public road, along which anyone can walk or drive, kept in excellent condition by Mr. Smith at the expense of Lord Rosebery, whose property lines each side of it.

On emerging from the Chestnut Avenue, the home grounds of Mentmore are reached. It is in them one catches the mighty inspirations of the open air and green fields, of tree and valley, as the details of the landscape alternate by the way. The early evening is, perhaps, the best time at which to see Mentmore in all its beauty, when the softening sunlight falls over the land. What a change from London's city, with its bustle and struggle of commercial life, to the cool lawn and shrubberies, the shady roadway and singing birds. "The sunlight poured its unclouded beauty on every subject that one could see. The exquisite freshness of the air made the mere act of living and breathing a luxury." And then the leading features of the place—the palatial mansion; its appropriate surroundings; the broad, sweeping approaches to it; and the perfectly-kept grounds—all imparted to the scene a sense of enchantment. Mr. Smith, who has had charge of Mentmore over twenty years, can look upon many subjects he planted quite young that have meanwhile grown into stately specimens, and improvements which have greatly enhanced the beauty and the value of the estate. Planting-out is being done on the terraces to secure late summer and autumn displays. Nesfield's Italian garden, as good an example of this style as can be found in the country, will soon be furnished. Among flowering shrubs, the Persian Lilacs are superb; and hybrid Rhododendrons in large clumps are gay with vari-coloured blossoms. Those who wish to see magnificent specimens of Conifers will find them at Mentmore; there are delightful Rose-gardens, and at every point something to arrest attention and delight the eye. What order everywhere! and yet the keeping of Mentmore must involve an immense amount of labour.

In the short time I could remain, an inspection of the houses in detail was impossible. A hurried walk through the vineries enabled one to note great promise. In the Pine-pits were splendid fruits. Plant-houses were gay; the London demand necessitates great supplies. The kitchen garden has been extended, and it occupies a great extent of slope, falling away towards Cheddington station.

A large extent of new buildings is being erected, new bothies, &c., with modern conveniences, stables, &c.; the bricks and other materials manufactured on the estate.

And then the picturesque village, not surrounding the estate, as Downing said it should, but within easy reach of the mansion, and surrounded by the grounds. It has a well-to-do aspect; there are no slums to be found here, but roomy cottages standing in pleasant gardens. The drive from Mentmore to Leighton was delightful, taken in the cool of the evening, just as the great red sun was setting in the fiery west, along roads overarched by the green foliage of the trees, almost to the confines of the Bedfordshire town. *R. D.*

NEW OR NOTEWORTHY PLANTS.

PYRUS THIANSCHANICA.

THIS new Pyrus belongs to the Aucuparia (or Mountain Ash) group, and judging by specimens from Mr. Smith's nursery at Newry, where the species has lately flowered, it promises to be a charming acquisition. There are specimens in the Kew herbarium collected by Przewalski in 1872, but the plant itself appears to have reached cultivation by way of the St. Petersburg Botanic Garden about ten years ago. It is described as a shrub or low tree, from 9 feet to 20 feet high, and the young plants in cultivation in this country promise to be dwarf and compact in habit. Like its allies, the Mountain Ash and the Service Tree, it has pinnate leaves; they consist of nine to seventeen leaflets, which are 1¼ inch to 2 inches long, perfectly glabrous, dark and rather glossy green, linear-oblong and toothed. The flowers in Mr. Smith's specimens are in terminal corymbose racemes, 3 inches to 4 inches across, the individual flower ½ inch to ¾ inch in diameter, with five round, cupped petals of the purest white. The calyx is small and green, its broad shallow lobes having usually a short mucronate tip. The fruits are in corymbose clusters, each one being round and about ¼ inch across. The species has been cultivated at Kew and elsewhere for some years past, but the flowers from Newry are the first I have seen. Possibly it may, like the Mountain Ash, be beautiful as a fruiting tree, but for its flowers alone it is evidently well worth growing. The Thianschan Mountains, from which this plant derives its name, are on the north-west confines of the Chinese Empire.

RHODODENDRON DECORUM.

The flowering of yet another of the new Chinese Rhododendrons has to be recorded. During the first week of June this species opened its flowers for the first time at Kew, and, so far as I am aware, in Europe. The Kew plants were obtained from the Jardin des Plantes at Paris in 1889, which establishment was, no doubt, indebted for them to the Abbé Delavay, who originally found the species in Yunnan. It is very closely allied to R. Fortunei, so closely, indeed, that it can scarcely be more than a geographical form of that species. The flowers are the same in colour, fragrance, and size, and, what points to their affinity still more, is that both have seven segments to the corolla. The only differences at present noted are the much more glandular peduncles of R. Fortunei, and the larger and more distinctly-lobed calyx of R. decorum. The leaves of the latter are also thicker and more rigid than in Fortune's species. In habit and in hardiness it is inferior, and unlike several other Chinese species recently mentioned in these columns, it does not promise to be of much value in our gardens here. R. Fortunei has all its good qualities and others beside. Still, in view of the interest which now attaches to the flora of Western and Central China, it may be of interest to put its first flowering on record. *W. J. Bean.*

ORCHID NOTES AND GLEANINGS.

LÆLIA PURPURATA VAR. ANNIE LOUISE.

WITH regard to this plant, which received a First-class Certificate at the Temple Show, Thos. Statter, Esq., of Whitefield, Manchester, writes:—"I believe it was explained by Mr. Cypher at the Temple Show, who was the original owner, that the certificated plant of L. purpurata Annie Louise was the same variety as that shown by me as L. purpurata Statteriana. The question arises, what is this variety in future to be styled, as there are still two more portions of the original plant, one with Mr. Schofield, the exhibitor of the certificated plant referred to, and the other with Mrs. Briggs Bury, at Accrington? I hold that 'Statteriana' is the right name, because I exhibited my plant at Manchester Botanical Gardens in 1897 and 1898, and on a later date under that name; and I received a First-class Certificate at Manchester under that name, L. p. Statteriana."

We fear that there are many similar cases, although examination of the two plants referred to at the show failed to prove conclusively that they were the same, Mr. Statter's flower being smaller and not so finely developed as Mr. Schofield's. At the show, another complication arose from the suggestion that L. p. Mrs. R. I. Measures, an inflorescence of which was present for comparison, was also the same as L. p. Annie Louise, and certainly its well developed flowers seemed nearer than those of Mr. Statter's plant. All three might have been from the same stock (though Mr. Measures' plant was taken from an independent specimen), and cultivation has made the difference.

If purchasers would honestly retain the names under which plants were bought, and vendors would faithfully sell all the parts of the same specimen under the same name given, before the plants were distributed, such confusion would be materially diminished. We fear that complications of the kind are more often intentional than accidental. In the face of the present difficulty, it will be better to adhere to the name given at the Temple show.

ORCHIDS AT ELMWOOD.

J. Wilson Potter, Esq., an Orchid amateur resident at Croydon, has had much experience as an orchidist, and has tasted the delights of success in their culture, as also the reverse, when some species have been intractable. This intractability is generally due to the unsuitability of the houses, or to something in the methods of cultivation pursued. The proof that this is the case is afforded by the improvement in the collection since its removal to Mr. Potter's new residence, and especially since they have been under Mr. Young's care.

The old set of houses at Elmwood have been added to by the erection of a rather high, long, three-quarter-span range, fitted with appliances likely to benefit the plants grown in it. Rain-water tanks are provided, shading-blinds are carried well above the glass, and the moist evaporation from an unpaved floor helps to make cool, growing conditions even in very hot weather. The large number of Odontoglossum crispum, many of them as yet unflowered, promise well for the future. Among the O. Pescatorei is the certificated plant of O. P. Sligachan variety, which, after flowering so beautifully as it did when shown, became obstinate, and did not grow satisfactorily until lately, when it again made two leading bulbs. Odontoglossum Halli is well represented, one of the forms of it being the equal of the best known varieties; and many showy species of Odontoglossums are thriving, and all are showing a marked tendency to increase the number of their leading growths and maturing the pseudobulbs.

The Cattleyas are equally promising, even small plants having numbers of young growths disproportionate to their size, especially C. Percivaliana, a stout plant of which in a large 48-pot possessed nine of them, and others five or six. The Cattleyas and Lælias grow in a commodious span-roofed house, the space beneath the stages being furnished with rockeries, planted with Tradescantias, Begonias, and other low-growing plants; the path consisting of trellis-work laid on the natural earth. This method of construction has taken the fancy of many cultivators of Orchids, and they are adopting it largely in preference to cement, stone, &c. The appearance of the Cattleyas is quite satisfactory; all of them growing and flowering in their season. At the present time, the show consists principally of Cattleya Mossiæ in variety, including a nice plant of the white C. M. Reineckiana in bud, and a fine form of C. M. Wagneri; and others in bud or flower are Cattleya Schilleriana of a very fine type, C. Mendeli, C. Gaskelliana alba, C. Warscewiczii, Odontoglossum citrosmum, Epidendrum falcatum, and E. nemorale.

In a warm house, the showy Dendrobiums are thriving surprisingly, and especially some hundreds of Dendrobium Phalænopsis, every bit of which seems to make a strong plant in a short space of time. These and other species of Dendrobium are suspended near the roof. Lælia Digbyana and Diacrium (Epidendrum) bicornutum are plants not usually considered easy to manage, which here thrive remarkably, the Diacriums coming into flower regularly. A recently-imported plant of Lælia Digbyana is showing its flower-spike. Flowering plants of Cypripedium Lawrenceanum, C. Mastersianum, and a few others are in bloom.

A FLOWERING BAMBOO.

A PLANT of Bambusa vulgaris, the B. arundinacea of some authors, but not of Willdenow, according to Dr. Stapf, flowered at the Experimental Station and Nurseries, St. Clair, Trinidad. The illustration (fig. 137) shows a branch cut from a large clump and placed in the ground for the purpose of being photographed. During the past twelve years I have seen the Bamboo in flower on three occasions only, but have not yet seen perfect seeds. *J. H. Hart, Botanic Garden, Trinidad.*

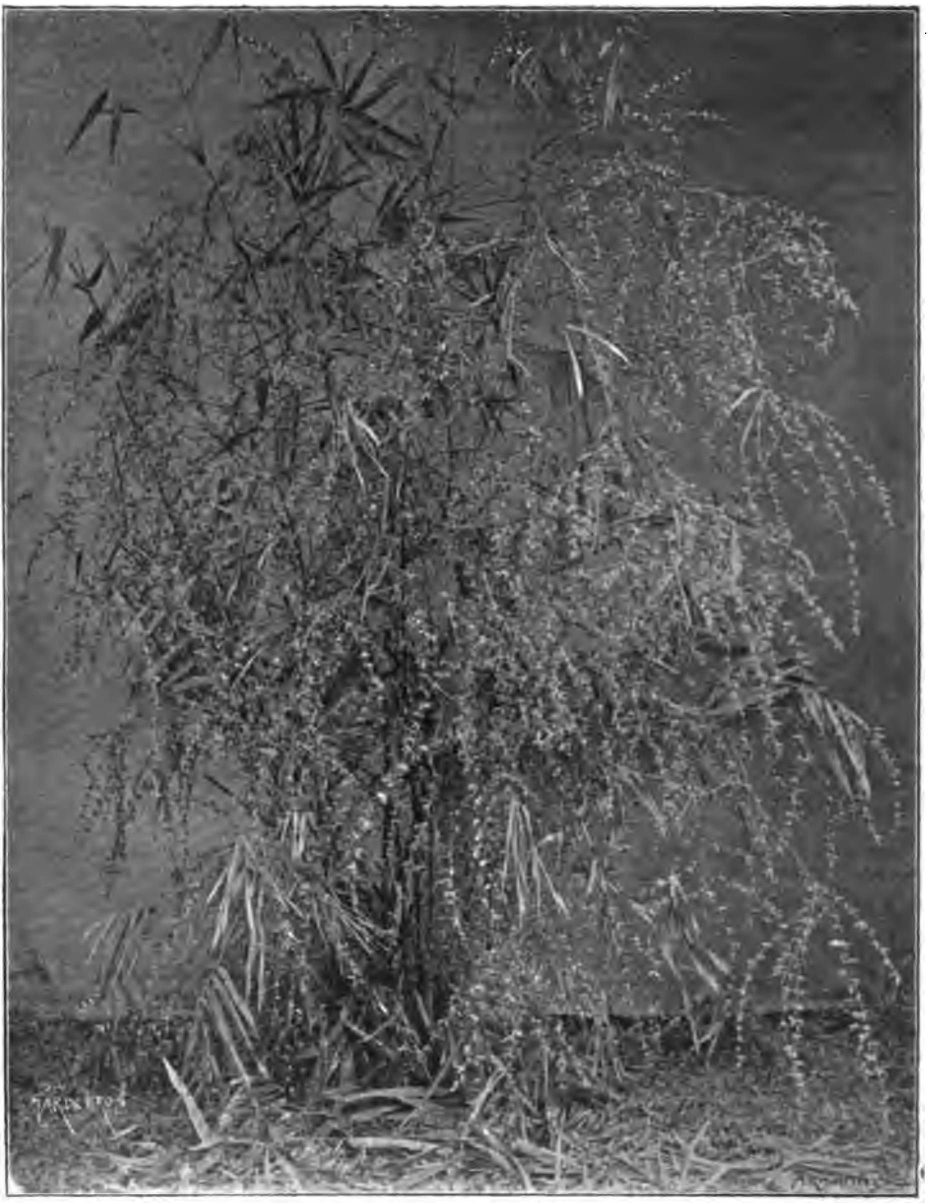

FIG. 137.—A FLOWERING BAMBOO.

CHEMICAL MANURES FOR POT PLANTS.

(Concluded from p. 387.)

THERE is, further, the varying natures of plants to be taken into account. A Strawberry, for instance, may require no food beyond that provided by the compost until the following spring, and even then two or three slight dressings of supers may be sufficient to produce high-class fruits. A Pelargonium, on the other hand, propagated in spring, and placed in its blooming-pot in June, will require occasional applications from the time it is housed in October right on till spring, and this in order that it may at no time approach exhaustion, but always be in a condition to produce flowers. The value of superphosphate in brightening colours is another point worthy consideration, and in no instance is this seen to better effect than in the case of plants with coloured foliage, of which Codiæums (Crotons) may be mentioned as an example. Not only will these plants colour better, but they may be also successfully grown for a long time in comparatively small pots, by the simple aid of the manures recommended; manure-water, to use a common phrase, is not in it in comparison. Another familiar class of plants that benefits to a surprising degree is various Palms. These may be preserved in vigorous health, and in that perfect, dark green condition of foliage which is so pleasing, simply by continued applications of superphosphate, though for these I prefer "slag flour;" and in order to produce larger fronds, free applications of nitrate of soda are also commendable.

Perhaps the most remarkable effect produced by the employment of superphosphates is that it exerts in the production of roots. Where pot-plants are lavishly supplied with water, this result is less apparent; but in my experience it has been invariably noticeable in cases where plants have been carefully watered. This fact, no doubt, explains how plants comparatively large in bulk can be successfully grown for many successive years on this food alone; and also how poor potting soils yield almost as good results when dressed with supers and nitrates from almost immediately after the plants have been potted. Composts mixed up with a larger than usual quantity of animal manures are no doubt, and possibly for the same reason, equally effective; but they are not lasting, and are always more liable to become soured through an overwatering. But it must not be expected that plants grown without repotting, even with all the aids of artificial manures, can be induced to make so good a growth as those treated regularly to fresh soil, or that poor composts by their use can be transformed into ones of equal value with those naturally of a high-class order. Their value though great is not supreme. It is worth noticing, too, that plants regularly dressed with "artificials" require a smaller quantity of water; or, to put it in another way, such plant may safely be left unwatered for a longer period than those which are not so fed. I by no means wish to insinuate soil-dryness as commendable in pot-culture, but no one can disapprove of a material that lessens the quantity of water, which may become a real agent of exhaustion, without in any degree affecting injuriously the health of the plant. As a matter of fact, a lavish application of water in conjunction with chemical-food, is a very real source of evil, as it causes a flabby growth, that however pleasant to look upon, is not seldom ruinous. This brings us to the important question as to quantities required, and methods of application. Generally an error is made in applying too much at a time, and renewing the dressing long before the previous one has been used up. A very slight dressing, often repeated is, therefore, to be preferred to one of larger quantities. It is a good rule to mix superphosphates and nitrate of soda, or sulphate of ammonia together, previous to using, and in the proportions of three of the former to two of the last named. When slag is employed it must be applied first, and the others not until a few days later. In the case of soft-wooded, rapidly-growing plants that can all be watered at the same time, the chemicals may be dissolved in the water and so applied. This, however, is a practice generally not to be commended. For one thing the manures, in the nature of the case, cannot be so evenly distributed, an extreme instance being that of a plant which at the moment requires no water, and therefore goes unfed. When, on the other hand, the manure is very thinly and evenly sprinkled over the surface of the soil, there is nothing left to chance that each plant receives its quota. If it requires water soon, so much is dissolved and carried through the soil; if longer, the material is still slowly dissolving, and in a more fit state for absorption. But in either case all fare alike. *R. P. Brotherston, Tyninghame.*

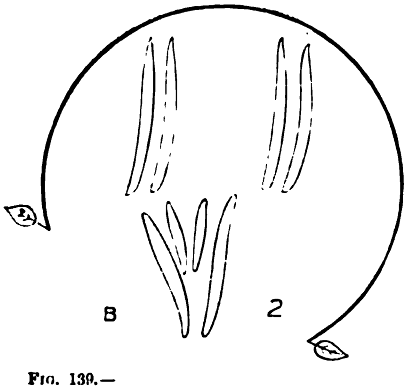

Fig. 139.—

B, Three sets of setæ. The two strong pairs from hinder part of worm's body; the set of four from anterior portion, showing characteristic form of setæ in this genus.

A PASTURE PROBLEM.

In 1895, Mr. J. Percy Moore, in some notes on American Enchytræids which appeared in the *Proceedings of the Academy of Natural Sciences* of Philadelphia, described a new species of white worm, under the name of Fridericia agricola. He made also the following statement relative thereto:—"These worms are slow and sluggish in movement, and rest most of the time coiled up more or less tightly. They are very plentiful in early spring about the lawns and meadows of Wayne, Delaware County, Pennsylvania, where they are found most frequently coiled up among the bulbous underground stems of Garlic. Later, during the summer, they become very scarce, apparently dying off, as almost none could be found on digging to a depth of 18 inches, and they did not reappear even when the ground was soaked by prolonged rains." In 1896 I found and figured this species in Cumberland; and in January, 1898, found it again by the river Eden, near Carlisle. In neither case was there any reason to suppose that the worm was injurious. I have now, however, to report it from Kent under circumstances which, to say the least, are suspicious. A short time ago (viz., during the Easter holidays), Mr. Charles Whitehead, of Barming House, Maidstone, sent me a consignment of small worms, with the following note:—

"I venture to send you specimens of a species of an Oligochaeta, evidently belonging to the Enchytræidæ. May I ask you if you can tell me what species it is? I find it in grass-land, which is suffering from some unknown cause. The grasses are dying off, and at the bases of the stems I find these Oligochaets. I am bound to say they are not very numerous, but as a rule there seems to be one at every diseased plant-base. May I ask you to tell me whether in your opinion this is sufficient to cause grass on fine soil to die off, so that the meadow looks unhealthy at a distance? It was supposed that the grasses are suffering from the water having been impregnated with gas-lime, but this would have killed the Oligochaets and other insects I found in the earth."

As the specimens supplied to me were preserved in spirits, I asked for living material to be sent, because the results to be obtained from the study of the animals in a fresh condition are always more satisfactory than when based on bottled specimens. A sod about 3 inches square, which arrived in due time, contained several living worms; and these were carefully examined with a view to the accurate determination of the species, as well as to ascertain if possible whether the worms had caused the mischief which seemed to lie at their door.

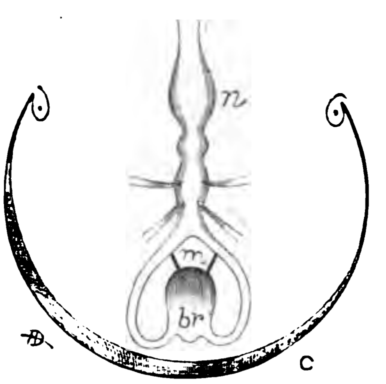

Fig. 140.—

C, Brain (*br*), or supra-œsophageal ganglion attached to nerve-chord, showing swellings (*n*) in early segments, and muscular attachments (*m*) by which the brain is fixed to the body-wall behind.

The species proved to be the same as that found by Moore in Philadelphia, and by myself in Cumberland (Fridericia agricola, Moore); and as it has never been fully described in any English journal, it seems desirable to give a pretty full account of the worm, with a few drawings, setting forth the main characteristics. There is a considerable variation in many particulars between one specimen and another, which largely depends on the age and development. I find them to be about 20 mm. or ¾ inch in length, and to consist of about 50 segments. Moore gives a length of 20 to 25 mm., and 65 segments for a mature worm. The setæ vary in number, from two to six. In some worms, only one pair of setæ is found in each bundle in the hinder half of the worm (fig. 139); but more frequently there are three or four, while five or six is the normal number in the front half. As with other species of Fridericia, the central setæ are always smaller than the outer, their proportionate sizes being represented by the camera lucida drawings appended herewith. "Sometimes the number is respectively five or three, owing to retention of one seta of the larger outer pair for a greater length of time than its fellow" (Moore). The discarded setæ seem to find their way into the coelom rather than fall outside the body, and they then appear more or less rubbed down or imperfect, as seen in the illustration (fig. 138). I find the head-

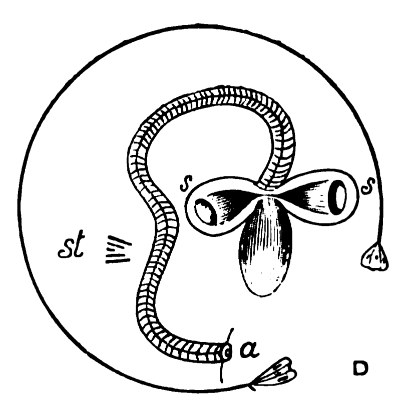

Fig. 141.—

D, Spermatheca from segment five, with aperture (*a*) between fourth and fifth segments. Shows two sacs (*s*) and a set of setæ in situ , drawn to the same scale.

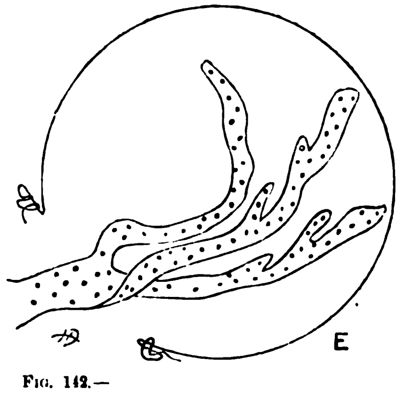

Fig. 142.—

E, Extremity of one of the salivary glands, or peptonephridia.

Drawn by the author from fresh material under the camera lucida.

pore between the prostomium and the first segment, and the dorsal pores commencing with the seventh segment, as Mr. Moore remarks.

Coming now to the study of the internal characters, we find the following distinguishing features. Moore says the brain, or supra-œsophageal ganglion, is like that of F. longa, Moore; two-thirds as broad as long, and convex behind. This agrees with my woodcut (fig. 140), but I may add that the front also has a prominent convexity. The nerve-chord also in the front segments shows some features which are characteristic. "The salivary glands are conspicuous, and each is divided into from five to seven slender tubular branches, which may themselves be simple, or provided with one or two lateral twigs. The tubes are of very irregular diameter. As Mr. Moore gives a figure of one of these glands, it may be compared with my own (fig. 142), taken from microscopic preparation with camera lucida. The same applies to the spermathecæ (fig. 141), which open between segments four and five, lying in the latter segment in contact with the intestine. "The long, slender stalks are from six to seven times the length of the sacculated portion. The enlarged portion consists of a central thick-walled cylindrical region, capped by a thinner-walled, more or less conical piece, which at its apex opens into the œsophageal lumen. A single pair of accessory sacs arise opposite to each other from the base of the thick-walled region." In one specimen from Kent the sacs were triple, in this respect allying the worm to F. ulmicola, Friend. "These sacs," Mr. Moore continues, "are of subspherical, or sometimes more or less flattened shape [depending on age and development], and when fully developed, quite as large as the primary sac. No glands are present at the mouth of the spermatheca." This is a point of great importance for purposes of diagnosis. Mr. Moore says nothing of the septal glands. I find these to consist of three pairs, lying in segments four, six, and seven, the sacs of the spermathecæ being in segment five. I have not yet studied the nephridia, but Moore says "the anteseptal portion is ovate, the post-septal slender, with a dorsal lobe about equalling in size the anteseptal. The terminal duct passes forward nearly to the septum, and then bends sharply backwards to its external pore." I have studied the blood-vessels of the first four segments, as it seems to me that a little more attention needs to be paid to this characteristic. I find that the prostomium sometimes tends to become papillose. In the adult worm no setæ appear on segment twelve where the girdle is situated. A pair of large pores occur here, from which protrude hyaline sacs. The girdle usually extends into the thirteenth segment. I have not observed the segment in which the dorsal vessel originates.

The question now arises, is Fridericia agricola, Moore, injurious to grass and cultivated plants? I am bound to say that when I found it in Cumberland, there was not the slightest ground for suspicion. In the one case it was discovered at a roadside drinking-trough, where the water from upland pastures trickled over moss and grass. In the other case, it was just under the crown of the soil in grass by the water-side, and was, in my opinion, living on vegetable *débris*, and not on the living grass. I have enquired of Mr. Whitehead whether the meadow was low-lying, and find it is so. I should say the worms are not hastily to be condemned; though they were found in the stems of grasses, they may have been there as scavengers, because the grass was already injured. A wide field of inquiry is opened up, and as I have for some years been making a special study of the white worms in relation to agriculture, floriculture, and horticulture, I propose to give some account, in some further articles, of white worms found in the manure used for gardens and pastures. Meanwhile, I shall be glad to hear of any facts which tend to throw light on a subject which is of the highest importance in its bearing on the future of agriculture. *Hilderic Friend, Ocker Hill, Tipton.*

DESTRUCTIVE FUNGI.

A Willow-Destroying Fungus (Cryptomyces aureus, Mass.).—A visit to the Norfolk Broads when the ground is covered by snow all over the rest of the country, is not perhaps an ideal way of taking a holiday, but certain fungi have to be obtained during the winter if one wants them to germinate to the best advantage. On the banks of a stream running into one of the Broads a number of stunted Willows were observed. On examination it was found that their stunted growth was due to this parasite, which, at the time of observation, was in full vigour, for evidently this is a fungus which fructifies at all seasons of the year. It was originally figured by Sowerby in his *English Fungi*, t. 356, under the name of Sphæria aurea. It first appears on the young twigs, upon which the shining black patches are surrounded by a very marked bright yellow border that contrasts strikingly with the smooth green bark. On rather older twigs the yellow circumferential zones are not so distinct, while upon older branches still they are practically not observable. After a time the shining outer stroma covering the young spots ruptures, and the sporidia escape very much after the style of the Rhytismæ. The patches of disease extend in a centrifugal manner, so that the branches denuded of their bark, with the outer segment of the woody tissues dead and blackened by the fungus, present a very deplorable appearance. The affected branches die after a time, hence the blighted and stunted look of the affected shrubs. *C. B. P.*

An Elm-tree Parasite, Polyporus Ulmarius, *Fr.*

This is a fungus the sporophores of which are not found every day, probably because they are not looked for in the right place. Unlike most Polypori the pilei are formed inside the tree, not outside, hence it is useless to look for them excepting in hollow trees. It has long been known as a British fungus. Sowerby figured it in his *English Fungi*, t. 88, in 1797. Mr. Berkeley in the *Outlines* says it is found "in old Elm trees," and that it is common. His figure, plate 16, fig. 5, is a very poor one, for instead of the pileus being blackish, as he represents, it is whitish. The margin is always white, and the tubes yellowish or orange, not alternately red and white, as his figure shows them. In reality, it seldom forms a pileus at all—at least, not a pileus with a free edge. The specimen on this page (fig. 143) was gathered from the interior of a huge Elm, overturned by the wind, which grew at Ashwicken Hall near King's Lynn. There were about a dozen specimens, only one of which had formed a dimidiate pileus; the others were effused. The total number would never have been suspected had not the hollow stump been large enough to crawl into. They were then seen affixed not only to the sides, but adhering to the roof of the tunnels, which represented the main roots. As a matter of fact, we must regard Polyporus ulmarius as an Elm-hollowing parasite. It is unlike P. fraxineus, for when this fungus once attacks a living Ash, the tree is doomed, and seldom lives, according to my experience, more than a year or two; but with P. ulmarius the case is different, the affected trees become hollow but continue to live for years. Both species are found most frequently upon the base of the trunks. A section of P. ulmarius shows that it is perennial. The yellow-brown tubes contrast with the white flesh, so that it is easy to see the manner in which the sporophores have been developed. How they are superimposed one upon another, and that not only so, but that the earlier are included in the later. The point which interests us is that it is essentially for its manner of growth, a tree-hollowing fungus, and that it is a true parasite. The question of "tree hollowing" is one which has not received the attention it deserves. Hartig has shown how P. annosus (Trametes radiciperda) causes piping in Larch-trees by the mycelium creeping along the roots, and so upwards into the trunk; the attacked trees, however, are soon killed. But what causes the hollowing of our Ash, Willow, and Oak-trees? In a communication I made some time ago, I pointed out how the Oaks of Sherwood Forest were affected when they fell a prey to Polyporus sulphureus—by having the whole of the interior of the trunk destroyed. P. ulmarius does the same for the Elm; but what is the cause of the Willow losing its interior? This is a question well worth working out, for Willow wood has a distinct commercial value for certain purposes. The note on "A Mammoth Willow," on p. 215 of the *Gardeners' Chronicle*, April 8, 1899, shows how comparatively seldom these trees attain any size in a condition of commercial value. *C. B. P.*

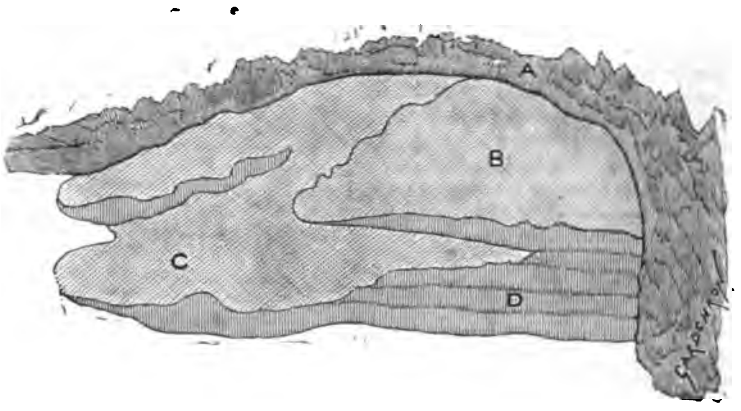

Fig. 143.—Polyporus ulmarius: parasitic on the elm.

A section showing the stratose tubes, from a semi-effused specimen growing on the upper side of a hollowed main root of an Elm, at Ashwicken Hall, King's Lynn, April 3, 1899.

A, Rotten wood; B, Last season's pileus included in this season's; C, Sporophore; D, Stratose tubes. *C. B. P. ad nat. del.*

Ditopella fusispora, *De Not*, an Alder-destroying Parasite.

During the past winter my attention has been directed from time to time to the Pyrenomycetes of the common Alder (Alnus glutinosa). In the month of February, some observations were made which may be of interest. February is the month *par excellence* in which to find the Sphæriaceæ in fruit, as the late Mr. Frederick Curry pointed out to me more than thirty years ago. By fruit, we then meant ascigerous fructification, and in those days our interest was with what the fungus was like, whereas, now it is more with what it does. No one dreamed at that time that Sphæria ditopa, Fr., as it was then called, was anything but a saprophyte which grew on dead Alder sticks, because they were dead. That the Pyrenomycetes are many of them true parasites seems somewhat difficult for us in this country to grasp, so essentially conservative are we in our intellectual proclivities, yet such is the case; although many of the Spheriæ are both saprophytic as well as parasitic in their mode of life.

The fungus in question (fig. 144), is found upon dead Alder twigs while they are still attached to the trees. The bark of the affected branches assumes a bright red-brown hue, which contrasts strikingly with the dark greenish hue of the bark of the living twigs. If an affected tree or bush be examined, it will be seen that while many of the red-brown shoots are dead quite down to their attachment to the trunk, yet there are very many in which the tips only have lost their vitality, as in the specimen sent (fig. 144, ^{1}). The line of demarcation between the dead and the living tissues is so abrupt, that it is evident the tree has made an effort to limit the inroad of the parasite, in much the same way as gangrene is limited in animal tissues. Another point is that the fungus is a wound-parasite, for the affected twigs all show an old injury of some sort. This may be a broken end where an animal has bitten a piece off, or partial break; a "green stick fracture" from somebody or something brushing roughly past, or where a minute lateral spray has been knocked off, or even a clean-cut end, the wound made by a pruning-knife or a hedge-trimmer's tool. On the dead portion of the twig one finds a number of black dots, the ostiola of the perithecia, which not only project just above the epidermis, but are the summits of distinct conical elevations, caused by the upheaval of the cuticular layer of the bark by the perithecia; these can be both seen and felt. If the outer layer of the bark be peeled off, the perithecia will be found to come off with it, and to adhere to its under-surface as little black dots (fig. 144, ^{2}).

Should the examination happen to be made where the fungus is in full vigour, the perithecia will be seen as plump, spherical, black bodies, like Mustard-seed, filled with whitest jelly (fig. 144, ^{3}). If the plant is past its best, or if the twig be thoroughly dry, then the perithecia will be collapsed, and instead of being spherical they will be concave or saucer-shape (fig. 144, ^{4}). Much, therefore, depends upon the time of the year the dissection is made. Dead twigs hang on Alder bushes all the year, and probably for more than the year, but the perfect fungus will only be encountered during the winter months, say, between December and March. Its mycelium would be present, no doubt, in an active, but by no means an easily recognisable condition until the perithecia are formed. The whitish jelly consists of a mass of asci and sporidia. The asci are about 100 m.k. long, and 15 wide (fig. 144, ^{6}). The sporidia (fig. 144, ^{5}) are numerous, 15—25 by 2—3 m.k. Dr. Rehm thinks there are 24 in each ascus, but they are very difficult to count, as they adhere to one another.

Ditopella fusispora is not the only pyrenomycete parasite upon Alder; for as long ago as 1888, Dr. E. Rostrup, in a paper entitled, "Under sægelser over Snyltesvampes Angreb paa Skovtrær," 1883—1888, p. 224, has shown that Cryptospora suffusa in its ascigerous condition, is parasitic in habit; while more recently V. Tubeuf in 1892, in a paper entitled, "Zwei Feinde der Alpenerle," shows that in the Alps, Alnus viridis is the host of Valsa oxystoma, Rehm, and that considerable injury is caused by it in the Tyrol. In the account of Tubeuf's work on this point, as given in the English translation of his *Diseases of Plants*, p. 226, a curious slip occurs, where it is said, "Most of the other species of Valsa cause only leaf-spot, or occur on dead leaves;" since Valsa is not a folicolous genus at all, but purely corticolous. *Charles B. Plowright, M.D., King's Lynn, Norfolk, April* 10, 1899.

FLOWER NOTES FROM EDGE HALL, MALPAS.

Never was a more complete transformation effected in a garden from a nearly flowerless condition at the end of May to a general gay display on the tenth of June. So long a series of cloudless suns is very rare here, and recalls to me the time a few years ago when an enthusiastic neighbour used to drive 3 miles at seven in the morning to catch my Cistus flowers at their best. All my gayest hardy plants are on borders and slopes facing the East, and the way to admire all flowers is with the sun at your back. But when the light has got round into the western half of the sky the effect is spoilt, for hardly any flowers can face a western sun in its full blaze without having a withered look. In short, as a general rule East is the best aspect and West the worst for hardy flowers, and early morning is the time to see them in summer.

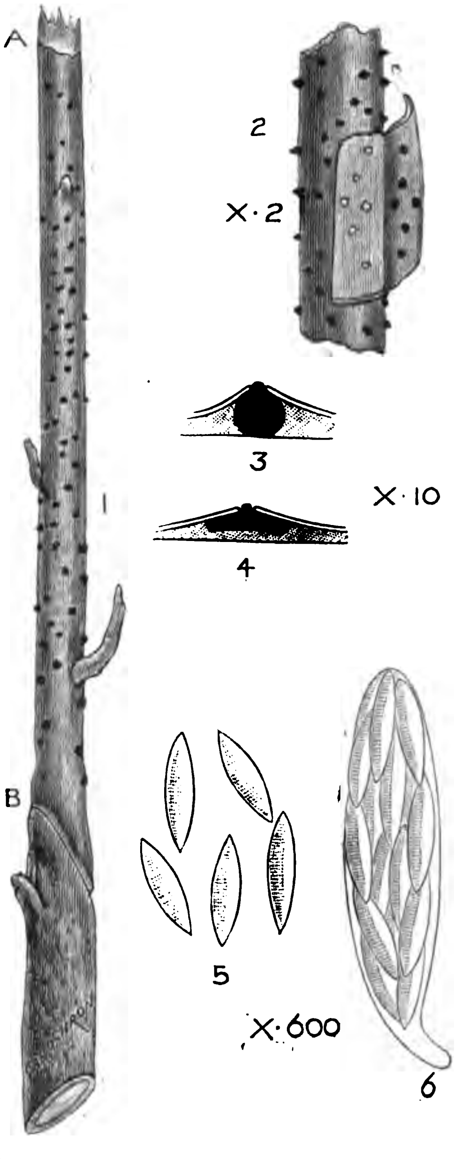

Fig. 144.—Ditopella fusispora: a parasite of the common alder, Alnus glutinosa.

1. A twig, the upper part of which has been killed by the parasite. The upper end (A) shows an old fracture, through which the parasite gained admission. Towards the lower end the line of demarkation between the dead and living tissues (B) is very distinct. The perithecia are scattered over the affected area (reduced half).
2. A portion enlarged 2 diameters. A piece of the epidermis has been lifted up and rolled back, showing six perithecia adherent to it; on the corresponding surface of the bark, depressions are visible into which the bases of the perithecia fitted. Scattered over the rest of the fragment, the prominent black ostioles of numerous other perithecia are to be seen.
3. A perithecium at maturity (×10).
4. A perithecium from which the sporidia have escaped, leaving it collapsed and empty. The same collapsed condition occurs from simple desiccation (×10).
5. Five sporidia (×600).
6. Ascus containing numerous sporidia (×600).

Charles B. Plowright, M.D., ad. nat. del.

Poppies and Irises seem never to find the sun too bright. The best perennial Poppy I have is Mr. Carrington Ley's hybrid of P. orientale; it will never be common, because few gardeners will take the trouble to nurse it up from small pieces, as it requires. But I have now several plants of it 4 feet across, with thirty or forty flowers open at a time, with the prospect of a second edition in autumn. The flowers support themselves on elegantly-curved stems, at different heights from the ground. A contrast to this is the upright and stiff-stalked P. bracteatum, 6 feet high, with huge deep blood-red flowers, which I raised from seed as a novelty in my garden at Eton fifty years ago, and have had the original plants, propagated by divisions, ever since, and still consider it by far the best of the polymorphous Oriental Poppies.

About Irises I cannot boast much. Last year the flag Irises, commonly called "German," were attacked in the leaves by a destructive mildew which seemed to descend from the top to the bases and rot the tuber. I dug up and burnt all the worst, following the usual advice of plant doctor, in such cases. Those which were spared are now flowering more profusely than I ever have seen them doing, and I look in vain for a trace of last year's mildew.

St. Bruno's Lily is a beautiful plant, which is worth improving by selection. The old type, dwarf and compact, has some tendency to hide the flowers amongst the foliage, whilst the form called in nurseries majus, or giganteum, flowers only on the part of the stalk above the leaves, and looks overgrown and top-heavy. But there is every intermediate, and they grow altogether, as I have seen them, in the same valley in the Pyrenees; and as they seed freely in gardens, selections may be made with foliage thin and flower-stalks plentiful. In parts of the garden where a wilderness is allowed to prevail, Thalictrum aquilegiæfolium and Asphodelus ramosus are now making a great show. An authority in art told me I ought to weed out the purple meadow Rues, growing only the white; but I own I like them mixed, as I have seen them by their native streams in the South of France. As for the Asphodel, the same friend was delighted to see it, as she only knew before the pretty name and the pretty fable of the Elysian meadows where it grows. It is true that a dense mass of these stout stalks, 6 feet high, might rather impede the free movement of mortals, but ghosts might float through them without inconvenience; but perhaps the Asphodel which Homer knew was quite different from what men now call by that name. Heuchera sanguinea suffered very much from the wet winter followed by hard frosts, and is only now recovering partially; but a hybrid of it with H. cylindrica, having flowers of a varied and lively pink, is much more hardy, and is now very full of flower. This is the best of several hybrids which H. sanguinea has produced in my garden, and ripens seed which grows into many fresh varieties of colour, from white to scarlet. Incarvillea Delavayi, a Chinese perennial, now getting into general cultivation, with pink flowers like those of a very large Mimulus, has done very well this year. It hardly looks as if it would rough it in an ordinary border; if it does, there will be no limit to its quantity, as it seeds abundantly, and is easily raised. For one or two winters it seemed as if it would not be hardy, but with a small pyramid of ashes over the crowns, and a well-drained position, more than a dozen plants in different parts of the garden seem all to have survived; and some have two or three stalks, each bearing two or three flowers. The orange-coloured variety of Meconopsis cambrica, which I brought some years ago from the Pyrenees, seems a more robust form with larger flowers than the yellow type; but it has not the bright orange to be found in Papaver nudicaule.

Speaking of orange-coloured flowers, why is Trollius "Orange Globe" so named? I bought it, expecting it to be orange-coloured, and when I sent a flower and a remonstrance to the nurseryman, he told me it was quite genuine and orange—but I call it yellow. I have for several years grown Trolliuses (hybrids, I believe, of T. asiaticus), and improved them by selection till I have a strain of the colour of Calendula officinalis. The so-called "Orange Globe" is a fine handsome flower, which I cannot beat for size, but is far from being of that colour.

I will mention only three alpines. Æthionema grandiflorum, some of the plants densely flowered, and 2 feet across, is the brightest ornament of my rockery, very vivid pink. My friend the lady artist, mentioned above, tells me I ought not to admire the colour, as it is "too pink;" but I do admire it—very much. Another alpine of which I am proud, which is also very bright pink, is Lychnis Lagascæ. For many years I could never keep it through winter; the tender perennial stalks were broken to pieces by snow and frost; but I now grow it in abundance on the perpendicular face of a brick wall, where it thrives wonderfully, some of the plants being several years old, and 9 inches or more across, and now quite full of flower.

Lastly, Oxalis enneaphylla, a very elegant and distinct Sorrel from the Falkland Islands, has now proved itself quite hardy through several winters. The climate of the Falkland Islands is much milder in winter than that of England, ice seldom being half-an-inch thick; but I have now several good plants from there which the storms of their native land seem to have prepared to resist greater cold than they have felt at their home. *C. Wolley Dod, Edge Hall, Malpas, June* 10.

PLANT NOTES.

IVY-LEAVED PELARGONIUM "MRS. HAWLEY."

THIS is a new variety raised by Mr. Hawley from Souvenir de Charles Turner, and is being distributed from the Royal Nursery, Slough. It was brought before the Floral Committee of the Royal Horticultural Society at the recent Temple Show, but not in good condition; and it was thought by some to be too much like the variety from which it originated as a seedling. In one of the Pelargonium-houses at Slough, there is, on a plant-stage, a large batch of each of the two varieties, placed there for the purposes of comparison. This comparison enables the points of difference to be noted. Free in blooming as the parent is, the child surpasses it; its wonderful floriferousness is one of its leading features; the flowers have more of crimson in them, and less of magenta than those of the parent; they are therefore rightly described as being darker, while the habit of growth is quite distinct. There are a large number of plants in 48-pots, and they serve as a suitable illustration of the marvels produced under good culture in a 48-sized pot. As a decorative ivy-leaved Pelargonium for decorative purposes, bearing double flowers, it is well worth cultivation. Of its entire distinctness I have not the slightest doubt, after an opportunity of seeing the two side by side. *R. D.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. YOUNG, Orchid Grower to Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen.

Cattleya Skinneri and C. S. alba.—Although most Cattleyas succeed when grown in baskets, these should not be used generally owing to the difficulty that arises when the plants need larger ones, it being necessary to place the old basket bodily into a new and larger one, to prevent irreparable damage to the roots. But for the species C. Skinneri, nothing serves the purpose so well as teakwood baskets, and providing the potting operation be performed in an efficient manner, a long period will elapse before a larger one is required. Plants whose growths are still within the confines of the basket need be re-surfaced only with new peat and fresh sphagnum-moss, first removing as much of the old material as may be done without injuring the roots. Other specimens may be carefully removed from the baskets they are now growing in to others of larger sizes. So dispose the rhizomes that the growing point will incline towards the centre of the basket. Use plenty of crocks, and, with the exception of those pieces placed at the bottom of the basket, the rest should be placed in as upright a position as possible. The plants will thrive best if suspended from the roof, or, failing this, they should be raised considerably above the stage, so that abundance of air may circulate around them.

C. Bowringiana and C. citrina.—C. Bowringiana is now making new growths, and great care is needed in watering the plant. The species requires a long, complete rest, and even now only sufficient water to prevent the bulbs shrivelling should be afforded. Place the plants in a light position in the Cattleya-house, and do not permit thrips to obtain a foothold. C. citrina having flowered, should be suspended in a light and airy position in a cool-house, and be afforded sufficient water as will prevent the newly-made pseudo-bulbs from shrivelling.

Trichopilias.—T. suavis, tortilis, crispa and marginata succeed best in baskets, which are suspended from the roof of the Cattleya-house, in a position where there is the greatest degree of shade, and excepting when the plants are rooting actively, a very moderate supply of water is needed. In most instances the plants have passed out of flower. Pick away some of the old potting material and resurface with good peat and fresh sphagnum moss, using the latter sparingly. Any specimens requiring new baskets, should be carefully removed by taking out the corner pins of the baskets, and afterwards the bars separately. Afford a good supply of drainage materials, and surface with fibrous peat and a few bits of sphagnum moss. T. coccinea, and T. (Helcia) sanguineolenta, require to be grown in pots, otherwise the above treatment will be suitable. T. fragrans, and the large-flowered form, nobilis, need a cooler temperature, and I generally place them with the Odontoglossum crispum, the treatment they require being similar. But when the bulbs have become matured, water will only be required at long intervals of time.

THE HARDY FRUIT GARDEN.

By C. HERRIN, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Sweet Cherries.—The fruits on the earliest Sweet Cherries on wall-trees are swelling rapidly and changing colour, and the trees should be covered with nets to safeguard the fruits, or the blackbirds, thrushes, and starlings will devour them as fast as they change colour. Bigarreau de Schreken, a good and free-cropping Cherry, is one of the earliest, and fruits of this variety are now nearly ready for consumption. In suspending nets from the top of a fruit-wall, a few forked sticks should be made use of for keeping it far enough away so as to prevent the birds reaching the fruits through the meshes; at the base it may be pegged out a yard or more away from the wall. The ends should be carefully secured to the wall. Should black-fly infest the shoots, the points of those not required to be laid in should be removed and burnt, while for those which must be retained a strong extract of Quassia should be prepared, and the points dipped in it, as syringing or wetting the fruits with this bitter insecticide is not permissible at this date. Trees of later varieties should be afforded water copiously at the root weekly, more especially if the weather be hot and dry, and the land of a light nature.

Currants and Gooseberries.—These fruits are making a good deal of growth, and the laterals may be stopped by pinching out the point of the shoot at the fourth or fifth leaf. Currants are often infested with fly on the points of the young growths, and the pinching destroys many of the aphides. The main shoots of young bushes, or those whose size it is wished to increase, should be allowed to extend without stopping the points. These may be dressed with Quassia, as recommended for Cherries. Where large ripe Gooseberries are required for the dessert, the more heavily-cropped bushes should be thinned of some of the unripe fruits whilst these are still small. If red-spider appears on the foliage, afford the bushes two or three drenchings with the garden-engine on successive evenings, making use of a weak solution of Gishurst Compound-soap and water, or strong soap-suds made with soft-soap; and a few days afterwards apply clear water to clean the bushes of all traces of soap.

Caterpillars of the Gooseberry Saw-fly.—If the attack of these troublesome creatures is not a severe one, hand-picking or shaking the bushes after spreading a sheet beneath the bush will suffice to clear them. The poisonous Hellebore-powder, commonly recommended for this kind of insect destruction, should only be used when other means have failed.

THE KITCHEN GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet.

Potatos.—The plots of late Potatos should now be moulded up, first hoeing between the rows, and pulling up any large weeds. Should the soil have become hard, let it be dug with a fork carefully between the rows, after which the earthing-up may be done. Field-potatos should be scuffled with a horse implement to destroy weeds, choosing dry weather to do the work; and when the tops are high enough, lose no time in earthing them up with a moulding-plough, otherwise a good deal of damage may be done to the tops and tubers.

Cardoons.—Although this vegetable is not generally cultivated, it makes a nice addition to the list of culinary vegetables. The plants, if the seeds were sown at the proper time, should now be in a fit state for planting out in the trenches, prepared as for Celery, excepting that they may be a trifle wider and deeper. The plants may be set out at 18 inches apart. The plants having been raised in pots, should be turned out with care, and when the planting is finished, the whole should have a good application of water which has been warmed by exposure to the sun.

Peas.—Should the weather remain dry, afford water freely to the soil on both sides of the rows, using alternately with clean water some kind of liquid-manure, mulching the entire space between the rows, or only for a foot or so alongside the rows, with half-decayed manure. If water be plentiful, Peas should be afforded an occasional syringing. The rows of late Peas, before being earthed up, should be weeded or hoed, then afforded water on both sides, and soon afterwards the soil should be drawn up to the plants and sticks put to them. In dry weather mildew and thrips have to be guarded against, for they check the plants and cause them to pod too early, which makes it difficult to keep up a regular supply for table. In order to avoid this, afford water abundantly at the roots, alternated with manure-water. Copious syringings will help greatly to keep the plants free from thrips. The last sowing may consist of tall Marrowfat early varieties, sowing the seed in well-moistened trenches. This sowing will afford pods in October, provided they are not cut off or greatly checked by frosts. The drills or trenches for this sowing may be made a little deeper than usual.

Miscellaneous.—Make sowings at short intervals of time of Lettuce, Carrots, Radishes of the breakfast and Turnip-rooted varieties; of Spinach, Turnips, and Mustard-and-Cress.

THE FLOWER GARDEN.

By A. CHAPMAN, Gardener to Captain HOLFORD, Westonbirt, Tetbury, Gloucester.

Subtropicals.—The various species and varieties of the so-called subtropical plants impart an ornamental appearance to the flower garden and the dressed grounds surrounding a mansion if the sites of the beds are such as befit the plants, and the plants do not seem incongruous; and they are as admissible in a geometrical parterre as in the irregular flower garden, and in proximity to beds of herbaceous perennials as to those filled with the usual summer bedding plants, if only the position is appropriate. The aspect selected for them should be one with sufficient light to prevent the plants becoming drawn, at the same time affords shelter from the prevailing strong winds which would spoil their appearance. In preparing the beds, let good drainage be secured, and soil not less than 18 inches deep, consisting of rich loam two-thirds, and rough leaf-mould one-third. The surface of the bed should be so shaped that the centre rises gradually from the sides, and thus allows the plants to be seen to better advantage than in the case of a flat bed. Wigandias, large-leaved Solanums, Acacias lophantha, Ricinus, Abutilons, Funkias, Rhus. Cannas, Aralias, Melianthus major, variegated Maize, which last-named, if it be grown in pots, and these plunged in the soil, will keep its variegation perfectly; and Acer Negundo foliis variegata, grown in the same way, contrasts well with the darker foliage of the other plants. All subtropical plants should be thoroughly hardened-off before being planted out, and they require liberal feeding, and plenty of water when growing, especially those possessing large leaves, which, in a certain degree, prevent the rain from reaching the roots of the plants.

Begonias.—The fibrous and tuberous-rooted Begonias may now be safely bedded-out. These plants are easy of cultivation, providing their needs are well considered at the first, that is, the beds should be exposed to direct sunlight, be well drained, and consist of a moderately retentive soil. Should the staple be of a hungry nature, it is well to add leaf-mould, charred soil, and hot-bed manure, putting one wheel-barrow load of the latter per square yard of the soil, well mixing the whole with the staple, and after levelling and shaping the beds, make the whole moderately firm by trampling. If a bed consists of Begonias alone, the distance at which the plants will be set will depend on their size. If they are plants of this year, 9 inches will be sufficient; but two-year-old plants will require from 12 to 15 inches. The crown of a tuber should not be buried deeper than from 2 to 3 inches, and the soil must be pressed firmly round the ball of earth and roots. Having planted a bed, afford water liberally, and afterwards let the surface of the bed be kept somewhat loose with the Dutch-hoe. A slight sprinkling overhead with a fine-rose watering-pot after a hot, dry day refreshes the plants. When in full growth, Begonias may be afforded water rather freely. Where special colours in masses are required, seedlings are not to be relied upon, and the plants employed must be selected as regards habit, height, and character and colour of the blooms, but as a rule habit and shape and size of flower in improved strains go together. In beds of mixed colours one cannot go wrong in selecting the dwarfer seedlings, and these if they have been raised early in the year will now be showing the colour of their flowers. Effective beds are formed by planting the Begonias further apart than is stated, and planting a groundwork of Sedum acre and S. glaucum, and Saxifragra hypnoides, or they may themselves be used as a groundwork to taller plants with variegated foliage, the colours blending or forming an agreeable whole.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Codiæums and Dracænas.—The present is a very suitable time for the propagation of these plants in quantity for decorative purposes during the winter. Plants which have become too tall may be headed down, and the young part of the tops inserted in small pots, and these plunged in the propagating-frame. The stock of Dracænas may be further increased, if necessary, by cutting the stems of the plants from which the tops have been taken into pieces about 2 inches in length, and inserting these thickly in pans filled with sandy soil, taking care that they are not placed upside down, and keeping the tops of the cuttings level with the soil. When they have produced a shoot and made a sufficient number of roots, the cuttings should be potted into small pots, and subsequently into others of a larger size, and grown on until the plants form good tops. The propagation of Dracænas may also be effected by means of the fleshy rhizomes, commonly called "toes," which are frequently found near the base of the roots of old plants. These may be cut off and inserted singly in small pots, and treated similarly to the stem-cuttings. A position near the glass in a light house, with a stove temperature and an abundance of atmospheric moisture during the growing season, are essential to the production of highly-coloured Codiæums and Dracænas.

Miscellaneous.—The points may be pinched out of the shoots of Allamandas which are growing freely after being cut back; doing this increases the number of flower-shoots. Hardy and half-hardy annuals which are being grown in frames for conservatory decoration may, after being hardened by increased ventilation, be stood in the open air. Remove the flowers and flower-stems from zonal Pelargoniums which are being grown for autumn and winter flowering, and pinch the shoots occasionally, in order to produce bushiness. Show Pelargoniums should be stood in a sunny position out-of-doors after flowering, to ripen the growth and rest the plants. Afford only occasionally water during dry weather, and in rainy weather lay the plants on their sides.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

The Latest Vinery.—The Grapes will now be ready for thinning, and where Lady Downes, Alnwick Seedling, or Gros Colman comprise the sorts grown, very careful thinning will be needed. For late-keeping Grapes a much freer hand is desirable; crowded bunches are always bad keepers. The berries of Lady Downes and of Gros Colman are borne on short, stiff stalks, and they consequently need to be thinned severely, irrespective of late keeping, than such long-stalked berries as Black Hamburg. Alnwick Seedling is a fine mid-winter Grape, but the blooms do not always set regularly, and the final thinning of berries and of bunches of this variety may be deferred a short time. The work of tying down the laterals should precede the thinning, and no crowding of these must be allowed. Encourage rapid growth by closing the house early in the afternoon, and maintain a fair amount of warmth in the hot water-pipes at night. Remove all useless lateral growths once each week, pinching them back to within one joint whence they issue after the first stopping. If any of the old canes have grown unsightly, encourage a young rod from the base of the existing ones, allowing this to extend to about 8 or 9 feet before it is finally stopped. Vigorous Vines will furnish the roof with a new rod in two or three years. An unsatisfactory Vine can often be replaced by extending an adjoining one, and this is more satisfactory than planting a young Vine in an old border. In bad cases it may be advantageous to cut an old rod back to the height of the front trellis, in order to induce a satisfactory break. In this there is the sacrifice of a year's crop, but the practice often produces such an improvement that the loss is well repaid.

The Early Peach-house.—Fruits of the earliest Peaches and Nectarines having been gathered from the trees, let all the shoots which have borne fruits be removed so far as they can be spared, and tie-in those of the current season's growth, in order to cover the trellises without in the least crowding the new wood. Admit air abundantly by night and day, so as to keep the temperature low. Houses that are lightly built are better for being slightly shaded, either by syringing the glass with prepared summer-shading or whiting mixed thinly with milk. A double thickness of fish-netting drawn over the roof would serve the purpose as well, if not better; but anything affording much shade must be avoided. A slight amount of shade not only prevents a high temperature, but checks premature ripening of the wood, buds, and foliage, to which may be attributed much of the trouble caused in the winter by bud-dropping. Red-spider is much in evidence this summer, encouraged, no doubt, by the sudden access of temperature, and the daily syringing of the trees should not be relaxed, but rather more vigorously applied where spider is present, or irremedial damage will be done. The borders should have copious applications of water, especially such of them as are filled with young roots. A mulch to such borders is a great value in conserving the moisture in the soil and keeping it cool. Pot-trees having been cleared of their fruits may be plunged in the soil outdoors, in a partially shaded position at the first, as too much sunshine may cause them to drop their leaves early. Afford the soil in the pots a thick mulch of strawy litter, and water whenever the soil is found to be getting dry. A daily syringing morning and evening will keep these trees healthy and free from insects.

The Second Early Peach-house.—The fruits of Peaches Dr. Hogg, Bellegarde, Stirling Castle, Dymond, Royal George, A'Bec, and Hale's Early, now ripening generally, will, with careful ventilating and shading, be made to prolong the season of forced Peaches for some time longer. Let all fruits that are fit for table be plucked every morning, and do not neglect the daily syringing of the trees in sunny weather. It is advisable in syringing trees having ripening fruits upon them to do this early in the afternoon, so that the foliage and fruits may become dry before nightfall. The fruit of the Nectarine is more liable than that of the Peach to split if much wetted when ripening. The water used at this stage should be quite clear, as dirt cannot be removed from the skin of ripe fruits. Let the fruits be as much exposed to the sun as possible during the final swelling, or the colour will be poor, and flavour not of the best. The second early house is the better for having constant ventilation after this date. Suppress all superflnous laterals, and tie-in the shoots neatly as occasion may require; pinching back secondary growths to one leaf. Bare spaces in established trees can be furnished another season by inserting wood-buds in the branches at the present time, taking them from strong shoots on healthy trees. The methods adopted with Roses is suited to the budding of the Peach or Nectarine. It is only from the early-started trees in forcing-houses that such buds can now be obtained, and these buds should be inserted near the base of the most convenient branches, and always on the upper side of them. It is always well to put a label bearing the name of the variety on the budded branch. Seedling trees, if strong enough, may be budded, but not placing more than one variety on one tree.

THE APIARY.

By Expert.

Returning swarms.—When swarms are not desired, all queen cells should be removed immediately after the swarm has issued, and in the evening the bees may be returned in the usual way. Examine and make sure that all queens of this year are laying, if they are, encourage them to breed as many young bees as possible before ovipositing ceases for the season. Such will make the very best stocks for future work.

Ventilation.—If bees exhibit signs of distress by hanging out in very hot weather, give ventilation at the bottom of the hive by raising it up a little from the floor-board, lowering it again at night. Hives with sliding floors may have them withdrawn a little, or lowered at the front, during the hottest part of the day; entrances also should be enlarged as much as possible, and shaded if it can be conveniently done. Sometimes it becomes necessary to remove the wrappings of surplus boxes, and to slightly raise the roofs which cover them, in order to allow a current of air to play about the supers. It is, however, not often needful to take all these precautions, unless in exceptionally hot summers, when more care than usual is required, but a little extra attention at such times is well repaid.

GRAPES IN SURREY.—The *Surrey Magazine* for May, mentions that:—"Mr. Bennett, of Cobham, among other Surrey growers, produces Grapes of the first quality by scores of tons in a crystal-covered field, and worthy of special mention is the most remarkable Vine in Britain, as raised and grown by Mr. M. Davis, at Roehampton. Its seven main stems extend in the aggregate more than a quarter of a mile, and the Vine dwarfs beyond all comparison the famous old monarch at Hampton Court. It produced fruit for the royal table on the occasion of the Diamond Jubilee, and when the Vine was inspected by Paderewski, the great master was so charmed that he charmed the family of his guide in return by filling the gardener's cottage with melody on Miss Davis's piano—a performance of its kind that may be regarded as unique!"

WEDDING OF A WELL-KNOWN GARDENER.—On Wednesday, 14th inst., at St. George's, Hanover Square, the marriage took place of Mr. E. T. Gilman, for many years head gardener to the Earl of Shrewsbury and Talbot at Ingestre Hall, Staffordshire, and of late years in charge of the gardens at Alton Towers, Cheadle, and Miss E. Butters. The ceremony was largely attended by the friends of both parties, and the reception was held after the wedding by the kindness of Mrs. Alfred Morrison, at 26, Bruton Street. The happy pair received a large number of presents from their mutual friends, and they left for Brighton in the afternoon for the honeymoon.

EDITORIAL NOTICES.

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	June 19	Royal Agricultural Society's Show at Maidstone (5 days).
TUESDAY,	June 20	Royal Oxfordshire Horticultural Society's Show.
WEDNESDAY,	June 21	Rose Show at Shanklin, Isle of Wight.
FRIDAY,	June 23	—Royal Botanic Society, Lecture.
SATURDAY,	June 24	Windsor Rose and Horticultural Show. Royal Botanic Society, Meeting.

SALES.

WEDNESDAY,	June 21	Begonias, Palms, Greenhouse Plants, Japanese Lilies, &c., at Protheroe & Morris' Rooms.
FRIDAY,	June 23	Imported and Established Orchids at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period June 4 to June 10, 1899. Height above sea-level 24 feet.

1899. June 4 to June 10.	Direction of Wind.	Temperature of the Air. At 9 A.M. Dry Bulb.	Temperature of the Air. At 9 A.M. Wet Bulb.	Temperature of the Air. Day. Highest.	Temperature of the Air. Night. Lowest.	Rainfall.	Temperature of the Soil at 9 A.M. At 1-foot deep.	Temperature of the Soil at 9 A.M. At 2-feet deep.	Temperature of the Soil at 9 A.M. At 4-feet deep.	Lowest Temperature on Grass.

Remarks.—The weather during the week has been remarkable for cold, drying winds, mostly from the east. No rain has fallen since May 24.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—61·6°.

Actual Temperatures:—

London.—*June* 14 (12 p.m.): Max. 60°; Min. 45°.

Provinces.—*June* 14 (6 p.m.): Max. 62°, W. Ireland; Min. 52°, N.E England.

Fine; no rain.

Botanical Nomenclature.

The intricacies of botanical nomenclature are perplexing enough to experts, and in spite of conferences and congresses there are still many who prefer self-made law to any other. The attempt to secure uniformity of practice seems doomed to be futile; it is, therefore, not surprising that gardeners should feel that they too have a right to make use of terms in their own sense without regard to the authority of others. In most cases, as in certain more serious matters with which the public mind is concerned just now, the matters in contention are essentially trivial and relatively unimportant.

It is convenience rather than principle that is at stake in most of these questions of nomenclature. Provided that the meaning in which a particular term is used is clear alike to him who uses it, and to him to whom it is addressed, the actual term made use of is relatively unimportant, unless for historical purposes. Nevertheless, much confusion will be avoided if some sort of agreement can be come to, and hence, while we object to certain details, we welcome the efforts made by the Royal Horticultural Society (the second edition of whose *Rules for Judging* has just been published) and other bodies to give precision to certain terms for the guidance of judges and others.

Some schedule makers and many gardeners are great offenders in the way of nomenclature; and some judges, from whom we look for accuracy, are no better. In the *Rules for Judging*, even, we find such expressions as the "Brassica tribe," and that "all natural genera are kinds, and all variations within a genus are varieties. Peaches and Nectarines, and the Cabbage tribe are notable exceptions to this; black and white Grapes are also for exhibition allowed as distinct kinds." We are expressly told that these pronouncements are arbitrary, and devised for exhibition purposes, else we might have protested against a method of grouping which excludes *species* altogether, and is in itself very confusing to those who are accustomed to the ordinary rules of botanical classification. What must it be to those untrained in the work of defining and marshalling groups of facts and phenomena? Orders, families, genera, species, sections, tribes, varieties, kinds, sorts, and so forth, are treated in ordinary language, as if they were of equal value and legitimately interchangeable—we have daily experience of this. It is as if we confused continents, islands, archipelagos, countries, provinces, peninsulas, counties, and parishes, and took one for the other indiscriminately; or, as if we attached the same meaning to army-corps, brigades, regiments, squadrons, companies, and so forth.

It is curious that whilst the absurdity in these cases is apparent to everyone, in the divisions of the animal and vegetable kingdoms it is otherwise. This may, perhaps, arise from the difficulty or impossibility of framing a precise definition of the word "species." Could we have a fixed unit as a starting point, its divisions and multiples could be made definite also. But in natural productions there is no fixity, but only a relative degree of constancy. A "species" we may take to include all those individual plants which had a common origin from the same original parents. But who is to prove that this was the case? Who can be infallible in such a matter? Not even the youngest of us! As Asa Gray said, species are "judgments." The wider and deeper the knowledge of the judge, the more deference we pay to his judgment.

Illustrations, in this case, are better than definitions. Here, then, is one: the Grape-vine, which botanists know as Vitis vinifera, is a species; it is the species "vinifera" of the genus Vitis. It happens to be the only European species, and therefore confusion is not likely to occur. But there are numerous American species such as Vitis Labrusca, &c., very much like, but amply differing from the European species; consequently the American Vines and the European Vines are placed in one genus called Vitis. In like manner there are other genera nearly allied to Vitis, but differing from it, such are Cissus, Ampelopsis, Leea, &c. These genera in their turn are combined into one natural order, the Vitaceæ, all the members of which are allied one to the other by ties of blood-relationship, so that, starting with species, we have progressively higher and more comprehensive groups of genera, orders, sub-classes, classes, and so on.

It is, however, with the lower groups, the sub-divisions of a species, that gardeners are most concerned, and here it is that the trouble with such vaguely-defined words as "kinds," "sorts," and "varieties" comes in.

A species consists of an infinite number of individual plants, which all had, or, from their great resemblance and the circumstance that their characteristics are generally, but not invariably, reproduced in their offspring, are assumed to have had, a common origin. But when we come to scan the individuals comprising the species, we find considerable variation among them, just as there is in a family of human beings, the offspring of the same parents. And thus we get various degrees or grades of variation, which botanists note as sub-species, varieties, variations, forms, and so on in descending order, each group less comprehensive than its predecessor.

Take the case of the Grape-vine again: Vitis vinifera varies greatly, but we do not think that the variation is sufficiently important to justify the formation of a sub-species, but that is a matter of opinion. Of varieties there are two principal ones, those with black and those with white berries respectively, and of each of these there are innumerable minor variations — Black Hamburghs, Alicantes, Gros Colman, Muscat, and so forth. This subdivision is intelligible to any botanist, and is in conformity with the rules accepted by the Paris Botanical Congress, presided over by the late Alphonse de Candolle.

Now, what place shall we give to the word "kind?" Where does it come in, in the above grouping? We have certain rules for judging before us, and we find, as usual, considerable variation even in this matter. The significance attached to the same word by the late Mr. M. Dunn in the last communication he ever wrote to us only a day or two before his death (see *Gardeners' Chronicle*, May 20, 1899, p. 320), is at variance with that adopted by the Royal Horticultural Society. For our own parts we should, for garden purposes, affix the word "kind" or "sort" to any group below specific rank, which is nevertheless sufficiently distinct to enable us to apply a name to it; thus, we should call Black Hamburgh a kind, Alicante another kind of Grape, and so on; just as in the case of Roses, we should esteem General Jacqueminot to be a kind, and Souvenir de la Malmaison to be another kind; or, in the case of dogs, retrievers, pugs, terriers, collies, bull-dogs, would all be "kinds" of dogs. If this be admitted, the word "kind" would be the equivalent in the hierarchy of botanical rank with "variation." The grading would thus be:—

Species.
  Sub-species (= race, strain).
    Varieties.
      Variations (kinds, or sorts).
        Forms.

The term "form" applying to transitory variations of minimum degree. Other people would prefer to consider "kind" as the equivalent of species, and the Royal Horticultural Society rules make it the equivalent of a "natural genus."

That this, or any other arrangement, will satisfy all people is more than can be expected: but if flower-show societies put forth their own definitions and interpretations, the least that exhibitors and judges can do is to conform to them loyally at the time, and to endeavour, if necessary, to amend them on another occasion.

Pyrus coronaria, *fl.-pl.* (fig. 145). — The type species with large, delicate, rose-coloured flowers, is one of the latest of the ornamental Pears to produce its flowers. The flowers and the long-keeping fruits, of the size of a Greengage Plum, emit a delicious odour of violets, which can be detected at a considerable distance. Bechtel's variety, P. coronaria, flore-pleno, flowers, as does the type, whilst completely clothed with leaves, and possesses large, double rose-like, fragrant blossoms, which render it one of the most beautiful spring flowering trees known to us. We are indebted to the kindness of Mr. Gumbleton, Belgrove, Queenstown, for the material from which our artist prepared the woodcut.

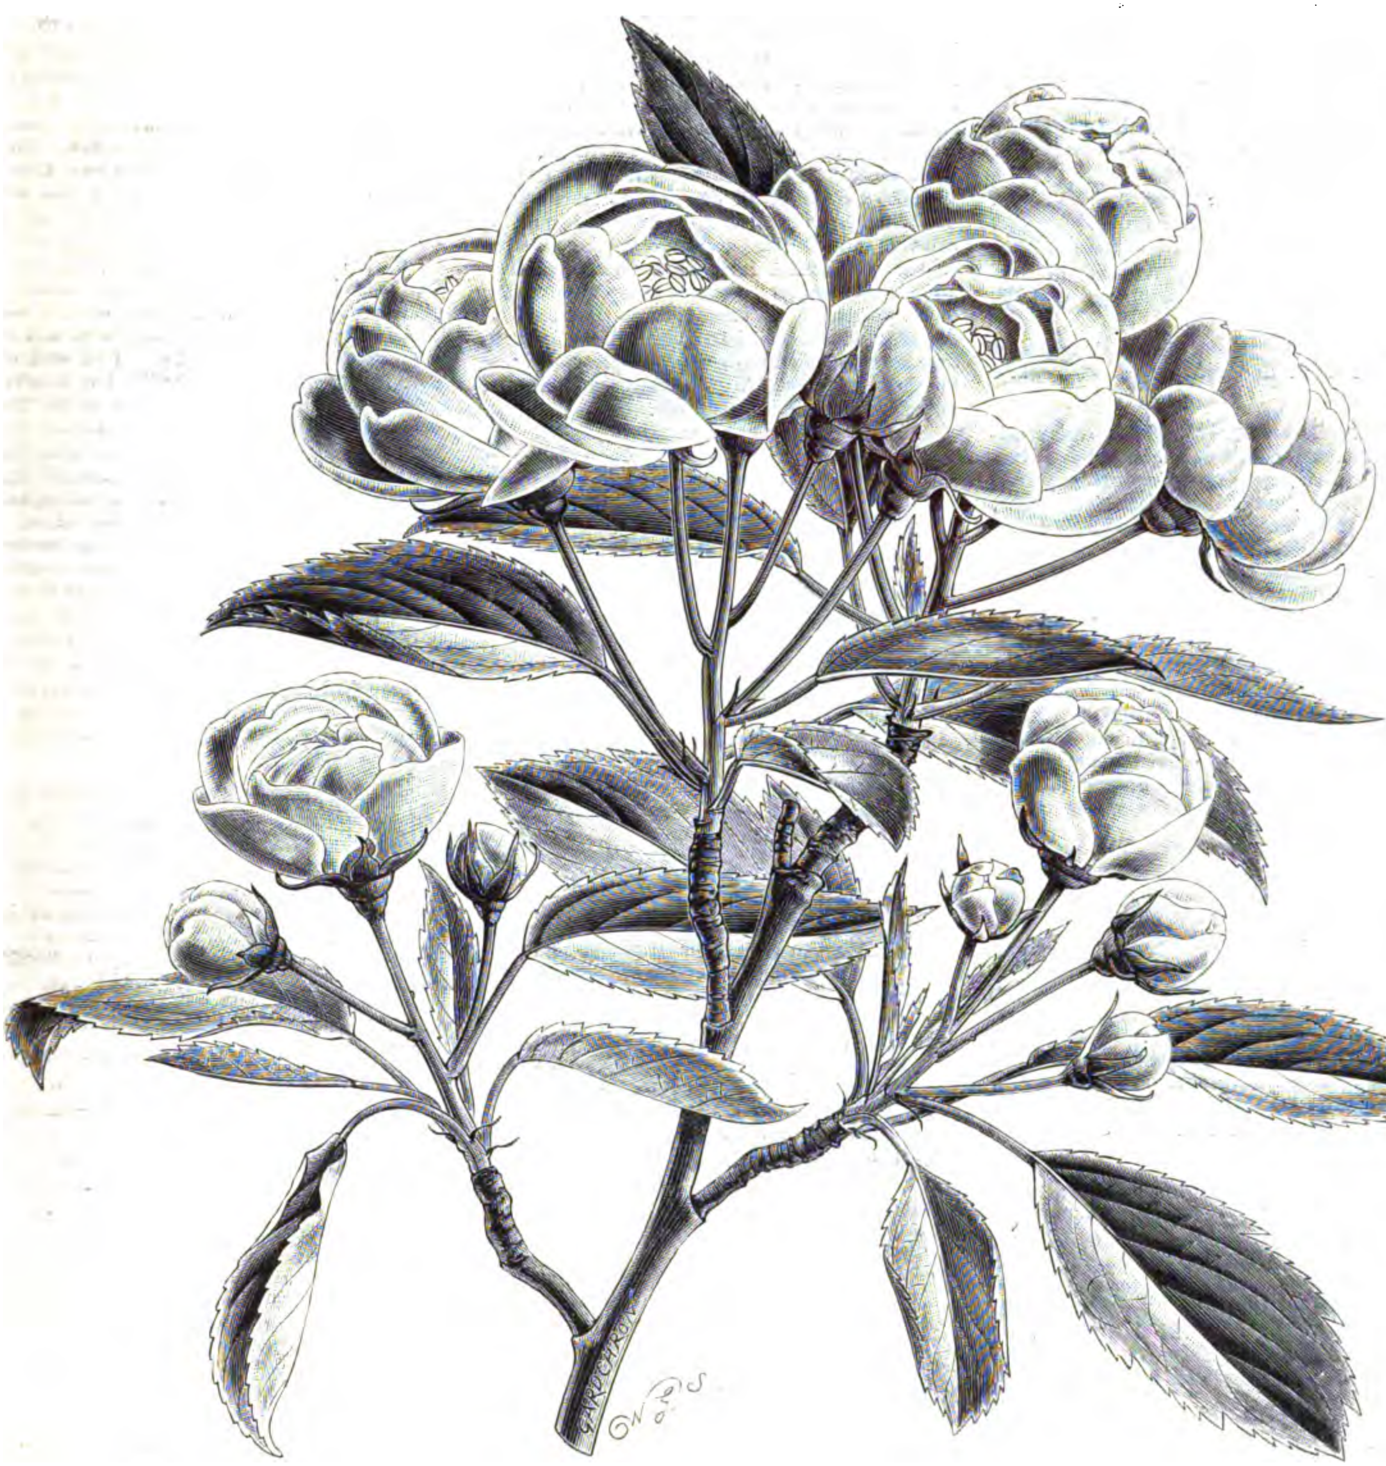

Fig. 145.—Pyrus coronaria, flore-pleno (Bechtel): colour of the flowers delicate rose.

Linnean Society.—June 1, 1899. Dr. A. Günther, F.R.S., President, in the Chair. Mr. W. B. Hemsley, F.R.S., F.L.S., exhibited a selection of High-level Plants from the collections formerly made by Sir Joseph Hooker, Dr. Thomson, General Sir R. Strachey, and more recently by Capt. Welby, Mr. and Mrs. Littledale, and Mr. Arnold Pike in Northern India, Thibet, and Mongolia, many of them from altitudes of 18,000 to 19,200 feet. A selection was also shown from the collections made in the Andes by Sir Martin Conway, Mr. Fitzgerald, Mr. Gosse, and Mr. Whymper, at various altitudes up to 18,500 feet. The principal points referred to were the small size of many of the plants, the protective woolly covering of others, and the general preponderance of the natural order Compositæ. On behalf of Mr. F. N. Williams, F.S.L., the Secretary read a paper on some Caryophyllaceæ from Sze-chuen, with a note on the recent Botanical exploration of that province.

The Dinner of the Royal Horticultural Society.—A large number of distinguished foreigners will be present at the Hybridisation Conference, and it is hoped that a large body of the Fellows will assemble to do them honour at the meetings and at the dinner on July 12, at the Hôtel Métropole. The hospitality shown to our countrymen abroad is a powerful inducement to us to do what we can on this occasion to reciprocate the kindness. Intending diners should communicate at once with the Secretary, Royal Horticultural Society, 117, Victoria Street, Westminster.

"BOTANICAL MAGAZINE."—The plates in the June number are devoted to the illustration of the following plants :—

Begonia venosa, Skan; t. 7657. This is the species introduced by Mr. Christy, and exhibited by him at one of the exhibitions of the Royal Horticultural Society. It is remarkable for its leaves covered with silvery hairs, and for its large stipules, with marked reticulate venation.

Moræa sulphurea, Baker. A small species with linear leaves, and small terminal yellow flowers. It is a native of the Cape; t. 7658.

Kleinia pendula, D.C.; t. 7659. A species with tortuous fleshy stems, minute leaves, and terminal heads of crimson flowers. Native of Somaliland.

Chrysanthemum nipponicum, Watson, in *Gardeners' Chronicle*, 1897, vol. i., p. 46, and in 1898, vol. ii., p. 348, f. 104; t. 7660.

Iris Delavayi, Micheli; t. 7661. A native of Yunnan. The "falls" are purple, with white blotches.

KENFIELD, CANTERBURY.—The extensive collection of Conifers which was formed by the late Mr. R. E. THOMSON, and plantod some fifty years ago under the direction of the late Alderman MASTERS, of Canterbury, is probably the best and most varied in the county of Kent. Fine examples of Sequoia (Wellingtonia), Abies Mertensiana, A. firma, A. Alcockiana, the rare Piceas bracteata, amabilis, nobilis, concolor, &c., being represented by large specimens. Up to the time of Mr. THOMSON'S death, novelties were constantly being added to the collection. The earlier introductions of Japan Maples were very conspicuous. During the absence of the present owner in India, the pinetum became much overgrown, and the werk of opening out the best and rarest trees has been entrusted to Mr. GEORGE BUNYARD, of the Nurseries, Maidstone.

NATIONAL DAHLIA SOCIETY.—The committee of the above Society have made arrangements to hold a meeting at the Royal Aquarium, Westminster, on Tuesday, September 19, for the purpose of affording an additional opportunity for the exhibition of seedling Dahlias, and for the awarding of the Society's First-class Certificate to such of the new varieties exhibited as the committee may consider worthy. In order to give additional interest to this meeting, it is thought desirable to offer prizes in a few competitive classes, and contributions for this purpose are solicited. The Hon. Secretary is Mr. J. F. HUDSON, Gunnersbury House, Acton.

THE HORTICULTURAL COLLEGE, SWANLEY.—The Governing Body have pleasure in announcing that the Rose garden, which has been laid out under the superintendence of the Very Rev. The Dean of Rochester, who has promised to be present, will be opened by the Viscountess FALMOUTH, on Thursday, June 29, at 3 P.M., when the college, grounds, and house of residence for women students will be open for inspection.

FLOWERS IN SEASON.—Among some of the showiest, as a filling for flower-glasses, &c., are the flowers of the hardy Chrysanthemum maximum. The flowers are very large, and they are terminal on long stalks, and have pure white rays and a yellow disk; and the plant growing in gardens to a height of 6 feet, it forms an admirable back-row plant in a border of herbaceous perennials, or for dotting in the shrubbery. Mr. JOHN DAVIS, of Hoylake, Cheshire, who sends the blooms, informs us that the plant has been in flower since May 22, although generally the season in that part of the country is three weeks later than the average.

DR. GÜNTHER RITTER BECK VON MANNAGETTA has been appointed Professor of Botany in the German University of Prague.

STOCK-TAKING: MAY.—The delay experienced in the issue of the Trade and Navigation Returns for the month of May is amply condoned by the work recorded—by the increase of imports from all parts of the world, and the enhanced value of the exports thereto. The value of the May imports was £40,876,828, against £37,706,378 for May, 1898, a gain of £3,170,450. This gain extends over nearly all sections of the returns. In the food imports we find Wheat increased by 436,850 cwt., but the value decreased by £1,033,706. It may appear strange to "the foreigner," but the value of the 4-lb. loaf does not show a very downward tendency. Barley has given way, but Oats increased in quantity by 443,470 cwt., and £104,737; eggs went up by £69,071; butter, £194,596; rice rose £280,085; sugar of all descriptions increased by £152,530; hams and bacon fell off both in quantity and value; whilst cheese showed an increase represented by £78,245. In dutiable articles tea shows an enhanced import, the value rising by £109,021; coffee decreased in value; cocoa increased by £52,435; wine dropped £68,694. With the exception of rum, all spirits show an enhanced value. But here we may fitly give our usual condensed summary of imports, as follows :—

IMPORTS.	1898.	1899.	Difference.
	£	£	£
Total value ...	37,706,378	40,876,828	+3,170,450
(A.) Articles of food and drink—duty free	14,420,133	14,395,844	—24,290
(B.) Articles of food & drink—dutiable	1,987,342	2,078,099	+90,757
Raw materials for textile manufactures	5,406,415	5,537,567	+131,152
Raw materials for sundry industries and manufactures	3,609,859	4,435,092	+825,233
(A.) Miscellaneous articles	1,008,643	1,186,984	+178,341
(B.) Parcel Post ...	110,127	87,187	—22,940

We should note that metals show an increase of £822,716; of this copper stands for £259,684, the quantity-column shows but little increase; the American ring is responsible for the rest. Of course, tin shows an increased value—£160,729; nil represents alteration in quantity as compared with May, 1898. Oils have gone up £204,054, the figures for petroleum showing an increase of £116,773—representing 7,053,786 gallons. In raw materials for textiles, cotton, Flax, silk, all show a reduction; whilst Hemp, Jute, wool show a rise. In other raw materials, a rise of £825,233 is shown; caoutchouc went up £185,124; gums, £32,797; wood and timber show a rise of £178,087; Clover and Grass-seeds have gone back, Flax or Linseed and Rape went up. The section relating to fruits, roots, and vegetables is, as usual, very interesting; our extracts are as under :—

IMPORTS.		1898.	1899.	Difference.
Fruits, raw :—				
Apples	bush.	97,400	127,422	+30,022
Cherries... ...	,,	10,385	33,751	+23,366

Vegetables, raw, unenumerated	value	£130,513	£136,600	+£6,087

Oranges seemed to "run over" from the vicinity of the Monument into every court and alley in the metropolis, "specks" being plentiful enough to sell at six for 1*d.*, and in proportion increased the danger to life and limb in the public streets. To close with the imports, it is satisfactory to record an increase on the five months amounting to £1,416,346; the figures for the past month being £198,403,349, as against £196,987,003 in May of last year. We pass now to a brief note on the

EXPORTS.

The increase here is £5,138,886, thus gained: the total for the month is £23,030,240; for May, 1898, £17,891,354, something like a rise. This is obtained, in part, as follows: new ships, not registered as British, foot up at £1,974,982; coal, coke, and fuel, £689,544; metals and articles manufactured therefrom, except machinery and ships, £844,810; machinery and mill-work, £218,617; raw materials, £724,342; yarn and textile fabrics advanced by £629,269. Here we may note that cotton piece goods rose £384,015; America taking largely, as also in the case of linens, which record again £56,933; all other articles, either manufactured or partly manufactured, have increased some £353,082, and here are included railway rolling stock, india-rubber goods, products of coal, £22,650; wool, in various conditions, £64,779; live animals were sent out to the value of £7,476; articles of food and drink, £34,979. But enough of the tale has been told to account for the increased activity in the British workshop and factory. The increase on the five months is placed at £11,447,244, the value for the five months just ended being £104,541,727, against £93,094,483 set against the corresponding term in 1898. To illustrate the thoroughness of our trade in the East, we make a note respecting the Chinese imports and exports. These are valued at 370,655,538 taels, to which the British dominions contribute 233,960,730 taels—over 60 per cent. As to the carrying trade of the Chinese Empire under foreign flags, Great Britain furnishes 80·74 per cent.; Germany, 7·28 per cent.; Russia, 0·81 per cent. These facts are worth remembering when discussion turns upon our position in that part of the globe.

"HARDY FRUITS FOR THE MIDLAND COUNTIES."—We have received a copy of Mr. A. H. PEARSON'S excellent paper on *Hardy Fruits for the Midland Counties*, which is now in its third edition. The information given was first published by the Nottinghamshire Horticultural Society in 1884, and has since been added to and brought up to date. Mr. PEARSON may be said to have successfully accomplished his undertaking, which was, "not to make a book, but rather to sum up as concisely as possible a few of the facts upon the subject in hand gathered during thirty years of work amongst fruit and fruit trees."

DEFRAUDING THE CHARITABLE.—Messrs. HURST & SON, seed merchants, write as follows :—"In February last we received a piteous appeal from Mr. WM. GADSBY, of 37, Denman Street, Leicester, on behalf of H. W. PARKER (formerly of Huntingdon), seedsman's shopman, who, with his wife and family, were represented to be in most distressed circumstances, and on February 6 we remitted 20*s*. On February 13, upon a further appeal, we remitted Mr. GADSBY an additional 20*s*. On May 14, CHARLOTTE PARKER advised us her brother, HENRY PARKER, had died that morning, after a great deal of suffering, leaving a wife (near her confinement), with several children, and without the means of paying for the funeral, and on May 16 a further remittance of 20*s*. was made, and acknowledged by C. PARKER on May 18. We are now assured that WM. GADSBY and H. W. PARKER are one and the same individual, and that the man H. W. PARKER is still living. We regret that we have been victimised by such false pretences, and with the object of preventing others becoming victims, ask you to kindly give publicity to this letter in your journal.

PLANT PORTRAITS.

BEGONIA, crested form, *Revue Horticole*, June 1.

CATANANCHE CŒRULEA, *Garden*, May 27.

COUNTESS DE TURENNE, hybrid Tea Rose (Bernaix), colour pink, *Rosen Zeitung*, May, 1899.

CEDRUS DEODARA NIVEA.

We owe to the kindness of the Earl of Annesley the following note, accompanied by a photograph, relating to Cedrus Deodara nivea (fig. 146):—"Cedrus Deodara nivea is very beautiful now, being nearly as white as its name applies. We have in the gardens here another Deodar, known as albo-spica, the young foliage of which comes out green, and only turns white as it completes its growth." *Annesley.*

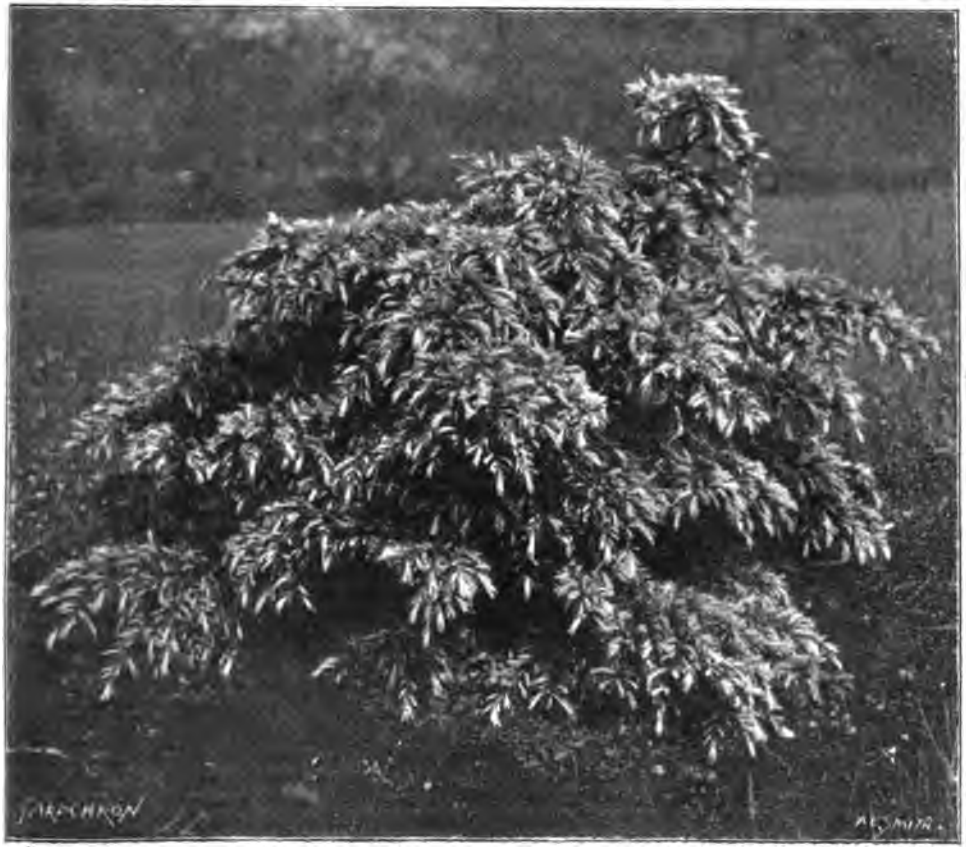

Fig. 146.—Lord Annesley's Cedrus Deodara, Growing at Castlewellan, Co. Down.

NOTICES OF BOOKS.

FACTS FOR FRUIT-GROWERS AND OTHER HORTICULTURISTS.

In the *Agricultural Year-Book of the United States Government*, which has just reached us, are some papers which are of considerable interest to the horticulturist generally. Such contributions as the one on insects which attack the tobacco-plant do not bear very much upon plant-culture in this country, but the article on the "Pruning of trees and other Plants," by William Saunders, contains many valuable observations. A few lines at the beginning, which strike as it were a note of warning, may very well be quoted:—"Plants left to Nature maintain a reciprocal action between the branches and the roots, and every branch and leaf removed must exert an influence either injurious or beneficial; therefore no one should remove a branch until satisfied of a reason for doing so, and foreseeing the influence and effects of such removal."

Mr. Saunders goes on to say that many fruit-growers think that most uniform and satisfactory crops are produced when little or no pruning is resorted to. Vicious and unnecessary pruning, he allows, brings about untold injuries, but he strongly brings out the errors of going to the opposite extreme, and of not pruning at all. To go into more detail, judicious thinning and arrest of unruly and misplaced shoots are to be commended, while making it part of the annual routine to visit an orchard to saw off branches and tops of shoots, without a special object in view, will soon diminish the crop of fruit.

When discussing the season for pruning, it is pointed out in the paper that when the operation is conducted in the early autumn, additional vigour is given to the branches retained. The reason advanced does not seem to be quite so accurate as the fact, according to the generally accepted ideas of the physiology of deciduous trees. It is stated that the improvement is due to the trees continuing "to absorb nutriment by their roots" during the winter. It is hardly necessary to recall the fact that it is the leaves that make the reserve food, taking carbon from the air, and utilising materials sent up by the roots. In winter these manufacturers are gone, and the flow of water from root to leaf has ceased. Even allowing, for argument sake, that the sap still rises into the bare stems, the earth, salts and water of which it is composed, would not be such "nutriment" as would increase the vigour of the branches.

A better explanation would appear to be that the legacy of food stored in the older branches has to be divided among a smaller family of younger ones, which it must be said is practically what Mr. Saunders maintains in the case of buds.

The "flow of sap," or perhaps here it would be better to say the supply of food, is always directed towards the tips of branches, and an accumulation takes place before the winter with the result that terminal buds are the larger ones. The same thing happens in spring with regard to the ends of shoots, and it is pointed out that accumulated food is lost by spring pruning. Perhaps, however, the idea that additions are sent up from the roots in winter may have led to the emphasising of the objection to the previously mentioned process.

Some advice based upon forty years' experience is given us as to the necessity of promptly removing immature wood that the frost may have killed, as this, it is said, is a common source of disease to fruit-trees.

Next, Mr. Saunders sets up the line, which runs:—"Prune in summer for fruit, and in winter for wood;" and proceeds to make an Aunt Sally of it. After considering the principle that checking growth induces the formation of flowers, upon which the first piece of the supposed good advice depends, he points out its uncertain application in the case of summer pruning, and gives a noteworthy example.

"If the growing shoots of an Apple or Pear tree are checked on their extension by removing a portion of their points, say, toward the latter part of June, the lower buds on the shoots will be forced into growth, thus forming numerous side branches, which have no immediate connection with fruiting-spurs, and which simply tend to a further thicket of twigs for removal in winter. But if the shoots are not checked in their extension until August, and the weather afterwards continues to be warm and dry, the probabilities are that the lower buds on these shoots will start into rather feeble side-growth, or short, spur-like shoots, which will ultimately furnish fruiting-buds. If, on the other hand, the season happens to be wet, and mild weather prevails until close to winter, these same side-shoots will lengthen into slender twigs, which will not thoroughly mature, and which will be of no use whatever. The difficulty in reaching successful results lies in the uncertainty as to the proper time to prune, because no two seasons are exactly alike, and also because trees vary in their vigour from year to year. Yet upon this uncertain, indefinite, and constantly experimental procedure is founded the advice, 'Prune in summer for fruit.'"

Of the second half of the rule, short work is made. Mr. Saunders cannot question, of course, that additional vigour is given to fewer buds that remain after winter-pruning, but he very much doubts whether a greater aggregate of wood results, and concludes that to consider that winter-pruning as a practical rule increases the quantity of timber is a fallacy.

Perhaps the most important point in the article is the favour with which the writer of it regards "pinching" and "disbudding." He says that these are the most rational modes of directing the growth of plants, and if rigidly practised, they would do away with the necessity for the removal of branches of any size at any time. The inconsistency of allowing a tree to produce wood in summer, only to have it removed in winter, is brought forcibly before us. The balance of growth, which it is so important not to disturb, remains unaltered, and there is much less labour required to rub off a bud in spring than to cut off a branch in autumn.

After this, we are given hints as to the pruning of roots, and the necessary curtailing of branches at the time of transplanting, as well as instructions for training a hedge. Even the pruning of street trees comes in for attention, and the ideal shape for withstanding sudden bursts of wind is discussed. This is naturally acquired by very few deciduous trees, and is practically that of a Fir, with central stem and leading shoots. Training for positions in the streets should be begun early in the nursery.

Finally, details are entered into with regard to special cases of interest to the fruit-grower. Particular instructions are forthcoming in connection with the culture of the Vine, the method advised being one on which a new leading shoot is taken up annually from the base of the plant, and the old canes removed when they have seen three or four years' service.

Another contributor, Mr. M. B. Waite, gives the result of researches upon the "Pollination of Pomaceous Fruits." It is found that, as is common with other plants, the Apple and Pear have a strong tendency to self-sterility, which means that pollen from one flower does not readily "set" another when both are situated upon the same tree; as also specimens of the same horticultural variation are formed from grafts that originally came from a single tree, and are practically one plant, the same remarks apply. On the other hand, distinct varieties that can be traced back to different seeds cross freely.

The size and shape of fruit following such cross-fertilisation are found to be greatly improved, whereas self-pollinated Pears are practically seedless, and of small proportions.

It must, however, be borne in mind that the sterility is dependent somewhat upon climate, weather, and condition of the trees, but even where varieties are usually self-fertile, the largest fruits are obtained by cross-pollination. Apples are even more markedly self-sterile than Pears, whereas Quinces do not follow this rule at all.

To ensure cross-fertilisation in orchards, the following suggestions are made:—

1. Several varieties should be used, and even if one kind is desired, every third tree in every third or fourth row should be of a different one.

2. When large series of trees have blossomed well for several years and have failed to produce a crop of fruit without any apparent reason, graft in some other varieties.

3. Be sure that plenty of bees are in the neighbourhood, or at least within two or three miles, and endeavour to favour them by selecting sheltered situations, and erecting wind-breaks.

Other information, useful to the fruit-grower, is to be gained from an article upon "Utilising Surplus Fruits," while much suggestive and readable matter for gardeners is included under such titles as "Birds as Weed Destroyers," "Insects Injurious to Peas and Beans," and "Improvement of Plants by Selection," not to mention "Grass-seed and its Impurities," and several others dealing with soils. *Wilfred Mark Webb.*

THE FLORA OF CHESHIRE.—By the late Lord de Tabley. Edited by Spencer Moore, with a biographical notice of the author by Sir Mountstuart Grant Duff (Longmans).

BOTANISTS had long to wait for the *Flora of Kent*, which we noticed in a recent issue, and a similar exercise of patience has been imposed upon them in the case of the *Cheshire Flora*. Those who knew the accomplished author of the last-named work will experience no surprise at the delay in publication. Rather will they feel their obligations to Lady Leighton, to whose pious care it is that we owe this valuable addition to the botanical history of our country. This lady, in arranging her brother's papers, lighted on two MSS. relating to the Cheshire flora, of which the latest in date, completed some twenty-five years since, forms the substance of the present volume. The editorship has been entrusted to Mr. Spencer Moore, and carefully and well has he executed his trust.

The biographical notice supplied by Sir Mountstuart Grant Duff is a charming piece of writing, and the introduction of some of Mr. Warren's poetry, is a delightful innovation in a technical flora. Let us hasten to say, it is only tolerable when as good in quality as the samples here provided. For the Hon. Leicester Warren, to use the name by which he was best known, was a poet by nature, and a man of culture and wide sympathies. "Studies in verse," novels, treatises on book-plates and on Greek coinage give evidence of this.

In botany he was not attracted by the merely sensuous side of the subject, for Brambles and Docks were two of the genera that he most affected, and no inconsiderable amount of enthusiasm must be expended to study these plants as Warren did.

A short account is given of the county of Cheshire, and of the districts into which it may be divided from a botanical point of view. To estimate the value of this necessitates a personal acquaintance with the county. In the list of "Persons concerned in the past with Cheshire Botany," we find the name of Henry Shepherd, the curator of the Liverpool Botanic Garden, and the first in this country to raise Ferns from their spores. More recent contributors to the *Cheshire Flora* are E. M. Baillie, C. Wolley Dod, Leo Grindon, and many others. The Flora itself is enriched with numerous notes, so that the volume will not only be indispensable to Cheshire botanists, but a valuable book of reference to those concerned with British plants in general. A map and a good index render it all the more serviceable.

HOME CORRESPONDENCE.

LEEKS.—One of the things I have found out here is that the Welshmen in this primitive place do not regard the Leek as a national plant. It certainly is not usually grown in gardens, and I have seen it grown properly only in one garden —where the head gardener is an Englishman. *E. W. B., Clynnog.*

THE PARADISE STOCK.—Your correspondent, "D. T. F.," seems to assume that the employment of the Paradise stock is of quite recent origin. Certainly, even in the '50's, not much was heard about it in gardens; but old John Rogers, whose *Fruit Cultivator* is one of the best of the old fruit books, refers to the Paradise stock as being in common use some time anterior to the date of publication, viz., 1834, and that was sixty-five years ago. Referring to this stock, he says:—"By all accounts, it is of Dutch origin, but first found its way into England through travel." It has, however, been long ago proved by Mr. Grey, of the Fulham nursery, that the French is inferior to the Dutch Paradise stock, especially for espaliers. That the French Paradise stock is a more than dwarfing stock—that *is*, a cramping and almost a strangling stock, we have long known. It therefore seems evident that the stock then described as the Dutch Paradise is identical with that now known, and so abundantly used, as the English or broad-leaved Paradise. The author mentions that these stocks can be obtained from abroad (as now) with great facility; also that they do best on a somewhat moist rather than a dry soil. Of the long list of varieties of Apples given in the book, many of which have gone out of cultivation, several are recommended as best suited for diverse forms of culture, when worked on the Paradise stock. All this goes to show that its employment in nurseries must have been well known and common, doubtless, from 75 to 80 years since. Our horticultural records are, in these matters, none too clear, as then we had no regular horticultural press. Now it is but needful for the horticultural historian to turn up the columns of the *Gardeners' Chronicle*, or its contemporaries, and information on almost everything will be found. *A. D.*

ELŒOCARPUS CYANEUS.—The pleasing, small, pure white, bell-shaped, deeply fringed flowers of this Australian shrub are produced in racemes that arise in the axils of the leaves. The flowers are succeeded by blue-coloured berries about the size of those of the Sloe. In its native country it grows to a height of 15 feet, and in this country it forms an excellent subject for planting in borders in large conservatories. A plant is now in flower here at the Botanic Gardens, Liverpool. *J. G.*

ADVERTISEMENTS.—In the *Gardeners' Chronicle* of June 10, there is an advertisement: "Wanted, a head gardener for a large garden, with a man and a boy under him." And I assume from the amount of assistance given, that he has about three acres of garden ground, with or without a cow, and I should hope not much glass. He wants a hard worker, which most gardeners have to be; but the sting is at the end of his advertisement, where he says that he does not want a suburban or southern counties gardener. I think, that had he said he wanted an honest God-fearing man, who knew his business, he would have got what he wanted, and concealed his ignorance. Southern counties is a comprehensive word, and our Scotch friends "come down south" to get the finishing touch to their education, and we are pleased to see them, and moreover in the southern counties horticulture is more advanced than in any part of the world. The day of parochialism is over, north-south-east and west are amalgamated. We are all members of one great Empire, all necessary with our respective good and bad qualities alike, for the maintenance of our common heritage, so that any comparisons shows a want of comprehension of things as they now exist. *R. M., Newbury.*

MILDEW ON VINES.—Respecting the discussion on the subject of destroying mildew on Vines, I should have some hesitation in using boiling-water on Vines in the early stage of their growth, although I have no reason to doubt Mr. Mallett's statement. My experience of the use of hot water as an insecticide is, that it is quite safe to syringe with at about 130° in the destruction of all insects, but not beyond; as, having tested it at that degree of heat on forced Roses they came out all right. In using water at 150° to 160° I found that all the young growths and tender foliage turned black. I would not advise even water at 130° to be used on tender greenhouse plants or Ferns, but rather a few degrees less, which will be found equally effective, and not injurious to the plants. The following, a simple recipe, I have found an unfailing remedy for mildew on Roses in pots, and it would most likely be equally as efficient on Vines, and that without any injury accruing to the foliage. Mix thoroughly 1 lb. of sulphur vivum or black sulphur with 1 lb. of soft-soap, and when thoroughly dissolved paint the hot-water pipes with the mixture, and I guarantee every vestige of mildew will disappear after two or three applications, and prove far more effective than a good many of the remedies for mildew now on the market. *J. D. Godwin.*

—— In reply to "R. M." in last week's issue of the *Gardeners' Chronicle*, p. 383, I may state that the Grapes were in two stages when the hot-water remedy was applied; those in one house were about the size of Marrowfat Peas, those in the other were smaller, scarcely larger than seeds of Sweet Peas. *Geo. B. Mallett.*

RHUBARB AS SPINACH.—The *Gardeners' Chronicle* for May 27 is at hand this morning, and the note on "Rhubarb Leaves as a Vegetable," prompts me to say to you that instances have been known here where their use as "Greens" has caused fatal results, owing to the excess of oxalic acid. A horticultural friend told me many years ago that he had raised many seedlings, some of which (I assume that the usual part was cooked in the usual way), caused vomiting as certainly as ipecacuanha. *Robert Manning, Sec., Mass. Hort. S*

A QUESTION.—Thinking of a few of some of the garden plants of fifty years ago, that were more worthy of our attention than those grown now-a-days, but which seem lost to gardens and unknown on enquiry of the trade, where is the old double black-flowered Delphinium, just the colour of the black Hyacinth? Where also are the old double Wallflowers, brown, ginger, black, purple, and yellow coloured? They have not been seen by me for many years. The beautiful yellow Violet, not the plant called now Pansy-like, but the shape of an ordinary Violet, sent out by the late Mr. J. Veitch about forty-five years ago. Where also are the Hyacinths double purple-green tips, double red-green tips, and double white-green tips? I never see them offered by anyone in the trade now. I used to grow them; the red and the white I used to obtain of the late Mr. John Sutton. A few days ago that and the purple of the Rev. J. Tyso, and many other things too numerous to name just now from memory. Also the "Midsummer Men and Maidens" [Sedum Telephium, a common plant. ED.]. I believe it produces milk [No], like an Euphorbia, but I have never been able to get it. *J. C.*

TEMPERANCE DRINKS FOR THE HARVEST FIELD.—The Church of England Temperance Society has, for some time, been endeavouring to popularise the use of cheap, easily-made drinks for use in the harvest-field, hop-garden, workshop, and laundry. For this purpose the executive has taken Stall No. 59 at the Royal Agricultural Shows Maidstone, from June 17 to 23, and at the South Eastern Show, Tunbridge Wells, from July 19 to 21. Here we hope to make simple drinks suitable for the table, the field, or the workshop, and to give recipes and samples to visitors. We do not claim to be able to revolutionise our drinking customs by this means, but we do claim to show how thirst-quenching, nourishing, and exceedingly palatable beverages may be made with little more trouble than tea or coffee, at an expenditure of 2*d.* to 4*d.* per gallon, and from articles easily obtainable. May we, through your columns, invite your readers to call at our stall to see and taste for themselves, or to write to me for the recipes which we shall be most happy to send? *George B. Charles, Clerical Secretary, Canterbury Diocesan, C. E. T. S., 94, Oakfield Road, Croydon, June* 10.

KILLING AMERICAN BLIGHT, ETC., BY FIRE.—I should feel pleased if you would make known in your valuable *Gardeners' Chronicle*, the means I have adopted to destroy, not only the American-blight, but also their eggs, however numerous they may be, without in the least injuring the Apple-trees. About forty years ago I planted several Blenheim Apple-trees, and since that time several young ones of the same sort, on all of which these pests have been gaining ground; and although I have tried all the means I could hear of, or read of, I could only check their ravages for a time. The trees have been sadly disfigured, and some branches literally killed. But a week ago I thought of some new plan (to me), most easy; although hot and severe, it was perfectly powerful to exterminate them. I hired a painter's lamp for 3*d.* only, charged it with benzoline (2*d.* per pint), and when lighted, having the flame reduced to a minimum by the screw. I had simply to direct the flame about 3 inches distant from the nests of the blight; in a second the woolly appearance melted away, and the creatures fell to the ground dead and dried up, also the eggs destroyed. The heat was only for an instant, so that the trees, and even the small twigs, were perfectly safe. I am very glad to name this for the benefit of all growers of these splendid Apples. *Wm. Moody Bell.*

CONTINENTAL NOVELTIES.

ROSE MADAME WAGRAM COMTESSE DE TURENNE.

THIS is a novelty raised by M. Bernaix in 1894, and ranked by him as a Tea Rose, although in describing it he says it is "a big Tea Rose with H. P. blood in it." It is certainly a large Rose, of globular shape, very double, and with broad petals. The flower-bud is egg-shaped, has great substance, and surmounts an erect stiff stalk. The bloom has a certain resemblance to Merveille de Lyon, and measures from 4½ to 5½ inches in diameter, opens freely, and keeps a long time in good condition as well on the plant as when cut. The colour is a fresh, silky salmon-pink, changing to flesh-pink and china rose, with a silvery tinge over the entire flower, and the edges of the petals appear white.

The plant is very vigorous, bushy in habit, but not compact, and possesses more of the character of a hybrid Tea than of a Tea Rose. The name will have to be shortened to Madame Wagram, being altogether too long for present day use. The novelty is a good Rose for exhibiting, and for the florist's work; but before the public will take to it, it must like other novelties be frequently exhibited. A coloured plate of the variety appears in the May issue of the *Rosen-Zeitung.*

DOUBLE ZONAL PELARGONIUM GLOIRE DE FRANCE.

This is probably one of M. Victor Lemoine's raising, and is certainly one of the most attractive decorative varieties I have seen. The central colour is bright orange-carmine, and the well-formed petals are distinctly edged with white. It is of a shade of colour that appears to be very popular in these days, and Mr. Arthur Turner, who called my attention to it at the Royal Nursery, Slough, said they had used this variety largely for decorative purposes both at Ascot and Windsor. The trusses, borne well above the foliage, are large and symmetrical, and the leaves darkly zonate. I cannot so far find this variety in any list under this name, but those who grow zonal Pelargoniums for decorative purposes will do well to add it to their collections. *R. D.*

NEW INVENTIONS.

WE have received a sample of several very simple devices for rendering more convenient the work of securing plants to stakes and to walls. These "S. M." Fasteners are made of soft, consequently very pliable lead, with holes at each end. By using ordinary nails, these convenient tree-fasteners should last a considerable time. Clips are made of the same material, and are intended for use instead of any tying material, for securing plants to stakes. The Leeds Orchid Company, who manufacture the above articles, also send a sample of a permanent shading, in a condition ready for use, and of their "Ivorine" plant labels, with indelible ink for writing thereon. For many purposes these ivory-coloured labels would be most useful, as they possess the quality of neatness in a marked degree.

THE "ABOL" SYRINGE.

New insecticides and appliances for their distribution abound at the present day, rendering the choice of one or the other exceedingly difficult to the inexperienced. We have lately received from Messrs. E. A. White, Limited, Hop and Fruit-growers, Paddock Wood, Kent, a handy, well-constructed brass syringe, intended to economically and efficiently distribute as a fine spray clean water, or liquid insecticides, over fruit-trees and bushes, &c. It is fitted with a drip-preventer, and also a detachable elbow-joint, to enable the undersides of the foliage to be more easily reached by the operator than is possible with an ordinary syringe when the plants operated upon are of low growth; as, for example, Strawberry-plants, Gooseberry, Currant, and Rose-bushes.

Obituary.

THOMAS J. SALTMARSH.—The death of Mr. Thomas Joseph Saltmarsh, the head of the firm of Messrs. Saltmarsh & Son, the Nurseries, Chelmsford, took place on the 2nd inst. at the age of seventy-two. He had been in failing health for some time past, and in consequence was rarely seen at the meetings of the Royal Horticultural Society, although a member of the Fruit Committee. In the latter part of the week, previous to his death, Mr. Saltmarsh was seized with a paralytic fit, and passed away without recovering consciousness. He leaves a widow, but no children. The nurseries, up to the death of Mr. Saltmarsh, had been in the possession of three generations of the family. They were founded in the latter part of last century, by the grandfather of Mr. T. J. Saltmarsh, who died in 1829, when the father of the latter, Mr. Joseph Saltmarsh, succeeded, and carried on the business until 1872, when the son just deceased became manager, and succeeded to the estate. Mr. T. J. Saltmarsh in early life was sent to the Pineapple Place Nurseries, in the Edgware Road, where he remained for two years, and then returned to Chelmsford, to assist his father in the business. The firm has enjoyed for years an excellent county reputation, and a general collection of nursery stuff was grown by them. The rearing of Mulberries was at one time a leading specialty. For some years a great deal of exhibiting was done; fine specimens of show and zonal Pelargoniums, Dahlias, Asters, Chrysanthemums, fruit, &c., being grown for the purpose. In reference to the last-named, it will be remembered that two fine and popular kitchen Apples, the Queen, an October variety, and Chelmsford Wonder, December to March, both of which received first-class certificates from the Royal Horticultural Society. He was at one time particularly successful with Chrysanthemums as an exhibitor, winning many medals and also several silver cups. He was a supporter of several of the special floricultural societies, and a frequent attendant at their exhibitions. At Moulsham, a suburb of Chelmsford, in which the home nursery is situated, Mr. Saltmarsh was an active public man, and will be greatly missed. He filled the post of vicar's churchwarden at Moulsford, and warmly supported all educational efforts. As a judge at flower-shows he was in much request; of modest and retiring habits, there was an entire absence of self-assertion. In all that he undertook the ruling motive with him was the best interests of those about him. He was interred in the borough cemetery, Chelmsford, on the 7th inst., amid many manifestations of respect and regret.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 13.—The first ordinary meeting of the Committees, following upon the Temple Show, was held in the Drill Hall, Westminster, on Tuesday last, and was attended by an exhibition of considerable extent. In the first place, there was a fine display of Orchids, and there were awarded to novelties of this description one First-class Certificate, four Botanical Certificates, and six Awards of Merit.

Then there were many grand exhibits of hardy flowers; some of the visitors ventured the remark that it was quite an "Iris" day, there being very extensive collections of German and Spanish Irises from Messrs. JAS. VEITCH & SONS, Messrs. WALLACE & Co., Mr. PRITCHARD, and others. But the meeting was equally remarkable for Carnations, and the Floral Committee was engaged more than usually long in adjudging the merits of novelties, most of which were Carnations. The Floral Committee's awards were eight Awards of Merit to Carnations, two to Roses, one to a Rhododendron, and one to a variety of Lupinus arboreus. The Fruit Committee made no award to a novelty.

In the afternoon there were elected to the Society upwards of eighty new Fellows; and Mr. Meyer, of Exeter, read a paper upon "Rock Gardens, Ponds, and Rivulets in Gardens," in which practical suggestions were given upon the formation of rockeries, with a view to producing the most natural results. The choice of plants, and the planting of them, were also subjects that were very fully explained.

Among the visitors to the Drill Hall was Mr. Arderne, of Cape Town, South Africa, from whose remarkable garden there we have frequently been favoured with interesting photographs, several of which have been reproduced in these pages. Mr. Arderne was invited to a seat upon the Floral Committee.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. H. M. Arderne (South Africa), S. A. de Graaff, Chas. T. Druery, H. B. May, R. Dean, W. Howe, J. Jennings, Jas. Hudson, C. J. Salter, J. D. Pawle, W. Bain, Chas. Jeffries, Jas Walker, George Gordon, Chas. E. Shea, Jas. H. Barr, E. T. Cook, Herbert J. Cutbush, Ed. Beckett, Harry Turner, C. Blick, E. H. Jenkins, Geo. Paul, H. J. Jones, H. Selfe-Leonard, Ed. Mawley, and J. Fraser.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, made a large display of trusses of Rhododendron blooms in an exhibit that included a few choice alpine plants and bunches of garden varieties of Roses and Sweet Briars. The bold trusses of Rhododendron exhibited a number of varieties of bright and distinct colours. Messrs. PAUL also showed blooms of a very pretty hybrid Bourbon Rose named J. B. M. Camm. It is exceedingly pretty in form, and pink and rose in colour. Rhododendron Fortunei Boadicea is a large handsome variety with purple flowers, with throat spotted and marked with brown (Silver Banksian Medal).

Messrs. GEO. JACKMAN & SON, Woking Nursery, Surrey, contributed a most gay exhibit of hardy flowers, in which single and double-flowered varieties of Pyrethrum roseum were conspicuous. There were fine bunches of the yellow-flowered Lupinus arboreus, Tritonia caulescens, T. Tucki, Irises of sorts, Senecio Doronicum, rich orange colour; also a number of bunches of choice varieties of Lord Penzance's hybrid Sweet Briars, Lord Penzance and Lady Penzance, the former orange and flesh coloured, and the latter rich rose with orange centre, are amongst the earliest and most distinct. Other large and handsome varieties were Amy Robsart, Julia Mannering, Green Mantle, Lucy Bertram, Jeannie Deans, Blush China, &c. The firm also staged a small lot of flowers of hardy herbaceous perennials and hardy deciduous shrubs. Of the former, we noticed Aster alpinus superbus, with lilac-coloured rays and a yellow disc; Sidalcea malvæflora, a plant with compact short spikes, furnished with numerous crimson flowers, which open in long succession; Papaver Blush Queen, flowers single, of a dull pink tint, with a red-purple patch at the bottom of the flower; Betonica grandiflora, &c. Of shrubs, there were Hedysarum multijugum, Baptisia australis, and Weigela Eon Rathke, a dark crimson flower (Bronze Banksian Medal).

Messrs. R. Wallace & Co., Kilnfield Gardens, Colchester, had a group of choice hardy plants and flowers, varieties of Lilium Thunbergianum, such as atro-sanguineum, marmoratum, and testaceum, were shown in pots. There were cut flowers of Lilium rubellum, Anthericum liliastrum major, plants of Cypripedium spectabile, many sorts of Iris, Brodiæa capitata (blue), B. Howellii lilacina, B. coccinea, B. laxa (blue), Ixiolirion Pallasii, and the deepest coloured blooms of Incarvillea Delavayi we have yet seen. A few of the smaller flowered Calochorti, including amœnus albus, pulchellus, &c., were included (Silver Banksian Medal).

Messrs. James Veitch & Sons, Royal Exotic Nurseries, Chelsea, made a very remarkable exhibit of varieties of German Irises, and although there is nothing particularly new to notice in the collection, it was a fine exhibit of the choicest varieties obtainable in the section, in addition to being one of the most attractive exhibits in the hall. It would serve no useful purpose to mention a number of these varieties that have been described in the trade catalogues, but those of the Pallida section, and such others as Duc de Brabant, Prince of Orange, Shakespeare, Sans Souci, flavescens, A. F. Barron, Madame Chereau, and others were some of those giving the greatest effect. A dozen or so varieties of the Spanish Iris were also very pretty, and a number of bunches of Ixias from pot plants splendidly illustrated the beauty of these Cape bulbous flowers when well and strongly grown (Silver Banksian Medal).

This firm also showed some plants of Pharus guianeensis albo-striata, a variety differing from the type in having considerable variegation in the leaves. This, like the type, has been introduced, and it will likely become a popular decorative plant. Also blooming a number of varieties of their Javanico-jasminiflorum hybrids of Rhododendron, so remarkable for the beautiful colours they present, and for their handsome appearance.

Mr. H. T. Martin, gr. to Lord Leigh, Stoneleigh Abbey, Kenilworth, showed a group of rather small but pretty plants of Abutilon Sawitzii. This pretty variegated plant was the subject of a note by Mr. Martin on p. 276 of the *Gardeners' Chronicle* for May 6.

Messrs. F. Sander & Co., St. Albans, had a group of foliage-plants, in which were included most of the new species frequently exhibited by this firm, most of which have been described in these pages. Acalypha hispida, Dracæna Sanderiana, Linospadix Micholitzii, Panax Mastersianus, Juniperus Sanderi, Mikania Sanderi, Cyperus fertilis, Dipladenia Sanderi, and several varieties of Caladiums, were noticed (Silver Banksian Medal).

Mr. F. Cant, Braiswick Nursery, Colchester, staged a large quantity of "Garden Roses," Lord Penzance and other Briars; yellow and other Scotch Roses, common China, in several varieties; and such Roses as the Austrian Copper, Mignonette, R. rugosa fimbriata, a pale flesh-flower, with prettily-fringed petals of large size, and semi-double — it blooms the entire summer; Crimson Rambler, the new Climbers named after the Three Graces, viz., Aglaia, pale yellow-rose, with a nice small bud, and the fragrance of the Tea-Rose; Thalia has minute semi-double white flowers, with a yellow centre. Both of these varieties are of rampant growth, good for covering arbors, making garlands, festoons, &c. Euphrosyne, the sister-Rose to these two, but which was not shown, has semi-double, bright pink flowers, bringing, as all three do, a long succession of blooms. Dawson is a bright, pink-coloured, new climbing Rose. Other Roses were Marie Pavie, white, with blush centre, and double-flowered; Gustave Regis, beautiful in the bud, which in that stage is reddish-orange; Queen Mab, salmony-orange; R. rugosa var. blanc double de Coulert, a large semi-double white flower of large size when fully expanded; R. inermis, a rose-pink, Perle de Panachées; Mme. Geo. Bruant, white, nice in bud; Marquis of Salisbury, Cooling's single-flowered Crimson Bedder, Armosa (Hermosa ?), a full, compact Rose, light pink in tint; Geo. Pernet, Lavette Messing, a flower beautiful in bud, or when half opened, coppery-pink and orange; Olga de Würtemberg, a big, showy, deep crimson flower, the plant very vigorous; R. rugosa, Souvenir de Pierre Leperdrieux, a big flower of a taking shade of purple (Silver Gilt Flora Medal).

Messrs. G. Cooling & Sons, nurserymen, Bath, showed the new garden Rose Purity, white, with the faintest blush tint in the centre of the unopened bud, and beautiful in that condition (Award of Merit). They showed Cooling's Yellow Noisette, a flower also admirable in the bud state, and apparently a capital bouquet or button-hole Rose (Award of Merit).

Messrs. Young & Sons, nurseryman, Windmill Lane, Cheshunt, showed plants of a white Viola, having flowers of good shape, and possessing a small yellow eye.

Messrs. H. Cannell & Co. exhibited a large group, consisting of the finest varieties of Canna indica. We noted Burbank, one of the finest yellow varieties; Comte de Bouchaud, yellow, regularly dotted with crimson; Duchess of York and Florence Vaughan, similar; Provincial, scarlet; Madame Crozy, &c. The spikes were generally of large size, flowers well developed, and foliage plentiful (Silver Gilt Flora Medal).

Mr. B. Ladhams, The Nurseries, Shirley, near Southampton, showed an extensive assortment of hardy herbaceous perennials as cut bloom, such as we have been accustomed to observe in fine condition and great variety from this nursery for several years past. Pinks in variety were prominent, and the variety Lizzie Duval, a flower of soft purplish-rose was very noticeable; Pyrethrum roseum in many varieties were likewise noticeable for brilliancy of colour; also Dictamnus Fraxinella, Muscari, various; Hemerocallis Dumortieri, a flower deep yellow within, and orange-tinted without, &c.

Messrs. Barr & Sons, King Street, Covent Garden, and Long Ditton, showed a large collection of cut blooms of hardy plants, especially noticeable being Papaver Salmon Queen, Pæonia herbacea, Iris in much variety, Kniphofia Tucki, Alliums, Ixias, &c. (Silver Banksian Medal).

Martin R. Smith, Esq., The Warren, Hayes, Kent (gr., Mr. C. Blick), showed a group of Carnations, receiving a Silver-gilt Medal. Almost the entire collection consisted of Souvenir de la Malmaison, in its varieties of crimson, flesh, blush, pink of different shades, white, crimson, and scarlet; and being grown with one flower per plant they were fine of size. Of ordinary Carnations an Award of Merit was made to Don Carlos, a fancy, with a yellow-coloured ground and crimson edge and stripes, more Picotee than Carnation.

Mr. John Russell, Richmond Nurseries, exhibited a group of tree Ivies with green, silvery, and variously variegated foliage of various heights, including many in standard form. These tree Ivies seem to be finding employment in a variety of ways in the garden, and as they afford a desirable variation in form, height, and colour to the floral occupants of beds and borders, their use is likely to spread (Silver Banksian Medal).

A glorious exhibit of hardy flowers was made by Mr. Maurice Pritchard, Christchurch, Hants, the various bunches of flowers indicating excellent cultivation. Spanish Iris Leander, orange-yellow coloured; and the variety Beauty of Haarlem, with others, were capital. Ixias, Pyrethrums, Lilium umbellatum erectum, Lupinus arboreus, Thalictrum aquilegifolium, Dictamnus Fraxinella albus, &c., were noticed, and fine sprays of Tropæolum Leichtlini, an excellent species for the rockery (Silver Banksian Medal).

Messrs. T. S. Ware, Ltd., Hale Farm Nurseries, Tottenham, also showed a grand exhibit of choice hardy flowers. Of these there were noticed Pyrethrums, Tritonias, Dianthus cæsius, Armeria cephalotes rubra, some of the best blooms of the new Lilium rubellum we have yet seen, the flowers being very large and of pretty form and colour; Geums, Incarvillea Delavayi, Hieracium villosum, &c. (Silver Flora Medal).

Mr. C. Turner, Royal Nurseries, Slough, showed blooms of some choice border Carnations, several of which gained Awards of Merit.

From Mr. F. W. Moore, Glasnevin Botanic Gardens, Dublin, came flowering sprays of Fremontia californica, and Pæonia Emodi, the latter with single, white flowers.

Messrs. Carter & Co., High Holborn, London, contributed a group of well-flowered Gloxinias in pots.

Mr. Mark Fenwick, Meldon Park, Morpeth, showed a device in wire for raising plants in pots, and by means of supporting the plant immediately above a tin dish provided in the stand, and which is filled with water, the plant is protected from slugs and other creeping plant pests.

British Ferns were shown in an extensive group from Mr. H. B. May, Dyson's Road Nursery, Upper Edmonton. This collection, which is the first exhibit composed exclusively of British species we have seen from this establishment, included as many as 140 species and varieties. The genera Athyrium and Lastrea accounted for a large number of the specimens, and the wonderful variations caused much attraction. Mr. May also showed a number of plants of a pretty orange-yellow-flowered Tropæolum, known as Sunlight (Silver Flora Medal).

Ochna multiflora was shown in fruit by J. T. Bennett-Poë, Esq., Holmwood, Cheshunt (gr., Mr. Downes). This is a stove evergreen, that produces yellow flowers, followed by a globular receptacle similar to a Strawberry in shape and colour. On the surface of each highly-coloured receptacle are produced several black seeds, of great contrast to the receptacle.

AWARDS.

Carnation Galileo.—A creamy yellow ground flower, of large size and good form, with deep purple edge. From Mr. C. Turner (Award of Merit).

Carnation Falcon.—A large yellow-coloured flower with slight shades of brown. From Mr. C. Turner (Award of Merit).

Carnation Galatea.—A yellow flower with narrow edge of bright red colour, a very pretty variety, of good form. From Mr. C. Turner (Award of Merit).

Carnation Agnes Sorel.—A handsome and refined flower of large size, colour deep maroon. From Mr. C. Turner (Award of Merit).

Carnation Goldfinch.—A pure canary yellow-coloured border Carnation of much merit. From Mr. C. Turner (Award of Merit).

Carnation Ossian.—A tri-coloured flower flaked variously with maroon and rose on deep purple ground. From Mr. C. Turner (Award of Merit).

Carnation Don Carlos.—A fine yellow-ground border Carnation with narrow rose edging, a very fine flower of pleasing form. From Martin R. Smith, Esq. (Award of Merit).

Carnation Lady Rose.—A Malmaison Carnation of peculiar shade of pink, distinct and attractive. From Martin R. Smith, Esq. (Award of Merit).

Carnation Florizel. — Another distinct variety of the Malmaison type, colour rosy carmine. From Martin R. Smith, Esq. (Award of Merit).

Lupinus arboreus albus "Snow Queen."—A white flowered variety of this well-known and popular Lupin. It should be a most effective plant. From Mr. B. Ladhams, Shirley Nurseries, Southampton (Award of Merit).

Rhododendron Essex Scarlet. — A richly-coloured flower, spotted upon the upper segments. From Messrs. Paul & Son (Award of Merit).

Rose Purity.—A garden Rose of moderate size, very pretty in bud and when more developed, slightly fragrant and pure white in colour. From Geo. Cooling & Son, Bath (Award of Merit).

Rose, Cooling's Yellow Noisette.—The flowers are a pretty shade of yellow, very attractive, but rather thin; as the flower becomes expanded; the foliage is large, smooth, and olive-green in colour. From Geo. Cooling & Son, Bath (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshay, H. Little, J. Gabriel, A. H. Smee, F. Sander, H. J. Chapman, A. Outram, E. Ashworth, T. W. Bond, J. Colman, J. Gurney Fowler, F. Mason, W. H. Young, H. T. Pitt, S. Courtauld; and by invitation, Hugh Dixson, of Sumner Hill, New South Wales.

There was an exceptionally fine show of Orchids, the grand group staged by Messrs. Jas. Veitch & Sons, Chelsea, and which secured the Award of a Gold Medal, being one of the most remarkable exhibits of the year. Prominent among the many showy hybrids in it were several fine forms of Lælio-Cattleya × Aphrodite and L.-C. × Canhamiana, two of the handsomest Orchids of the season, and supplying interesting variations. Among the newer hybrids not previously awarded certificates were Lælio-Cattleya × Lucilia and Epidendrum × Langleyense (Pseud-epidendrum × Wallisi), both of which secured Awards of Merit. Among the forms of Lælio-Cattleya × Aphrodite, the variety 'alba' with white sepals and petals, was very handsome; Lælio-Cattleya × Wellsiana albida, L.-C. × Hippolyta, forms of Epidendrum × O'Brienianum, of varied colour; E. × elegantulum, and its yellow variety 'luteum'; Masdevallia × Curlei, Cattleya × Schroderiana, Epiphronitis × Veitchi, the charming Spathoglottis × aureo-Veillardi, Lælia × Latona, a good show of Disa × Veitchi, Phalænopsis × Ludde-violacea, &c.; while among the species and varieties were noted a fine set of Lælia purpurata, Cattleya Mossiæ, C. Mendeli, a grand pan of Masdevallia Veitchiana grandiflora, Sobralia macrantha alba; good examples of Trichopilia crispa marginata now become very rare; Phaius bicolor purpurea, Miltonia Phalænopsis, M. Roezli, and M. vexillaria, Angræcum modestum, Cœlogyne Dayana, and numerous Oncidiums and Odontoglossums.

Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), staged an interesting group, which showed the wide variation in Cattleya Mendeli, viz., C. M. alba, a charming white flower with a slight blush tint; C. M. Nellie Wigan, a still more beautiful white form with pale rose tinge on the lip; and C. M. Model, a dark form, with rich, ruby-red front to the lip. The forms of Miltonia vexillaria, too, were equally interesting, and ranged from the white M. v. alba to the noble M. v. Memoria G. D. Owen, with its dark mask of rich claret-colour on the lip (Cultural Commendation). Also in the group were a series of fine varieties of Cattleya Mossiæ, the best form of C. M. Reineckiana being among them. Some good Cypripedium Curtisii, C. × Gertrude Hollington; a nice specimen of Epidendrum atropurpureum; good Lælia purpurata, Odontoglossum × elegantius, &c. (Silver-gilt Flora Medal).

De B. Crawshay, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), was awarded a Silver Banksian Medal for a group of Odontoglossum crispum, remarkable not only for the fine quality of the flowers, but also for their remarkable culture, evidence of which was especially given by one fine plump plant, bearing a large seed-capsule on the last year's bulb, while the one since perfected bore two strong flower-spikes. Among the finest were O. crispum "White Empress," and O. c. "Princess May," both noble white flowers, the latter tinted rose.

J. Bradshaw, Esq., The Grange, Southgate (gr., Mr. Whiffen), secured a Silver Banksian Medal for an effective group, in which the fine forms of large-flowered Cattleyas were remarkable. Cattleya Mossiæ "Admiral Bradshaw" was a very handsome form; C. M. "Mrs. J. Bradshaw," a noble flower, very rich in colour and fine in shape; C. M. alba and C. M. Reineckiana, two good whites. Also noteworthy were the pure white Cattleya intermedia alba, C. Mendeli "Venus," a chastely beautiful form; Lælio-Cattleya × Aphrodite, some very good Odontoglossum crispum and Lælia purpurata; Cattleya labiata Warneri, Dendrobium Jamesianum, Epidendrum vitellinum, Lycaste Deppei, &c.

Messrs. Hugh Low & Co., Enfield, staged a good group, principally composed of their grand strain of Cattleya Mossiæ, the darker varieties of which were very richly coloured, one having a labellum which seemed to imitate Cattleya Hardyana. The forms of C. Mendeli were equally good, C. M. Lowiæ being a lovely white variety. Present also were good Odontoglossum crispum, Aërides Houllettianum, Epidendrum prismatocarpum, Lælia flava, and other showy species (Silver Banksian Medal).

Messrs. Stanley-Mobbs & Ashton, Southgate, were awarded a Silver Banksian Medal for a pretty group, in which were good Cattleya Mossiæ, C. M. Mrs. C. H. Firling being very fine in form and colour. Also included were good varieties of Lælia tenebrosa, Cattleya Schilleriana, Odontoglossums, Oncidiums, &c.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr., Mr. Davis), showed Lælia purpurata "Rex," a very fine flower; Lælio-Cattleya × Aphrodite, Glebelands variety, one of the best coloured forms yet shown; C. Mossiæ, Glebelands variety, resembling Reineckiana, but with a bluish tint on the lip, and other Cattleyas.

Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. Wm. Murray), showed Lælio-Cattleya C. G. Roebling, Cookson's variety (C. Gaskelliana × L. purpurata), a showy, pale rose flower, with purplish-mauve front to the lip. W. P. Burkinshaw, Esq., Hessle, Hull (gr., Mr. Barker), showed

Lælio-Cattleya × Canhamiana, var. Amelia, a very fine rose-coloured flower, with velvety ruby-red lip.

Baron Sir H. Schroder, The Dell, Staines (gr., Mr. H. Ballantine), showed Phalænopsis × John Seden (amabilis ♀, Luddemanniana ♂), with pretty rose-coloured, densely spotted flowers.

Mr. R. D. Leech, The Gardens, Wood Hall, Dulwich, secured a Cultural Commendation for a large and finely flowered Epidendrum Wallisii. Messrs. Jas. McBean & Sons, Cooksbridge, showed Cattleya Mendeli Protheroeana, a very beautiful white flower, with slight rose mark on the lip; the flower finely formed, and the lip closely crimped at the edge. Mr. W. Bolton, Wilderspool, Warrington, showed Cattleya Mendeli Blue Queen, a very pretty, light form, with a decided blue tint on the lip.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed Lælia tenebrosa Pittiana, a very distinct light-coloured form; Zygopetalum citrinum, and Cattleya Forbesii. H. F. Simonds, Esq., Woodthorpe, Beckenham (gr., Mr. G. E. Day), showed Lælia purpurata Simondsii, a very large flower, with fine claret-purple lip. F. W. Moore, Esq., Director of the Botanic Gardens, Glasnevin, Dublin, sent Eulophia guineensis and Epidendrum porphyreum.

R. G. Fletcher, Esq., Mount Harry, Brighton, showed Odontoglossum × Adrianæ Florence Fletcher, a large and finely-spotted flower; and O. c. Brighton Beauty, a rose-tinted form. Mr. T. Rochford, Broxbourne, again showed his Odontoglossum × Adrianæ Rochfordianum, with two strong spikes (Cultural Commendation). G. W. Bird, Esq., Manor House, West Wickham (gr., Mr. Redden, showed Odontoglossum × Andersonianum Mrs. G. Bird, O. crispum Margaret Bird, and O. c. Catherine Bird, all good varieties and distinct. T. B. Haywood, Esq., Woodhatch, Reigate (gr., Mr. C. J. Salter), sent Odontoglossum crispum, Woodhatch variety, a form of O. c. guttatum.

Messrs. F. Sander & Co, St. Albans, showed a small group of Orchids, in which the most remarkable were a fine and large-flowered Lælio-Cattleya × Gottoiana, and the very handsome L.-C. × Ingrami superba (L. Dayana × C. aurea), the flower large, and the lip of an intensely deep claret-purple.

AWARDS.

Odontoglossum × *Adrianæ Ashworth'anum* from Elijah Ashworth, Esq, Harefield Hall, Wilmslow (gr., Mr. Holbrook). Flower large, and with broad segments, cream-white, densely spotted with light brown; lip white, crimped, fringed, and spotted (First-class Certificate).

Award of Merit.

Cattleya Mossiæ Victoria, from J. Gurney-Fowler, Esq., Glebelands, South Woodford (gr., Mr. J. Davis). Flowers very large and finely formed, white, with a delicate reticulation of light purple on the broad petals, the centre of the lip being bright yellow, with a few reddish markings.

Cattleya Eldorado, Glebelands var., from J. Gurney-Fowler, Esq. Flower bright rose coloured; front of the lip dark claret-crimson, tube orange; flower very fragrant.

Cattleya Mossiæ albescens, from Sir Frederick Wigan, Bart. gr., Mr. W. H. Young), resembling C. M. Wagneri, but with an almost imperceptible blush tint.

Odontoglossum × *Coradinei Crawshayanum*, from De B. Crawshay, Esq. (gr., Mr. S. Cooke). Flowers of the typical form, but larger; bright yellow, with large brown blotches.

Lælio-Cattleya × *Lucilia* (C. Dowiana ♂, L.-C. × Schilleriana ♀), from Messrs. Jas. Veitch & Sons. Flowers cream-white; the petals slightly tipped with purple. Lip yellow at the base, changing to cream-white towards the margin, the front portion veined purple.

Epidendrum × *Langleyense* (Pseud-epidendrum ♂, Wallisii ♀), from Messrs. Jas. Veitch & Sons. A singular cross with the scarlet-lipped E. pseud-epidendrum, which it resembles in form. Sepals and petals yellow; lip orange, closely streaked with purple around the callus.

Botanical Certificates.

Bartholina pectinata, from Leopold de Rothschild, Esq., Gunnersbury (gr., Mr. J. Hudson). A singular Cape terrestrial Orchid, with reniform, fleshy leaves, and curious pale blue, laciniated flowers.

Eria extinctoria, from Sir Fred. Wigan, Bart. (gr., Mr. H. Young). A pigmy among Orchids, its slender stems bearing whitish flowers, rising from very small clustered pseudo-bulbs.

Bulbophyllum nutans, from A. H. Smee, Esq., Carshalton (gr., Mr. W. E. Humphreys). A singular species, with nodding racemes of rather large, purplish flowers, with slender petals and a purple lip.

Bulbophyllum modestum, from A. H. Smee, Esq. A small species, with cream-white flowers.

Fruit and Vegetable Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. George Bunyard, E. Shaw Blaker, Jas. H. Veitch, A. H. Pearson, A. Dean, S. Mortimer, J. W. Bates, Geo. Wythes, H. Balderson, James Smith, and S. Norman.

Collection of Vegetables for the Sherwood Cup Competition.—Lord Aldenham, Aldenham House, Elstree (gr., Mr. E. Beckett), exhibited one of the best collections of vegetables ever observed at this part of the season; especially excellent being Cos and Cabbage Lettuces. Cabbages, Cauliflowers, Globe Artichokes, Victoria Rhubarb, very stout stalks; Potatos, viz., Snowdrop, Sharpe's Victor, Mona's Pride, and Windsor Castle; Holborn Model Leek, of enormous size, and excellently blanched; Early Gem and Long Forcing Carrots; Peas Thos. Laxton and Early Morn; Crimson Ball Egyptian Beet of this season's growth; excellent Vegetable-Marrows, Pen-y-Byd, and others; Tomatos, red and yellow varieties; Cucumbers, French Beans, new Turnips, and Broad and French Beans. No other entry was made in this competition.

Lord Foley, Ruxley Lodge, Esher (gr., Mr. Miller), was awarded a Bronze Banksian Medal for a collection of varieties of Melons.

A Silver Banksian Medal was awarded to Mr. S. Mortimer, Swiss Nursery, Rowledge, Farnham, for twelve Melons of the variety Hero of Lockinge, medium-sized, well-netted examples.

F. C. Stoop, Esq., Westall, Byfleet (gr., Mr. G. Carpenter), showed a quantity of Purslane, a herb used as salad, and once common in gardens, but now rarely grown in this country. Botanically, it is Portulacca sativa.

Messrs. Harrison & Sons, nursery and seedsmen, Leicester, showed a fine late Broccoli (six), with a whitish curd, and named "Leicester Late." It has a head well protected by the short leaves, and the merit of being undoubtedly late.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

June 8.—There were present on this occasion, Messrs. G. Shorland Ball, chairman; G. W. Law-Schofield, vice-chairman; R. Johnson, C. Parker (new member), J. Cypher J. Robson, W. Duckworth (new member), W. Thompson, Dr. Hodgkinson, and P. Weathers (hon. sec.).

This was the first meeting of the Society's third year of existence, and it may not be out of place here to remark that during the short time the Society has been working it has done an immense amount of work, and certainly created a greater interest amongst the Lancashire amateurs than hitherto prevailed.

A Gold Medal was offered last year for the member of the Society who gained the highest number of points during the year for merit; and at the last meeting it was found that John Leemann, Esq., of Heaton Mersey (gr., Mr. Edge), was the fortunate winner of this Award. Thos. Statter, Esq., of Whitefield (gr., Mr. Johnson), being only a few points short, and therefore a strong 2nd. There is no doubt that encouragement of this description tends to make an amateur take an interest and pride in his collection, and I have no doubt there will be a strong competition again in the season 1899—1900 for the coveted honours. The Society starts on the third year of its career with a balance in hand of over £50, and several valuable assets.

O. O. Wrigley, Esq., Bridge Hall, Bury (gr., Mr. Rogers), showed Cattleya Mendeli, Wrigley's var., a pleasing Cattleya of a soft tone of colour, with an exceedingly pale, almost white lip, and a throat of a citron-yellow tint (an Award of Merit). Cypripedium Gowerianum magnificum came from the same exhibitor, and was given a First-class Certificate.

Messrs. Charlesworth & Co., Bradford, had a superb form of Cattleya Reineckiana, which was awarded a First-class Certificate; a very pretty C. Mossiæ, named Princess, was passed; and Stanhopea tigrina, Charlesworth's var., a very gorgeous form of this fine old Orchid, was given an Award of Merit.

John Leemann, Esq., Heaton Mersey (gr., Mr. Edge), staged a handsome and valuable lot of plants, the most notable of which was Lælio-Cattleya × Canhamiana, var. "Duke of York," a lovely flower, of fine proportions and great brilliancy of tints, which was unanimously admired by the whole of the Committee, and which was awarded a First-class Certificate; and the Society giving instructions that a painting be made of the flower and it be put on record. L.-C. × Iolanthe var. grandiflora received an Award of Merit. A plant of L.-C. × Arnoldiana received an Award of Merit. A beautiful form of Odontoglossum Pescatorei called album received a First-class Certificate. A Silver-gilt Medal being awarded for the group.

Thos. Statter, Esq., Stand Hall, Whitefield, exhibited a fine form of Lælia purpurata, named Statteriana; but an objection was entered against this name, as it is said to be precisely the same as one shown in London under the name of L. p. Annie Louise. The plant was thereupon given a First-class Certificate under the latter name.

Richard Ashworth, Esq., Newchurch (gr., Mr. Pidsley), exhibited Lælio-Cattleya × Canhamiana, which obtained an Award of Merit, as did also Lælia majalis from the same exhibitor.

G. Shorland Ball, Esq., Wilmslow (gr., Mr. Gibbons), showed Cypripedium Lawrenceanum var. Hyeanum, which has already been certificated; a magnificent C. callosum var. Sanderæ, and whether there may or may not be varieties of this albino, that brought before the committee was superior to anything previously seen by them, and a First-class Certificate was unanimously awarded, the plant to be painted for record.

Mr. A. J. Keeling sent a few pretty varieties of Cattleya Mendeli and C. Mossiæ, and a supposed natural hybrid Cattleya between C. Mossiæ and C. speciosissima, the exhibitor obtaining a Vote of Thanks.

W. G. Groves, Esq., Windermere (gr., Mr. Robert Shaw), sent three meritorious plants in a fine Odontoglossum Wilckeanum (First-class Certificate); O. Alexandræ "Groves' var.," a flower of size and substance, but not quite round, and the petals heavily spotted, a distinct feature of the flower being the beautiful fringing of the segments (Award of Merit); Phalænopsis grandiflora from the same collection received an Award of Merit. W. Duckworth, Esq., Hexton (gr., Mr. Tindall), showed a fine white Cattleya Mossiæ. Mr. John Robson, Altrincham, staged a plant of Odontoglossum hystrix, very light in its colouring. Mr. J. Cypher, Nurseryman, Cheltenham, had a few good forms of Cattleya Mossiæ and Cattleya Mendeli. Messrs. Heath & Son staged various forms of Cattleyas. *P. W.*

THE YORKSHIRE GALA.

June 14, 15, 16.—The Horticultural Show was opened on Wednesday under most auspicious circumstances. The entries were as numerous as usual, and in almost all the classes there was keen competition. The general effect of the Exhibition was most satisfactory, and in the case of individual classes, each was of much interest. The groups arranged for effect were put up in capital style, and the quality of the plants was high. Orchids were numerous, and very choice. Stove and greenhouse plants were represented by large specimens full of flower.

Immediately upon entering the tent, one was struck with the excellence of the arrangements; a broad walk was banked on one side by a magnificent exhibit from Messrs. Fisher, Son, & Sibray, Handsworth. This group, beautifully undulated with an irregular edging, was composed at one end of a fine collection of Rhododendrons full of flower; the centre portion being of Acers in every form and variety, Bamboos, Spiræas, Euonymus, Standard Ivies, choice Coniferæ. Adjoining these was a grand collection of Crotons and Aralias, above which were suspended pitcher-plants in baskets; and again a large exhibit of Cattleyas, Cypripediums, and Odontoglossums.

On the opposite side of the entrance, Messrs. W. Cutbush & Sons, Highgate, had a large and varied exhibit of clipped Yews in fantastic shapes. Adjoining these, the same firm had a large display of Carnations with Bamboos and Rhododendrons; at their back, a fine mound of Richardia Elliotiana, edged with Saxifraga pyramidalis, and Ferns, imparting a neat finish.

There were large-sized Crotons and Palms. The fruit was generally good, and the Peaches and Nectarines of good colour. Strawberries were ripe and of large size. There were many fine collections of cut flowers of herbaceous plants.

Stove and Greenhouse Plants.

The end of this entrance was devoted to the stove and greenhouse plants with immense Palms overhead. Here Mr. J. Cypher, Cheltenham, showed in his usually successful manner, being 1st for twelve stove or greenhouse plants in bloom, and having Erica Cavendishi, Erica ventricosa, E. magnifica, large and full of flower; Clerodendron Balfourianum, Anthurium Scherzerianum, Bougainvillea Sanderiana, Ampelopsis macrantha rosea, Azalea Souvenir de Prince Albert, &c. The 2nd prize was awarded to Mr. W. Vause. Mr. Cypher was 1st also for six stove or greenhouse plants in which were large plants of Bougainvillea Sanderiana, Franciscea eximia, and Ericas, full of flower.

For three plants Mr. Cypher was also to the fore.

Orchids.

The Orchids were very numerous, and much competition was observable. For a table of Orchids, 10 feet by 4 feet, where cut flowers were also admitted, Mr. J. Cypher was placed 1st for a beautifully light arrangement, in which Bamboos, Dendrobiums, and Oncidiums were well intermixed at the back, and the centre and front was composed of Cattleyas Mossiæ and Mendeli, &c. Lælia purpurata, L. tenebrosa, Odontoglossum vexillarium, Epiphronitis Veitchi, and Cypripediums. Mr. J. Robson, Altrincham, was a good 2nd, having Oncidiums, Sobralias, Epidendrum prismatocarpum, Odontoglossum crispum in quantities, Anguloa Clowesii, Cypripedium bellatulum, and others, the whole edged with Ferns.

For ten Orchids Mr. Cypher was again 1st, with Odontoglossum vexillarium, with twelve spikes; Epidendrum vitellinum majus, with twenty-four spikes; Lælia tenebrosa, L. purpurata, Oncidium sarcodes, Cattleya Mossiæ, C. Warneri, &c. Mr. J. Robson was 2nd, and showed a very large specimen of Oncidium macranthum.

Mr. Cypher was again 1st for six Orchids, being followed by Mr. W. P. Burkenshaw.

For six Orchids, new or rare plants, not made up, Mr. T. Statter, Whitefield, Manchester, was 1st, with choice plants of Lælio-Cattleya × Phœbe, C. Mendeli albanensis, Cypripedium callosum Sanderæ, Lælia purpurata Statteriana, and others.

For three new or rare Orchids, Mr. Burkenshaw was 1st. For a single Orchid, Mrs. Tetley, Leeds, was 1st, with Aërides Fieldingi, carrying five spikes.

Messrs. B. S. Williams & Son, Holloway, had a fine display of Cattleyas, Lælias, Odontoglossums, &c; and Lælio-Cattleya Edouard André, Aërides expansum leonis, Cymbidium Lowi, Oncidium macranthum and Lælia purpurata, Williamsii, and a large mass of Utricularia montana were very prominent.

Messrs. Charlesworth & Co., Bradford, had a nice collection of plants, in which Thunia Marshalliana, Oncidium macranthum, Cymbidium Lowi, Lælia tenebrosa, in fine colour and form, Oncidium hastatum, Odontoglossum Vuylstekeanum, C. Reineckiana, L.-C. radiata and Thunia Veitchi were well represented.

Messrs. J. Cowan & Co., Liverpool, had a capital exhibit, in which Venda Parishi was noticed, among choice Cattleyas, Lælias, and Odontoglossums.

Messrs. J. Veitch & Sons, Chelsea, had a small but choice collection of hybrids—Lælio-Cattleya Eudora and L.-C. Eudora alba, L.-C. Canhamiana, L.-C. Wellsiana albida, C. Mossiæ excellens, C. Schrœderiana, and L.-C. Zephrya. Spathoglottis aureo-Viellardi was also in this collection.

Florists' Flowers.

A large tent devoted to Fuchsias and Pelargoniums, was full of colour, many of the plants being of excellent quality, large in size, and wonderfully well bloomed.

For twelve Show Pelargoniums, Mr. T. J. Hingston was well 1st with magnificent plants, just 4 feet in diameter, almost flat, and densely covered with flowers.

For six Show Pelargoniums, Mr. Tetley was 1st with Kingston Beauty, Magpie, Painted Lady, Madame Richard, and Madame de Desmoulin, as his best varieties; Mr. Hingston was 1st for three plants.

For a group of not fewer than eight fancy Pelargoniums, Mrs. Tetley was 1st, with splendid plants; the same exhibitor being also 1st for twelve, six, and three zonal Nosegay Pelargoniums, and for nine plants of double-flowered Pelargoniums.

The Ivy-leaf section of Pelargoniums was not good.

A magnificent display of Calceolarias was staged by Messrs. Clibran, Manchester, some 200 dwarf, compact plants being full of flowers of distinct colours, self and spotted, no two alike among them.

Mr. J. Forbes, Hawick, staged an exhibit of herbaceous Phlox and Pentstemons, very distinct in marking and large in flower. A. Wilson, Esq., Kelso, had a fine group of Carnations, which was awarded a 1st prize; Messrs. Laing & Mather being 2nd.

Ferns.

Ferns were well shown, some fine Davallias being observed in several collections. For six exotic Ferns Mrs. Gurney Pease was 1st, with Davallia fijiensis, D. Mooreana, Microlepia hirta cristata, Gleichenia Mendeli, Adiantum Farleyense and another. Messrs. R. Sampson & Son were 2nd. For three exotic Ferns the Rt. Hon. Lord Barnard was in the fore with Davallia polyantha, an immense plant; D. Mooreana, and a golden Gymnogramma; Mrs. Gurney Pease was 2nd, with Davallia fijiensis, D. F. plumosa, and Adiantum concinnum.

For one specimen of exotic Fern the Rev. G. Yates was 1st, with a large plant of Adiantum Farleyense. Messrs. J. Hill & Son, Edmonton, were 2nd, with Nephrolepis rufescens species. The latter firm had a large collection of choice Ferns, in splendid condition. Here were A. capillus-veneris, A. Farleyense, macrophyllum, rhodophyllum, aglaomorpha Meyeriana &c. There were classes also for hardy species of Ferns.

Groups for Effect.

For a group of miscellaneous plants, in or out of bloom, to occupy a space not exceeding 300 square feet, Mr. C. J. Mee was 1st, with a fine collection of Palms, Alocasias, Crotons, and Ferns, beautifully arranged. Mrs. Gurney Pease was 2nd, with a very pretty arrangement. These groups and others were most effectively arranged.

Capital Crotons were shown by Messrs. Simpson, Mrs. Gurney Pease, and E. H. Faber, Esq., who took prizes in the order named.

Roses.

These were shown in considerable numbers, but the heat soon caused many of the flowers to lose their freshness. For seventy-two single blooms in not fewer than thirty-six varieties, Mr. W. Hutchinson was 1st, with choice and large blooms. Messrs. J. & A. May, 2nd, and Mr. Mount, of Canterbury, 3rd. The last-named exhibitor was 1st for forty-eight blooms, and Messrs. A. & J. May, 2nd.

For eighteen distinct varieties, Messrs. Harkness & Sons were first, and Mr. Mount, 2nd.

Fruit and Vegetables.

Fruit was exhibited in moderate quantity. For a decorative table, to measure 10 feet by 4 feet 6 inches, and to include not more than fourteen dishes, the 1st prize was won by Sir J. W. Pease. A small plant of Cocos was in the centre with two vases charmingly furnished with Oncidium flexuosum, Odontoglossum crispum, Brassia verrucosa, Grasses and Ferns. The fruit consisted of Black and White Grapes, Melons, Peaches, Nectarines, Cherries, Figs, &c., in all, fourteen dishes. The Earl of Harrington (gr., Mr. Goodacre), was 2nd. The centre of this table being decorated chiefly with Odontoglossum crispum.

For a collection of six kinds of fruit, the Right Hon. Lord Barnard was 1st with Black Hamburgh and Foster's Seedling Grapes, good Peaches, Nectarines, Figs and Melons; Sir J. W. Pease was 2nd. Mr. W. Sheepshanks was 1st for four kinds, showing good Black Hamburgh Grapes, Melons, Rivers' Orange Nectarines, and Peaches. The Earl of Londesborough and Mr. F. B. Groshian, were respectively 1st and 2nd for three bunches of Black Grapes; whilst the latter exhibitor was 1st with three bunches of a white variety, showing Buckland Sweetwater. Mr. J. Edmonds, Bestwood Gardens, was 1st for a dish of Peaches, showing good Royal George; and Mr. Goodacre, gr. to the Earl of Harrington, 2nd. Nectarines were good, Mr. J. Edmonds being the best exhibitor. Viscount Raincliffe was 1st for a scarlet flesh Melon, and Sir J. W. Pease 1st with a green flesh fruit. The Right Hon. Lord Barnard was 1st with six Figs. Sir J. W. Pease 1st for Cherries; and the Earl of Harrington 1st for Strawberries. Lady Beaumont was successful with twelve Tomatos, showing Frogmore Scarlet.

Sir J. W. Pease was 1st with a very nice collection of Vegetables. A capital lot of fruiting plants of Strawberry, Laxton's Leader, was shown by Messrs. Laxton, Bedford.

Miscellaneous.

Messrs. Cutbush, of London, had a magnificent display of hardy cut flowers. For twelve bunches of hardy border flowers, Messrs. J. Burrel & Co., were well 1st, and made a fine display. Gloxinias were shown in splendid form by Mr. J. J. Upton, the blooms being of immense size, and distinct in colour.

Messrs. Harkness were 1st with a grand stand of hardy herbaceous flowers, covering a space 18 feet by 4 feet; Messrs. Smith & Co., Worcester, were 2nd.

A splendid lot of Calceolarias, mixed with Coleus, Maples, Dracænas, and mosses, was shown by Messrs. Hingston, and were awarded 1st prize.

Begonias call for no special remark.

Messrs. Kelway & Sons, Langport, Somerset, had a grand display of Pæonies, Amaryllis, and choice herbaceous plants.

AWARDS.

Gold Medal.

For a miscellaneous group of plants, to Messsrs. Fisher, Son & Sibray.

For a miscellaneous group of plants, to Messrs. Cutbush & Sons.

For Orchids, to Messrs. Charlesworth & Co.

Silver Medal.

For miscellaneous plants, to Messrs. R. Smith & Co.

For a group of Calceolarias, to Messrs Clibran & Son.

For a group of Orchids, to Messrs. B. S. Williams & Son.

For a group of Orchids, to Messrs. Cowan & Co.

For a collection of Clematis, to Messrs. Jackman & Son.

For a collection of Ferns, to Messrs. J. Hill & Son.

WARGRAVE & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

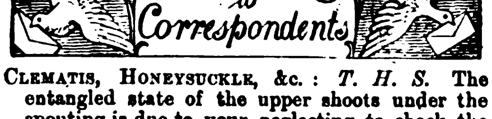
June 7.—The first monthly meeting of the Society was held at Wargrave on the above date, Mr. W. Pope presiding.

Mr. W. Bazeley, of The Nurseries, Twyford, read a useful paper on "Zonal Pelargoniums," tracing the gradual development of this favourite and useful flower. The cultivation, method of striking cuttings, kinds of soils and manures best suited to them, were in turn dwelt upon. Cut-blooms of various kinds were shown, including a new one raised by himself. A discussion took place, in which many joined. A vote of thanks was passed to Mr. Bazeley for his paper.

A Madagascar Rubber-Tree.—M. Henri Jumelle contributes to the *Comptes Rendus* for May 29, a paper on the Guidroa, a rubber-tree of Madagascar. The writer mentions that the plant has hitherto been known only under its native name, but that now, thanks to specimens sent from Suberbieville (!) by M. Périer de la Bathié, it has been possible to ascertain whether it is a new species, or can be identified with any that is already known. The conclusion arrived at is, that the Guidroa, though clearly belonging to the Mascarenhasia genus, does not exactly resemble either of the fifteen or sixteen known species, but may be held to be a new species, and may be named Mascarenhasia velutina, in allusion to the very characteristic velvety substance of the leaves. M. Jumelle describes the manner in which the rubber is gathered from the trees by the Sakalaves. During the dry season, when the milky juice is very thick, they make, he says, numerous incisions in the trunks. The milky juice coagulates almost immediately below the wound, forming small bands of gum which the workers remove after an hour, and which they agglomerate into balls. In this way one man can easily gather a kilogram of the gum in one day. The caoutchouc thus obtained is of good quality, and even, it appears, superior to that gained by ebullition. Thus it seems likely that the Mascarenhasia genus, only found on the east side of Africa and in Madagascar (especially in the north and east), will play a more important part in furnishing caoutchouc plants than has previously been thought likely.

TRADE NOTICE.

Mr. E. J. Deal having been appointed general manager of the firm of Messrs. W. W. Johnson & Son, Ltd., Boston, Lincs., has resigned his position with Messrs. Sutton & Sons, Reading.



Clematis, Honeysuckle, &c.: *T. H. S.* The entangled state of the upper shoots under the spouting is due to your neglecting to check the rampant growths at the top by a timely nipping-out of their points and letting the lower shoots alone, meantime fastening the former in a horizontal or even downward direction with nails and shreds, bast, &c. The nipping-out of the points may need to be performed twice if growth is very vigorous in the upper part. This sort of treatment is applicable to almost every kind of plant used on walls and fences.

Chrysanthemums: *J. B.* There is nothing in the specimen sent that indicates the cause of the injury. The cause was evidently a violent one, and something other than disease.

Mushrooms: *E. B. D., Addiscombe.* The fungi are Agaricus Elvensis, B., a species first described by M. J. Berkeley, and found several times since in England and in France. It is an excellent edible Mushroom, and is figured in *Cooke's Illustrations*, pl. 522. *M. C. C.*

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—Correspondent.* 1, Phlox setacea var.; 2, P. subulata frondosa; 3, P. s. var.; 4, P. s. Nelsoni; 5, P. reptans (syn. verna, stolonifera, and others).—*M. R., No.* 2. Nothoscordum fragrans.—*John Newton.* Lonicera involucrata, syn. L. Ledebouri.—*Pinner.* 1, not found; 2, Hyacinthus comosus; 3, Veronica Teucrium.—*Scot.* 1, Lonicera tatarica; 2, Ornithogalum nutans.—*C. F.* 1, Dielytra spectabilis; 2, Geranium sanguineum; 3, Hyacinthus comosus; 4, Veronica gentianoides.—*R. C. B.* A lilac variety of Scilla campanulata.—*Cardboard Box — no name.* Specimens withered and blackened beyond recognition; as a guess we note, 1, probably a Vaccinium; 2, flowers of an Ash (Fraxinus sp.); 3, Spiræa, perhaps hypericifolia.—*Twenty Years' Reader.* 1, Dendrobium Pierardi; 2, Dendrobium devonianum.—*W. W. B., Sheffield.* 1, Cattleya Mendeli; 2, Sobralia macrantha; 3, Cirrhopetalum Colletti.—*P. H., Cambs.* Vanda cœrulescens.—*J. A. B.* 1, Polygonum Bistorta; 2, Equisetum arvense; 3, Muscari comosum; 4, Chelidonium majus.—*J. H. B.* Potentilla Tormentilla.—*W. W.* Ornus europæa, the flowering Ash.—*C. G.* 1, Ulmus montana, Witch-Elm; 2, Nasturtium amphibium; 3, Barbarea vulgaris; 4, Lepidium Draba; 5, Sedum carneum variegatum; 6, Senebiera coronopus.—*J. P. L.* 1, Quercus coccinea; 2, Leucothoe axillaris; 3, Ledum latifolium; 4, Cratægus—perhaps C. crus-galli; 5, Leiophyllum thymifolium, *alias* Ledum buxifolium.—*T. E. S.* Trollius europæus; seed or division of the roots in early autumn or spring.—*No name, card-board-box.* 1, Trollius europæus; 2, Ranunculus aconitifolius; 3, Hesperis matronalis; 4, Ornithogalum umbellatum; 5, Spiræa callosa; 6, Ajuga reptans.—*W. B.* Bromus sterilis.—*Pope & Sons.* Piptanthus natalensis, Natal Laburnum.

Notice to quit Service: *G. D.* In the absence of any written agreement to the contrary, a month's notice on either side is required. Of course, if you must quit at once from no fault on your side, you can claim house-rent, allowance for coal, and other perquisites for a month.

Strawberry Plants not Flowering: *Anxious.* The soil in which the plants grow has been so much enriched with manure that leaf-growth alone has been made. Sometimes the Strawberry reverts to its original, i.e., a diœcious state, and male and female blooms are then borne on different plants. The Hautbois is persistently diœcious, and unless a pretty good proportion of male and female plants grow together in a bed, the produce is poor. We should advise you to obtain a fresh stock of young plants from beds in bearing this year; but not to destroy the barren ones, as these may carry fruit another year, and we think that this is the more probable, seeing that no flowers at all have appeared this year.

Tomatos: *D. G.* The roots show no injury. The leaves are probably affected with the sleepy disease often described in our columns.

Tulip: *Chas. S. G.*—The Tulip sent is probably an escape from cultivation, and it has reverted to a great extent towards an original species, probably F. Gesneriana.

THE
Gardeners' Chronicle
No. 652.—*SATURDAY, JUNE* 24, 1899.

CHLOROSIS IN FRUIT TREES.

ONE of the most eminent of the many able writers who have enriched the pages of the *Gardeners' Chronicle*, the Rev. J. M. Berkeley, correctly referred to chlorosis as an extremely formidable plant-disease, and defined it as consisting in "a pallid condition of the plant, in which the tissues are weak, and unable to contend against severe changes; the cells being more or less destitute of chlorophyll." Horticulturists have occasionally become unpleasantly familiar with the disastrous effects of the disease, particularly in the cultivation of Cucumbers and Melons, and in too many cases the usual remedies proposed have proved of no avail. Long before the nature of the disease was known to me, I had witnessed the mischief it could occasion, and had assisted in the application of many substances that were supposed to be beneficial, but which rarely realised the expectations formed concerning them. Good effects would sometimes result from the employment of iron sulphate solutions, but this also would often fail, probably because the plants dealt with were annuals, and the disease was too far advanced before the applications were commenced.

Scientific investigators have agreed that chlorosis is mainly due to a deficiency of iron in the soil, for though the quantity required to render a plant healthy is extremely small, yet in its absence, microscopic examination has shown that the protoplasm in the cells of the leaf is without colour, and the chlorophyll granules are not formed. In the majority of published analyses of plants, iron is commonly omitted, as it is usually less than 1 per cent. of the ash, yet in some instances as much as 6 per cent. has been recorded, but this is exceptional, and amongst hardy fruits the only case known to me of a similar high percentage is the fruit of the Greengage. With regard to soil analyses also, it is seldom that the proportion of iron is given separately, and in a series of analyses recently prepared by Dr. Bernard Dyer for the Cornwall County Council, oxide of iron and alumina are given together as varying from about 5 to 14 per cent. On the plots where there is the lowest proportion of iron and alumina, there is also a corresponding low percentage of potash, and the relatively small crops produced are probably due to this deficiency; at least, in the report issued I can find no reference to the foliage of the plants showing indication of chlorosis.

Experiments undertaken by Sachs and other continental observers, demonstrated that when seedlings were grown in substances free from iron, the leaves gradually became white, and that when iron sulphate was subsequently applied the effect was seen within twenty-four hours, chlorophyll granules being formed immediately, and in a few days the plants were quite green. The process of assimilation is dependent upon the production of chlorophyll, and consequently in its absence or deficiency growth is arrested, or can only proceed at the expense of previously-stored materials. Those who are interested in this part of the subject would find a most valuable record of experiments in the "Chemistry and Physiology of Foliage Leaves," by Mr. Horace T. Brown, F.R.S., and Mr. G. H. Morris, Ph.D., in the *Journal of the Chemical Society*, May, 1893.

Comparatively seldom are hardy fruit trees seriously subject to chlorosis, but some time ago my attention was called to a remarkable case in Hertfordshire, at Hamels Park, near Buntingford, the residence of H. Shepherd-Cross, Esq., M.P., where several series of valuable and highly interesting experiments have been carried out during the past fourteen years. I have had the opportunity of carefully examining the trees in the gardens, and have further been favoured with full details of the experiments, and accorded permission to make use of them, with the result that the following digest has been prepared. Mr. Shepherd-Cross has spared no expense or trouble in the investigations, and his efforts have been ably supported by his gardener, Mr. Wallis, from whom I have received much kind attention in my enquiries.

The soil at Hamels Park is a heavy marl,[*] the proportion of chalk being large, and the same character prevails over a wide district, especially on the higher ground. The land is fertile, and suits many crops remarkably well, all leguminous plants, for instance, both in gardens and farms, such as Peas, Beans, and Clover, flourish amazingly; so also do the Cabbage and Turnip family, "club" being unknown. Indeed, it is stated that Savoy Cabbages were grown on the same plot of ground for ten years in succession without deterioration, and without any trouble resulting from either "club" or wireworm. Mr. Shepherd-Cross requested Dr. J. A. Voelcker to take samples of the soil for analysis in 1885, with the following result:—

Dr. Voelcker's Analysis of the Hamels Park Soil.

	Per cent.
Organic matter [†] and loss on heating ...	5·64
Oxide of iron	4·39
Alumina	6·36
Carbonate of lime	18·53
Sulphate of lime	0·22
Magnesia	0·47
Soda	0·25
Potash	0·48
Phosphoric acid	0·14
Insoluble silicates and sand	68·57
	100·00

Some years later, namely, in 1894, it was decided to have a special analysis of the chalk alone; this task was also entrusted to Dr. Voelcker, and his record is here appended:—

Analysis of Chalk.

Moisture	0·10
Oxide of iron and alumina	0·10
Carbonate of lime	99·20
Magnesia, alkalies, &c.	0·30
Silica	0·30
	100·00

Judging from the above, the opinion would be formed that while not rich in potash, the soil contains as much as many others, its chief marked characters being a low percentage of phosphoric acid, a small proportion of organic matter, and, consequently, of nitrogen, with a large quantity of carbonate of lime. The iron, too, is quite equal to that in many soils where no trouble is caused by chlorosis.

The behaviour of fruit-trees at Hamels Park is, however, so remarkable, and failure so persistently followed every early attempt at their culture, that for some years it seemed a hopeless task. All kinds of hardy fruits failed in a similar manner. In two or three years from planting, the foliage on some branches would become pale or whitish; in the following year the leaves on these branches would be still weaker, they were readily scorched in the sun, and later in the season they would become perforated, "appearing," as Mr. Wallis says, "as if they had been shot." The branches gradually lost strength, and were unable to produce any foliage, while in the Cherry and Apricot the affected portions quickly died.

In most cases where chlorosis became manifest, fruit-buds were not produced, but when any fruits were borne on Apples or Pears so affected they failed to develop satisfactorily, and were disfigured by "scab." Plum trees were found to resist the disease for the longest time before entirely succumbing, but such fruits as might be produced proved almost worthless. Peaches and Nectarines showed similar effects to Plums, Apricots, and Cherries, while, amongst other fruits that suffer, must be named the Gooseberry and Currant, Raspberries, and even Strawberries, the last seldom surviving beyond the second year, but dying soon after the flowers have opened. It may be added that Roses and Laurels are subject to the disease; Bouvardias and Chrysanthemums, with many other ornamental plants, also fall victims when grown in the same soil, either out-of-doors or under glass. The evil, it will be seen from the foregoing, is very general, and afforded ample scope for a thorough investigation respecting the causes and possible remedies. It was suggested that the employment of different stocks for the fruit trees might act beneficially, but experience proved that this had not the effect supposed, and those now in use, and satisfactory, are the broad-leaved English Paradise for Apples, the Quince for Pears, and the seedling Greengage for Plums.

It has been considered that cold soils and bad drainage may either operate as direct causes, or at least increase the injuries arising from chlorosis. For this reason experiments were commenced, with the object of improving the conditions, so that deep rooting might be prevented, and thorough drainage be ensured. To this end, stations were prepared for fruit-trees by removing the soil to the depth of 4 feet; the base of each was cemented and connected by drains 6 inches lower. Upon the cement a layer of brick-rubble was placed 1 foot deep; and above this, 3 feet of soil, in which the trees were planted; or in a few cases the soil was raised a foot above the ordinary surface. In all these experiments the foliage failed at the usual time, and in the same way, as with those trees receiving no special treatment.

Stations were next prepared in a similar manner, but all the old soil was removed, fresh turfy-loam being substituted. The trees made better progress in this at first, and the foliage continued healthy for a longer period, but it ultimately failed, and the progress of the disease was then more rapid, especially as regards Peaches. Many of the ordinary natural manures were employed at different times, including that from horses, cows, fatting bullocks, and pigs, either separately or in mixtures. The only appreciable results being that while the trees made a more vigorous growth for a time, they failed proportionately more rapidly afterwards. *R. Lewis Castle.*

(To be continued).

ORCHID NOTES AND GLEANINGS.

CATTLEYA LAWRENCEANA.

MR. HART of the Trinidad Botanic Garden has kindly sent us two flowers of this species, in both of which one of the lateral petals is adherent to the column, which is more curved than usual.

SELENIPEDIUM SCHRŒDERI ×.

Count Kerchove obligingly sends a flower of this form in which the two lower sepals are conjoined into one, and twisted so as to occupy the front of the flower, whilst the single lateral petal is placed opposite, or at the back; opposite this petal is the lip in the fore part of the flower. At the back of the flower is the column with a single anther Al and a two-lobed staminode. The ovary is two-lobed, with two placentas. There is thus a tendency for the parts of the flower to be arranged in twos, and in one straight vertical line one over another.

---

[*] The marl is 10 to 20 feet deep, resting on chalk.

[†] Containing nitrogen 0·28, equal to ammonia 0·34.

ABNORMAL CATTLEYA.

From the garden of Sir F. Wigan comes a curious flower of Cattleya Mossiæ. The parts of the flower are in twos instead of in threes, and there are two lips, so that the flower is regular. There are two sepals, one to the right, the other to the left, and one a little like the lip. Crossing these at right angles, are two lip-like petals, and in the centre an erect column with the anther on the top, as is the rule in such cases. The malformation thus depends on reduction of parts and peloria.

PROLIFEROUS BUDS OF PINUS SYLVESTRIS.

RECENTLY, passing through a plantation, we were struck by a peculiarly bushy appearance of the branches of a young tree of this species (fig. 147). On examination we found that the shoots of the year, instead of extending in length, were contracted or arrested in growth, and the pairs of leaves with their encircling bud-scales were huddled together into subglobose masses, each the size of a large Pea. From these projected the tips of the primary leaf-scales, so that a hedgehog-like appearance was presented. But this was not all. Between the two foliage-leaves was a terminal bud, consisting of an indefinite number of overlapping scales. At the base of each of these masses of scales were the dried remnants of a similar growth in the preceding year. It is possible these appearances are due to the irritation caused by insect-puncture, but we were not able to discover any insect or fungus.

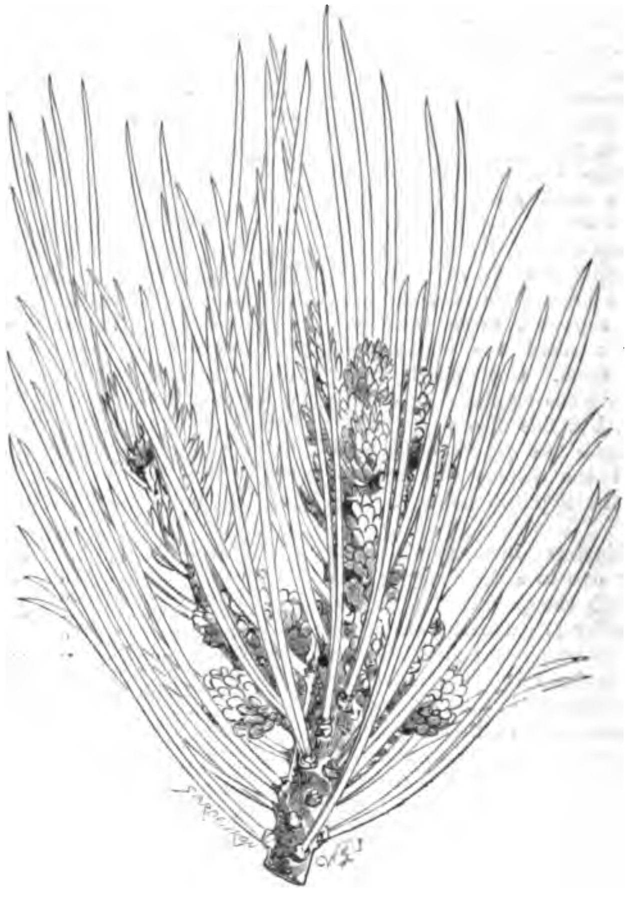

FIG. 147.—PROLIFEROUS BUDS OF PINUS SYLVESTRIS.

FORESTRY.

THE LEAFING OF TREES.

(Continued from p. 358.)

THE observations in question were made at over 200 stations scattered over the German Empire, and the results obtained were summarised in a report drawn up by Dr. Karl Wimmenauer, of Giessen. They covered a period of ten years, from 1885 to 1894, and extended to the leafing, fruiting, and autumn leaf-colouring of all the more important forest trees and shrubs. The more important of these conclusions arrived at, or which confirmed those of previous observers, had reference to the order in which different trees break into leaf, the time of flowering, ripening of the fruit, and yielding of seed; and the influence of latitude, longitude, and elevation in the several phases of growth.

The order of leafing was found to be as follows:—Larch, then Birch, Hornbeam, Beech, pedunculate and sessile-flowered Oaks, Silver Fir, Spruce and Scots Fir in the order named. At great altitudes the Hornbeam was frequently found to be later than the Beech, while the sessile-flowered Oak was usually later than the pedunculate species.

The time of flowering and fruiting is of no special interest, but the influence of situation exhibits some interesting features. Latitude had naturally more influence than longitude, and as the field of observation extended over 4½° of latitude, uninterrupted by sea or ocean currents, or other disturbing factors, the results obtained may be considered fairly trustworthy. Every degree of latitude was found to cause a difference of two to seven days in the leafing process, the comparisons being made between stations of the same altitude. Longitude was found to exert a slight but decided influence upon vegetation. From west to east every degree of longitude made a difference of half a day later in growth, probably owing to the influence of the Gulf Stream in the west, and the prevalence of cold-air currents in the east.

Altitude had, of course, the greatest effect in retarding or hastening growth, the stations being grouped at every 100 mètres. Up to an elevation of 300 mètres, no great difference was found to exist, the lowest situations being frequently, however, behind those at a higher elevation. This was, probably, owing to the late frosts, which occur in low-lying situations. Above 300 mètres, every 100 mètres in altitude retarded vegetation by from 2 to 2·5 days.

Another point of interest was the duration of growth, reckoning from the leafing in spring until the colouring of the leaves in autumn; and its influence upon the production of wood. In the observation field, the duration of vegetation was found to vary to the extent of a month or so, and this difference was responsible for a corresponding difference in the yield of Beech of about 2½ cubic mètres per hectare a year. With the Scots Fir rather a greater difference was observed in West Germany, and rather less in East Germany. The variations noted in individual years in the leafing and duration of growth extended over a period of thirty to thirty-five days in the former, and thirty to forty-five days in the latter phase of growth. The valleys of the chief rivers were noted separately, the greatest difference being noted in the case of the Elbe, the earliest leafing taking place on April 9, and the latest on May 15, while duration of growth varied from 140 to 185 days in the ten years.

It will be noticed that the difference in time between early and late individuals, localities, and years, is very much the same as regards the period of leafing, viz., thirty to forty days, and this coincidence opens up a field of speculation as to how far the influence of climate and situation may be counteracted by a careful selection of seeds and plants. If an interval of a month or six weeks occur between the leafing of two individuals growing side by side, or a certain number of individuals commence growth a fortnight or three weeks before the average, it is not unreasonable to assume that by growing such early individuals, we gain much the same advantage as would accrue from a warmer climate, or a lengthening of the period of growth. In horticulture the supply of fruit, flowers, and vegetables, is considerably extended by such selection of varieties, and if the question is of less economic importance in the case of forest trees, it certainly deserves consideration from a landscape point of view. By the use of hardy individuals in a backward climate, or a proper admixture of both early and late trees and shrubs, the beauties of both spring and autumn may be greatly intensified. With our fickle spring climate, precocity is often considered a disadvantage, and in some cases it may be so; but when we reflect that injurious late frosts and cold, cutting winds occur as frequently in late as in early spring, it seems that no method will effectually preclude all liability to climatic injuries. Probably little can be done to enliven the dull, monotonous green of a thickly-wooded landscape in July and August, but by retarding the spring and hastening the autumn foliage shades and tints, the dull period might be shortened by several weeks, and in effecting this, individuals may play as important a part as species or varieties. *A. C. Forbes.*

SCOTLAND.

ROSES.

THE alternating cold, wet, and intense heat which have been thus far the prominent meteorological features of the present year, have dealt the whole not unkindly with the queen of flowers. H.P.'s and Teas while I write are in the pink of condition; foliage broad, bright green, and almost without a flaw, though a slight incursion of aphis has just been met and annihilated; and the buds are equally promising, and withal early. During the whole of June we have been able to cut lovely buds of W. A. Richardson from the open, as well as Gloire de Dijon and a few others, the trees of which were pruned early in January. I am aware it closely approaches a floricultural delinquency to prune Roses early, and if it had not been that a fairly lengthy course of practical dissent, in its results not wholly unsuccessful, had rendered the writer somewhat callous, the weather in March must have been a cause of much grief, inasmuch as all the Roses had already been pruned.

One might attempt to grapple with the physiological bearing of the question, as for example, why a bare stump in the end of March should be less able to resist cold than an unpruned bush; or it might be treated of as a matter of locality, and the success of early pruning attributed almost entirely to that—but in any case, considering the great pleasure attending the enlargement and extension of the season of Roses, would it not be worth while to be cautious just a little less, and bold a wee bit more, as regards the time of pruning? That, however, by the way; for the Roses I wish more particularly to write of do not belong to the aristocracy of the family.

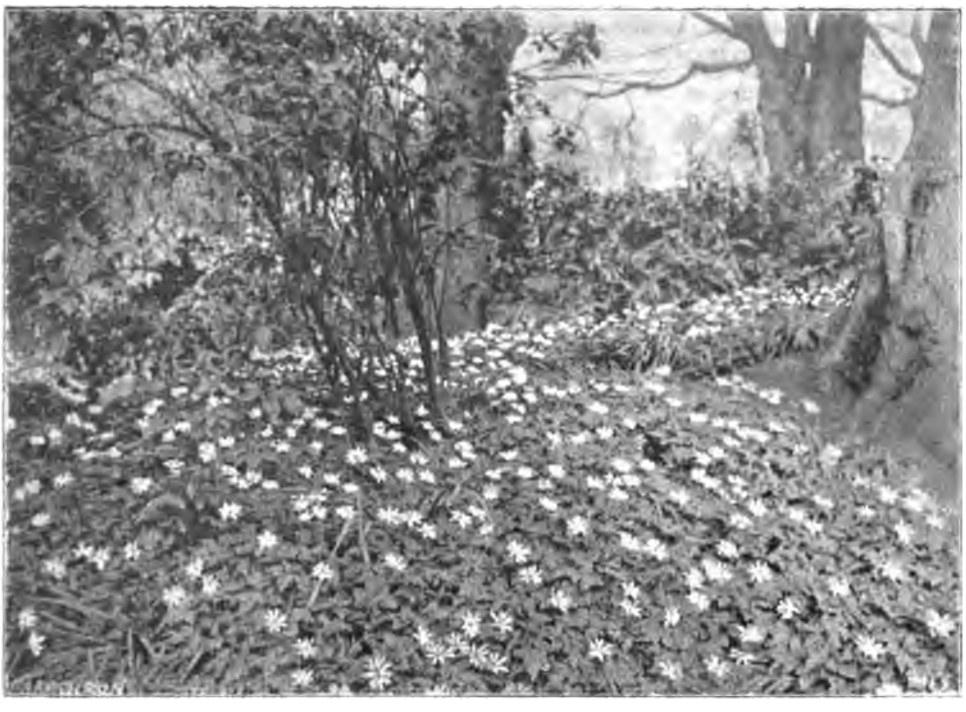

FIG. 148.—ANEMONE APENNINA, IN THE GARDEN OF PHILIP CROWLEY, ESQ., WADDON HOUSE, CROYDON.

I have been gathering from many quarters all kinds of nice Roses, and among these are some early ones that have been a very great delight. The most perfect of all, whether in free-blooming qualities combined with earliness, graceful habit, and delicious scent of sweet Eglantine, is one recommended to me by the late Mr. M. Dunn under the name of Rosa elegantissima, which, though cream-coloured, I have wondered if it might not be the yellow Sweet Briar of seventy or eighty years ago. Mr. Dunn employed the long shoots for mixing among flowers, and on this account it is very useful. But as a flowering plant it is even more so; while the flexile shoots, clothed with buds and expanded blooms, arranged in vases with flowering shoots of the Early Cream Honeysuckle, produce a soft, sweet, and harmonious effect of a pleasing nature. Another very early single Rose was sent me by Mr. Black from Carton; the colour is rosy-purple, and though the bloom is perplexingly fugacious, it is, nevertheless, so pretty and so early, that once grown one would not care ever to be without it again.

Yet another single Rose which, as a large plant, bloomed most profusely throughout the month is Paul's Carmine Pillar. It is, of course, a popular variety, and I only add that it must be left unpruned in order to be completely satisfactory. Double Scotch Roses began early in the month to exhibit the charms of their expanding blossoms. Only in one respect are they disappointing, and that is because of the very limited number of varieties it is possible to obtain. They have been procured from several sources including Dalkeith, but in every case they have largely turned out to be merely duplications of a few varieties reaching in number not far into the teens. Of their undoubted beauty, however, there can be no question, and though the petals when full expansion has been reached, drop very soon, yet they furnish so many buds in varying stages of growth that a display is provided during several weeks. The very distinct and sweet Stanwell Perpetual begins flowering at the same time with the above. *R. P. Brotherston.*

ANEMONE APENNINA.

We are indebted to Mr. Crowley for the photograph, showing a beautiful carpet of the blue Anemone apennina under the shade of trees in the wild garden. Nothing can be more pleasing than the growth of such plants in appropriate situations, as shown in our illustration (fig. 148); but when these plants are allowed to intrude into the lawns or dressed gardens, they become inappropriate, and much of their beauty is lost.

SOUTH AFRICAN NOTES.

THE FLORA OF JOHANNESBURG.

In Mr. Harry Bolus' excellent sketch of the flora of South Africa nearly the whole of the Transvaal is comprised in the great (floral) Kalahari region, which extends across South Africa from the mouth of the Orange River on the west to within nearly 300 miles of Delagoa Bay on the east. Roughly speaking, it is bounded on the north by the Tropic of Capricorn, and on the south by the Orange River. It is a grassy country, elevated above the sea from 1000 to 6000 feet, with isolated trees and shrubs. The rainfall varies from about 5 inches on the west side to 28 inches on the east. Rivers and springs are not very plentiful, but immense stores of underground water are known to exist at no great depth over a large part of the region. The summer heat is very great, and the winter on the higher ground is very cold.

The flora in the immediate neighbourhood of Johannesburg is not very rich, but some interesting plants have been met with—altitude 5000 to 6000 feet. The only tree we have (which was once abundant, but has been cut for firewood) is an Acacia, probably A. horrida; and the next in point of size and number is a Protea, which may be P. abyssinica, with large, handsome, pale red flowers, 3 to 4 inches across. The largest specimen of this seen was about 20 feet high, with a trunk 2 feet in diameter. Two remarkable sub-tropical shrubs are—a species of Star-Apple, Chrysophyllum magalis montanum (common name, "Stem-fruit"), an evergreen, large-leaved, Rhododendron-like shrub, growing 10 feet high, and furnished with very small, greenish, sessile flowers, and edible, red, oval fruits, 1 inch long; the other is a rambling, evergreen, Jasmine-like plant, Landolphia capensis, with terminal clusters of white, sweet-scented flowers, and fruits like a yellow Peach (common name, "Wild Peach"), 2 inches through, flavour pleasant, and much sought after by the "boys." Both these plants only grow on hill-sides facing north (the warm side), where frost is hardly ever known.

In similar places we find Clematis Stanleyi, certainly one of our finest flowering plants. It is of erect, shrubby habit, growing 4 to 6 feet high, and dies down to the ground every winter; the flowers are many, pale blue or purple, about 2½ inches across, followed by very ornamental, silver-white, fluffy seeds. It is difficult to transplant or grow in a garden; I have tried seeds, cuttings, and dug up roots with no success. Clematis brachiata is a rather common plant with small white flowers; another climbing species has much larger flowers, but I have never seen an entire plant. Between rocks a showy orange-yellow Gladiolus grows; also Dicoma Zeyheri, with hard, spiny, shining white bracts. Near by, a singular shrub with very woolly white leaves is not uncommon; it is Brachylæna sp., a Composite that spreads over rocks and is of scandent habit. Ficus, whose young leaves in spring are of a bright rose colour. In rocky clefts we find a tuberous-rooted rambling Cucumis, with showy red fruits; a white Hæmanthus, H. Bauri; also two rather handsome yellow-flowered Composites, Stobea radula and Berkheya acicularis. Amongst rocks is an orange-flowered succulent, Cotyledon orbicularis, and the handsome, very dwarf, scarlet-flowered Aloe Cooperi. Mesembryanthemums might be expected to be common, but I have only met with one dwarf, red-flowered species, although a friend brought me from outside the town a great curiosity—a species with only two minute leaves, the solitary yellow flower produced in the middle. It belongs to Sonder's section Sphæroidea. A species of Hebenstreitia, with many small white flowers, is about 4 feet high. Hypoxis longifolia is plentiful; and a very curious moss-like plant is Psammotrophe androsacea, with small, yellowish flower-spikes, 3 inches high. I was surprised to find a very small white Nerine growing in peat on dry, rocky shelves—a most unusual locality. Other shrubs are Halleria lucida, with its small orange flowers produced directly from the main trunk; Buddleia salvifolia, Rhamnus prinoides, and one or two Rubus.

On sloping ground and dry flats a variety of plants are met with. Gerbera Kraussii has rather large white flowers; a smaller species with pink-rosy flowers is also common. An annual Nemesia, with lilac blooms, is met with, and a very large-leaved tuberous-rooted, rambling Ipomœa, with large purple flowers. In early spring a very dwarf white-flowered plant is common, looking like patches of snow; the flowers are very minute, and numerous; it is Helichrysum cæspitosum, though Harvey says that it scarcely differs from H. ericæfolium. Another plant resembling the last in habit and colour of flower is Selago phylicoides.

Amongst bulbs, we have a white and yellow Albuca, the yellow Moræa polyanthus, a very showy pink and white Brunsvigia, also B. toxicaria, and the pretty purple Babiana Bainesii. The blue Pentanisia variabilis is rather common, with an annual blue Lobelia and a yellow Sebæa. Callilepis leptophylla is a showy white-flowered herbaceous Composite, and Dimorphotheca Eckloni of the same order has large, handsome, purple flowers. Many Gomphocarpi abound, and Asclepiadeæ; one in particular given to me is, I believe, a genuine Stapelia Planti, with its wonderful corrugated, five-starred, purple flowers. There are two or three bright rosy Indigofera, and one showy, leguminous plant is Vigna angustifolia, a prostrate herb, with long, tuberous roots, and large, very handsome, bright purple flowers. Cyanotis nodiflora is also not uncommon.

In damp, marshy places there are a few plants I must mention. Plocandra purpurascens is about a foot high with very many rich purple flowers, ½-inch across, growing in masses. Lythrum Nelsoni is a heath-like shrub, 2 feet high, with spikes of small rosy blooms. Gladiolus papilio is not very common, but I once was fortunate in finding a colony of several hundreds growing within a few yards of each other. Several Tritomas, varying in colour, from pale yellow to nearly snow white, are met with. The Cape and Natal T. Urania is not seen here. A climbing Asparagus grows in damp shady places, and is much used for decoration. Richardia africana, so common in wet places in the Cape and Natal, is not found here, but its place is taken by several species with rather small cream-coloured flowers, with or without a dark spot at the base of the spathe, leaves green or white-spotted. M. Leichtlin has discovered a new species amongst some tubers sent him, and named it after the writer. The golden Richardias, Elliotiana and Pentlandi, are found in the Transvaal, but not near Johannesburg. The pink-flowered R. Rehmanni we have found to become almost pure white under cultivation, which is a pity. By the sides of streams grow Gunnera perpensa, Typha latifolia, Schizostylis coccinea, and a few dwarf sedges and rushes. Nymphæa cœrulea I have seen in ponds a few miles from the town. Striga coccinea is a dwarf plant, parasitic, I believe, on the roots of grasses in the open country, and possessing bright scarlet flowers.

Of Orchids, I am unable to say much. No Epiphytes are seen, owing to the dry, cold air. A pretty yellow Eulophia and the small, white, long-spurred Habenaria tetraptera are all I have met with up to now. Ferns are also rare, though Cyathea Dregei was once common in most sheltered places. Now and then you see an Asplenium or Cheilanthes, and still more seldom Adiantum capillus-veneris, but Pteris aquilina is common. The grasses are mostly species of Andropogon, Anthistiria, Aristida, and Cynodon. Mosses and fungi are rare. We have no Heaths, Cycads, Palms, Euphorbias, Begonias, Coniferæ, and hardly a Pelargonium, except the allied species Monsonia. As yet we have scarcely any imported weeds.

Such in brief, is the native flora of this part of the Transvaal, and I regret that I have no work on the subject to assist me, except Harvey and Sonders' *Flora Capensis*, and its continuation, which affords some information. On first coming here, I used to take short botanical trips; but of late years my duties leave no opportunity for doing this, or forming a herbarium. *R. W. Adlam, Joubert Park, Johannesburg.*

HERMAPHRODITE FLOWER OF BEGONIA GLOIRE DE LORRAINE.

Can fertile seed be obtained from this plant, either from flowers crossed by its own pollen or by that of any other species or variety?

As far as my observation goes, no female flowers are to be found till late spring or early summer, when a few appear on the extremities of the branches; at the same time I have searched in vain for a particle of pollen in any of the male flowers. Simultaneously with the development of the female flowers, a considerable number of the males produce among the stamens one, two, or even three more or less perfect pistils; quite unlike, however, those of the regular female blooms, as the stigmas are carried on the apex of a long column, and are two or three-lobed, their outer edges being fringed with innumerable delicate papillæ, which make them beautiful objects under a low power of the binocular microscope. But in no case have I discovered a trace of pollen in the imperfectly-formed stamens, nor is there the least sign of the inferior ovary of the genus Begonia. Is this an interesting reversion towards an ancestral hermaphrodite form?

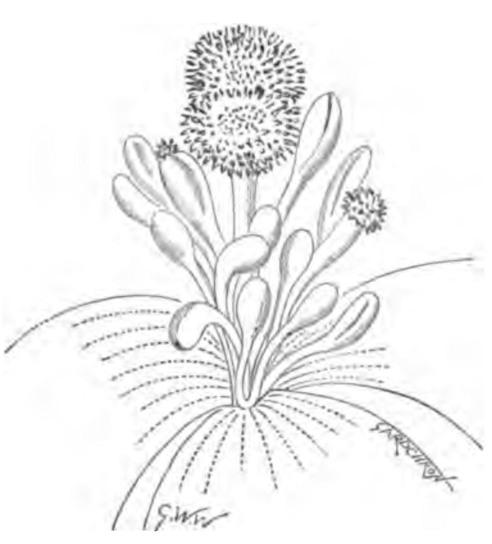

Fig. 149.—Hermaphrodite flower of Begonia Gloire de Lorraine.

It is well known that, both in the animal and vegetable world, it is characteristic of such reversions that neither the male nor the female organ is otherwise than imperfectly reproduced. I enclose a sketch of a flower (fig. 149), in which Nature has made one tolerably successful, though useless, attempt to form a pistil, together with two more abortive ones. *A. W. Wills.*

The Week's Work.

FRUITS UNDER GLASS.

By W. Strugnell, Gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge.

The Early Pot-Figs.—If these plants occupy a house to themselves, and there is no prospect of another profitable crop of fruit, remove them to another house, preparatory to placing them out-of-doors a little later. The Fig-house may then be utilised for Melons, with or without bottom-heat. The Fig-trees may be stood among indoor-plants, or in other fruit-houses where overhead-light reaches them, and where the wood may get properly ripened by the end of August, and they will be in a fit condition for a start early in the winter. Trees which will not be forced so soon, or for which accommodation does not exist, will afford a light crop if the shoots are stopped occasionally, and manure-water be afforded alternately with clear water. Failing other manure, bone-meal sprinkled on the soil has a good effect. The pots being filled with roots, much moisture should be supplied. The Fig suffers greatly from a species of scale-insect, which appears from now onwards till the leaves fall. Hot-water at 150° to 160°, as we know, is fatal to scale, and it may be safely used on the Fig; and those who may have doubts as to its efficacy or its effects on the plants, can easily put it to the proof in a small way before proceeding to use it on all the trees. A quick man with a pointed stick will clear a few trees of the scale infesting them in a short space of time. Young Figs raised from "eyes" this season should be potted as fast as the roots fill the pots, as should also older plants, if the object is to fruit them in pots. Although not absolutely necessary, it is better that the plants are freed from root-suckers as soon as these appear. A goodly proportion of broken mortar and plaster should be employed in soil in which Figs are grown.

Strawberries.—Simultaneously with the closing of the fruiting season of pot-Strawberries comes the need to make preparations for the following year, but it does not follow that I advocate immediate layering. Except for very early forcing, there is no necessity to layer any just yet, but the plants set apart for the production of runners will be benefited by having water copiously more or less often during dry weather. The best runners for early work are obtained from plantations made the previous year, and which have not been allowed to flower. I can recommend Royal Sovereign and Leader as being excellent varieties for forcing. By washing and crocking the pots whenever an opportunity occurs time is economised, and there will be less hurry when the work has to be done later on. It is a matter of opinion whether Strawberry-layers should be placed on the fruiting-pot, or on small pots or bits of turf, to be transferred to the fruiting-pots in July and August. Each has its advantages and disadvantages. For one thing, the latter course requires the proportion of two sets of pots, and the other of only one.

PLANTS UNDER GLASS.

By C. R. Fielder, Gardener to the Dowager Lady Howard de Walden, St. James's House, Malvern.

Azalea indica.—Plants which flowered early in the year having finished growing and set their flower-buds, may be placed out-of-doors in a partially sunny place to mature the wood, standing the pots on a layer of coal-ashes, or, preferably, plunging the pots in a bed of that material. Great attention must be paid to affording water to these plants during the ensuing three months that they will pass out-of-doors, sun and wind causing rapid evaporation of moisture from the soil. A syringing morning and evening will help to maintain the foliage in a healthy condition, and keep down thrips. Those plants which, having flowered late, are now making growth, may be assisted with an occasional application of weak liquid manure, particularly such of them as have not been repotted this season. If an Azalea is much pot-bound, and likely to suffer before it flowers again, it may be potted at the end of July or early in August, care being taken not to afford a large shift, or cause a renewal of growth.

Epacris.—Those plants which were cut back after flowering, and when broken into fresh growth were repotted, as advised in an earlier calendar, will have made a considerable amount of growth in the close house into which they were put, may be gradually afforded more air before being placed out-of-doors later; and when the growth is completed, they may be hardened off for a few weeks, and then placed in a cold pit or common frame for the rest of the summer. They will be the better for a syringing night and morning in fine weather, and a thin shading thrown over the glass during bright sunshine. When growth is quite complete, the lights may be altogether removed.

Ericas.—The early-flowering species and varieties now growing freely should have abundance of air during the day, and in very warm weather a small amount during the night. If the Ericas have to be grown among other kinds of plants, do not allow these to prevent sun and air reaching the Ericas on all sides, or the latter will suffer greatly. Great care is necessary in affording water to these plants, as also to Epacris; but where the drainage is in good order, and the plants are growing freely, liberal supplies are necessary and safe. To allow a Heath to become very dry at the root is fatal. Rain-water is best for them, and water impregnated with chalk about the worst. A house or greenhouse pit facing the north is more suitable for Ericas at this season than one having a southerly aspect, it being cooler and less sunny, and consequently there is less need for shading the plants.

THE HARDY FRUIT GARDEN.

By C. Herrin, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

Apricots.—Chiefly by reason of the inclemency of the weather while the trees were in bloom, the Apricot crop is a thin one. This condition of the trees is usually accompanied by a stronger wood growth than usual, which is not favourable for the prospects of a good crop. All strong shoots, especially those which form a right angle with the wall, should be pinched at the fourth or fifth leaf reckoning from the base, and such of the strong shoots desirable of being retained should be depressed at the point, in order to check development for a time at least, superfluous ones being removed altogether, leaving only those for which there is space, and leaving them at 4 to 6 inches asunder. The trees are so far healthy, and nearly free from caterpillars, and where the latter are in evidence they should be picked by hand, and destroyed. An occasional syringing with clear water in the early morning or evening will keep the trees in good order. Rapidly-swelling shoots should be examined, and the pressure of a neighbouring nail relieved by the removal of the latter, or that caused by an overtight tie rectified, or cankering of the shoot may occur. Where a good crop of fruit has been secured, the final thinning should now take place, and the fruits sent into the kitchen for consumption in a variety of dishes.

Fig Trees having now made much growth, many of the shoots will have to be removed, in order to avert crowding. The leaves are of large size, and the shoots necessarily require more space than do those of other trained fruit-trees. The small laterals should be rubbed off, and some young shoots coming from the base of the tree trained in, to take the place of those that have become generally fruitless, excepting towards the points. Train-in the shoots not less than 6 inches apart, and nip out their points just beyond the young fruits if further extension be undesirable.

General Work.—During hot and drying weather affording water to plantations of Strawberries, Raspberries, and indeed to fruit-trees generally, will be very necessary work; and if newly-planted or severely root-pruned trees, and the rows of Raspberries have not been afforded a mulch of half-rotted manure this should be attended to forthwith, and water copiously applied soon afterwards, i.e., before its manurial properties have had time to evaporate.

THE FLOWER GARDEN.

By A. Chapman, Gardener to Captain Holford, Westonbirt, Tetbury, Gloucester.

Carnations and Picotees.—The flower-spikes of those plants growing in borders and beds, if the plants are intended for affording effect, should be tied to neat stakes, making the ties sufficiently loose to let the spike grow upwards without crippling it. When the plants are grown merely for affording flowers, it is a saving of time to support the stems with the sprayey tops of peasticks or of the birch placed between rows. This method if applied to Pinks, and the white and double crimson Cloves, enables the flowers to be readily cut, and keeps them clean. Carnations, &c., in light soils, should be frequently afforded diluted drainings of the cow-stall mixed with some fresh soot, given in a clear state, not muddy; or a sprinkling of bone-meal may be afforded. With this kind of treatment, finer flowers, and stronger "grass" for layering are obtained. The delicate pink-coloured varieties, such as the Duchess of Fife, lose their colour soon if exposed to much bright sunshine, and they should be shaded during the sunnier hours. In order to have fine Carnation blooms, the buds should be thinned to two or three on a shoot, each with a footstalk.

Gladiolus.—If planted in beds by themselves, let the ground be kept free from weeds, and if it be of a heavy nature the surface should be often stirred by the Dutch-hoe. In light soils frequent applications of water and a mulching of horse-droppings to the depth of 3 inches, spread evenly over the surface, should be afforded. To ensure that no accidental loss of flower-spikes occurs, the plants should be provided early with stakes, leaving these at full length till the blooms commence to show, when they should be shortened back to the height of the lowest flower in order to avoid the bruising and rubbing of the blooms by the wind forcing the flower-spike against the stake.

Vases and Tubs, when planted with bedding-out or other plants, have a pretty effect on steps, terrace-walls, and margins of turf, and on balconies, or as "dot" plants on the lawn, or plunged in flower-beds. The bitter and sweet Oranges, Oleanders, Brugmansias, Sweet Bay, Myrtles, and Portugal Laurel, will live in good health for years in tubs with ordinary care, requiring but little protection in the winter. Though it is usual to clip these subjects into rigid shapes, they are more beautiful when grown naturally, with just a little trimming with a knife when inclined to become lopsided or of too unwieldy a size. Such plants as Agapanthus, Agaves, Hydrangeas, Fuchsias, and Marguerites, form good sized masses, and can be placed in aspects near the roots of trees where beds could not well be formed. Tubs and vases look best when filled with plants of a good size, and sufficient mould employed as will carry them through the season without loss of foliage. Loam and leaf-mould make a suitable compost. The tubs, &c., must be well drained and made quite clean by scrubbing with hot water. In the course of the season, the tubs, &c., get filled with the roots of the plants, and it is then necessary to pay very strict attention to affording water, or the plants will suffer seriously. Where the soil is not chalky, Rhododendrons are successfully grown in tubs, provided peat and sand be used in planting them; or even in chalk districts, good results are attainable if only rain-water be afforded them. Ornamental baskets and large vases have a good effect when filled with foliage plants and flowering plants of pendent habit, and planted near the sides.

Hardy Fernery.—It is seldom at this season that we get rain in sufficient quantity to reach the roots of Ferns, and copious supplies must be afforded them by means of a water-pot or hose, especially to such moisture-loving plants as Osmundas, Polystichums, Scolopendiums, and all Ferns which form a dense canopy of fronds. It does the plants good to sprinkle the fronds morning and evening in hot weather.

THE ORCHID HOUSES.

By W. H. Young, Orchid Grower to Sir Frederick Wigan, Bart., Clare Lawn, East Sheen.

Cattleya Warscewiczii, syn. C. gigas.—This plant, as it goes out of flower, pushes forth roots at the base of the newly-made pseudo-bulbs, and this is a proper moment for re-potting or surfacing the plant, which, if delayed much, are apt to prove injurious to the plant. If the plant can be conveniently suspended, a pan is best, otherwise, use an Orchid-pot. Afford the plant ample drainage by placing most of the crocks erect, use the best fibry peat, and but little sphagnum-moss; afford water sparingly till the roots have seized upon the potting materials, and if moisture should collect between the sheathing bracts and the pseudo-bulbs, carefully unfold the former, so that it may evaporate, as if allowed to remain the pseudo-bulb may be lost.

Cattleya aurea and C. Rex.—When the flower-sheaths appear in the new growths more water is required by the plant, as also in the case of C. × Hardyana and C. Massaiana; and when, as in the case of C. Warscewiezii, root action occurs, re-potting, &c., should be performed.

Lælia albida.—This species will now be making new roots, calling for fresh rooting-materials. For this plant shallow perforated pans are best, and these should be hung in a light and airy position in the Mexican-house. The drainage of a pan must be ample, and the surfacing and potting-mixture should consist of peat and sphagnum moss. It is a plant requiring very little moisture, and, excepting when just developing its growths, but little should be afforded. Lælia autumnalis is an Orchid that requires similar treatment to the last named, and L. furfuracea is a cool-house species which may be hung near a ventilator, in a light house.

Lælia anceps.—Varieties should now be kept well-moistened at the root with the syringe and the watering-pot, and exposed to a good deal of sunlight except during the brightest part of the day, with abundance of air afforded, and every means taken to encourage a sturdy growth.

Dendrobiums thyrsiflorum, densiflorum, Farmeri, and Schröderæ.—These plants should now be placed in a growing atmosphere, and when the roots appear at the base, afford the plants new material. Until this time arrives, scarcely any water should be applied; but afterwards the compost should be kept moistened, and the undersides of the leaves syringed twice daily in bright weather. When the pseudo-bulbs are grown to full size, remove to a suitable position, where there is more light and air, affording sufficient water to encourage root-action. Do not expose the plants to draughts, or spotting of the leaves will follow.

D. moschatum and D. fimbriatum.—Apply fresh material to the plants, and increase the supply of water at the root. The plants may remain in the East India-house permanently; but if space can be found for the former in a slightly cooler and drier house, it may be removed thereto when the growths have attained their limit.

THE KITCHEN GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

Tomatos in the Open.—The plants, whether grown against walls or fences, or fastened to stakes, should be made secure, laterals frequently trimmed off, and very vigorous leaves reduced in size; excepting where the rooting space is small, then the laterals only should be removed. The plants must not suffer lack of water at the roots, otherwise the flowers will not set satisfactorily. I have tried various methods to induce the flowers to set, and incidentally I have found that dry soil was the cause of many of my failures. When a good set is obtained, place a mulch of decayed manure over the roots, and freely afford liquid-manure alternately with clean water.

Asparagus.—From the present time the cutting of Asparagus-heads should cease generally in the South, and the beds receive a dressing of agricultural-salt, nitrate of soda, guano, or fish-manure, or failing these, of farmyard liquid-manure. The artificials should not exceed at one dressing 2 oz. per square yard. If heavy rain fall, no water need be afforded, otherwise they must be washed down to the roots by a thorough application of water. All weeds should be cleared off the beds before anything is applied. Keep the land between the rows of seedlings hoed frequently, and failing an abundant rainfall apply water which has been warmed by exposure to the sun.

Scarlet, and other Runner Beans.—The rows of plants should receive their stakes before the bine has run much, and a thick layer of manure along the side of the rows if the land be light of texture. If it be found dry on testing it, apply water plentifully, repeating the application if the weather keeps dry and hot, in order that the flowers may set satisfactorily, dryness at the roots being one cause of failure to set their flowers. Let the last sowing be made forthwith in well-prepared and moistened trenches, and before sowing the seed steep it for a few hours in water.

Beetroot.—The main crop of Beetroots should be singled, the plants being left at about 8 inches apart. As some of the plants left for the crop are sure to be loosened, however careful the workmen may be in thinning, a good application of water should follow the job, in order to settle the soil about them. Blank spaces in the lines may be filled up by planting thinnings that are in a perfect condition. If it can be managed, the whole of this sort of work should be carried out in showery weather.

Remarks.—The dry weather is telling injuriously on most crops. Those gardeners who have made preparations to meet a drought by heavily manuring and deep-trenching the land, will now reap their reward in vigorous plants, &c.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	June 24	Windsor Rose and Horticultural Society's Show. Royal Botanic Society, Meeting.
TUESDAY,	June 27	Royal Horticultural Society Committee (special prizes for Roses).
WEDNESDAY,	June 28	York Florists', Exhibition of Roses. Rose and Horticultural Shows at Richmond, Croydon, Bath, Maidstone, Reading, and Ryde, I.W. Annual Dinner of the Gardeners' Royal Benevolent Institution.
THURSDAY,	June 29	Royal Horticultural Society of Ireland, Exhibition. Rose and Horticultural Shows at Sutton, Canterbury, and Norwich.

SALE.

FRIDAY,	June 30	Imported and Established Orchids at Protheroe & Morris' Rooms.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period June 11 to June 17, 1899. Height above sea-level 24 feet.

Remarks.—The weather has been generally dull, with drying winds from the north and east, with very cold nights.

Average Temperature for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—62·4°.

Actual Temperatures:—

London.—*June* 21 (12 P.M.): Max. 73°; Min. 58°.

Provinces.—*June* 21 (6 P.M.): Max. 68°; Min. 54°, Sumburgh Head.

Close, dull; some rain.

Malcolm Dunn Memorial.

It is often said that a man's best memorial is to be found in the work that he leaves behind him. However true that may be as a rule, it admits of many modifications. The case of Malcolm Dunn is one of them. No man worked in his time, and in his way, more indefatigably than he for the advancement of horticulture and forestry, and the welfare of all connected with them. And yet now that his active brain and warm heart are still, what is there to show for all the work he did? Little or nothing! little or nothing, that is, that is tangible. Little or nothing which will appeal to the sympathies of the next generation. We cannot expect that our successors who will know of Malcolm Dunn only as a name, will feel the same sense of a great loss that we do who saw what he did, and what manner of man he was.

Dunn wrote no books—his articles, which were numerous, were always unsigned, he did not advertise himself or seek to further his own interest in any way. He worked for the good of the cause, and that was enough for him. But this reticence on his part only offers an additional inducement to us to do for him and for his memory that which he would not have done himself. A few short years and his name will be only a name, unless we do something to perpetuate the memory of his good works. We have two strong inducements to do this—the one is common gratitude: we are grateful to such a man for all that he did; the other is the recognition of the example he set us. We have our duties to perform, and he has set us an example that we shall do well to follow. Specially we shall do well to do something that will be commemorative—not of the man, that, we are sure, would have been distasteful to him; but of the work that he did, something that will tend in some way or another either to the promotion of the art he loved so well, or to the lightening of the load of pain and trouble that needs must often fall upon its practitioners.

The Societies with which Mr. Malcolm Dunn was especially associated have appropriately taken joint action with a view to do honour to the memory of the man who so disinterestedly exerted himself in all that concerned the welfare of horticulture. The joint committee has issued the following appeal, which it is to be hoped will be heartily responded to:—

"Malcolm Dunn Memorial Fund.

"The news of the sudden death of Mr. Malcolm Dunn, on 11th May, at Dalkeith Palace Gardens, where he had been gardener for nearly twenty-eight years, must have come upon all who knew him as a great shock.

Although a gardener by profession, his interest did not end there. Horticulture, Botany, and Arboriculture are to-day all reaping the benefit of his great energy and devotion.

Looking to this general interest displayed by Mr. Dunn, it has been agreed upon by the Royal Caledonian Horticultural Society, the Botanical Society of Edinburgh, the Royal Scottish Arboricultural Society, and the Scottish Horticultural Association, with all of which he was intimately identified, to unite in issuing a joint appeal to the many friends of Mr. Dunn throughout England, Scotland, and Ireland, for Funds to perpetuate his memory; and it is proposed that, after erecting a suitable monument in Dalkeith cemetery, the balance should be devoted to charitable and educational objects in connection with horticulture and arboriculture.

In issuing this appeal, the councils of the four societies feel assured that there are very many who will gladly join in raising such a memorial as is proposed, and thus testify to their appreciation of Mr. Dunn's worth, and to the kindly help and advice which he so freely gave.

Subscriptions will be received and acknowledged by any of the undersigned, in name of the respective societies, P. Murray Thomson, Secretary, Royal Caledonian Horticultural Society, 5, York Place, Edinburgh; James A. Terras, Assistant-Secretary, Botanical Society of Edinburgh, 21, Teviot Place, Edinburgh; Robert Galloway, Secretary, Royal Scottish Arboricultural Society, 5, St. Andrew Square, Edinburgh; Robert Laird, Secretary, Scottish Horticultural Association, 17, Frederick Street, Edinburgh."

The Shading of Glasshouses.

Now that we have approached the warmest part of the summer, it is a question that each gardener must settle for himself, how much or how little shading is beneficial to his fruit-trees, Vines, Pine-apples, Melons, and Cucumbers under glass. A good deal depends on the construction of the houses and pits, their aspects, the latitude and altitude of the place. That, where sunshine is intense and long-continued, some sort of portable light shading-material benefits the various plants after this date, goes without saying, and should be afforded, say, from 10.30 A.M. to 2.30 P.M., taking it off the glass whenever the sky becomes in the least degree cloudy.

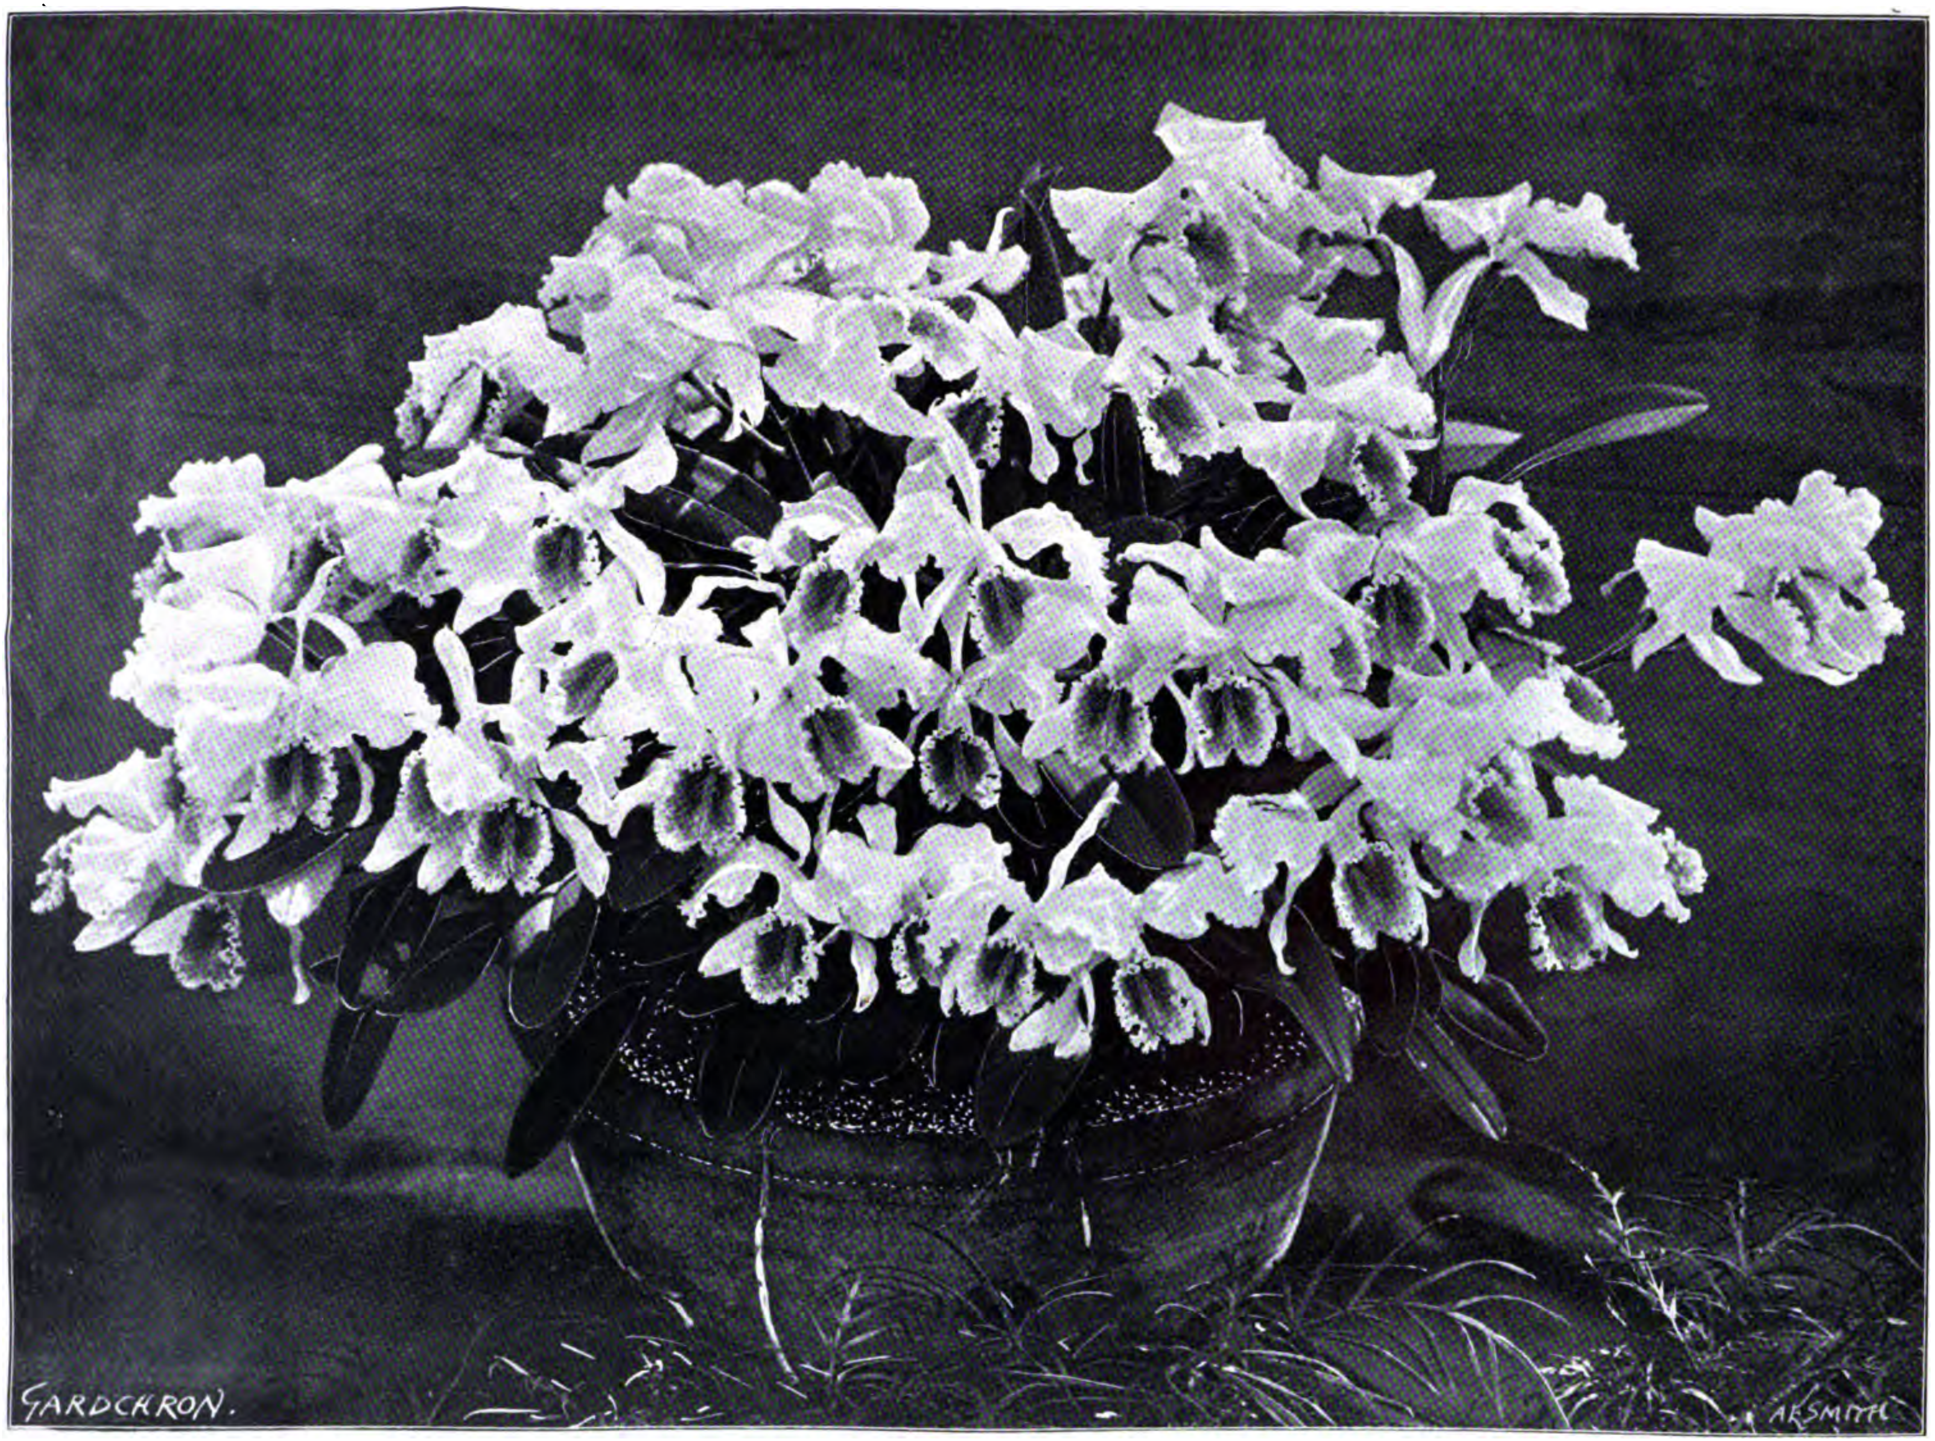
During the prevalence of bright sunshine and the hours of greatest heat, the evaporation of moisture from the plants and from the soil is greatest, and the process is, of course, accelerated by the glass coverings; hence the absolute necessity for repeated damping down of walls and paths, for unless some kind of equilibrium be brought about, the plants cease to grow satisfactorily. We know from experience that shading and damping down may be carried to excess, and it is probably due to this fact that the Melons of the present day are generally deficient in flavour, that Vine foliage is sometimes warty and flabby, and that fungous diseases are common on Tomatos and Cucumbers. We have, each for himself, to discover the happy mean in shading and damping down, for although, apparently, these are matters of great simplicity, they cannot be entirely taught by Calendar or press writers. How often has the writer of this note had to rush away from some important job in the flower garden or kitchen garden, maybe, to put on or take off shading and air in Pine, Melon, and Cucumber and plant-houses and pits, or from the never to be too highly valued contents of the propagating-frames standing on hot-beds!

Vines and Figs will withstand almost any amount of sun-heat that we get in this country—or in Europe, for that matter—if attention be paid to timely ventilation, beginning in summer weather at 7 or 7.30 A.M., by affording what is understood by a "chink of air" at the top of the houses. Much of the scalding of berry and leaf brought to our notice is caused by lack of attention to this one point. During the fitful months of March, April, and May, the risk of scalding is greatest, the foliage being extremely tender, and the bursts of sunshine so erratic that the attention of the gardener dare not be relaxed for a quarter-of-an-hour in the period from 7 A.M. to 3 or 3.30 P.M.

Provided the glass is of a good quality, and the ventilation what it should be, no scalding will occur in a vinery built according to either old or new fashions. Even without damping down it would not occur.

In Pineapple culture in the south and midland counties, scrim-shading should always be used during the hottest weather from the end of May till the beginning of August; less over plants with ripening fruits than over suckers or successions, or plants about to show flower. But in the case of these plants even scrim should not be put on earlier than 10.30 A.M., nor kept on later than 2 P.M., with air given to keep the degree of warmth at about 80° to 90°, according to the age of the plants.

If Cucumbers are grown by the so-called express method—that is, with much heat and moisture, and scarcely any ventilation—the glass is so bedewed with moisture during the day that burning seldom occurs; but where a



Cattleya Mossiæ, with 65 Flowers, from the Collection of Lily, Duchess of Marlborough.

less unnatural system is adopted, a thin shading is of benefit to the plants—as also for Melons, unless the pits or houses are very roomy ones, when shading is better dispensed with, and the temperature regulated as far as need be by ventilation only.

Our experience with Tomatos is, that shading is an evil, as is an over-moist atmosphere in the structure in which the plants are grown. A moderately hot, dry treatment, with not unlimited application of water to the root, suits the plant best; in fact, just that which would breed red-spider in most other plants.

Our old friend, the bast-mat, is not much in use in modern gardens; still, it has its uses. It is handy, if there be no wind to waft it to a distance, for throwing over a plant or batch of plants in flower, or some newly-potted, in a stove or greenhouse, or in hot or cold pits, when perhaps total shading of the structure would be undesirable; otherwise, its value as a shading material has departed, with the blue apron and the head gardener's stove-pipe head covering. As shading for Melon, Cucumber, and Pines, the bast-mat is an abomination. The slat or split bamboo shading, easily applied when fixed to rollers, is one of the best and most enduring of these contrivances.

CATTLEYA MOSSIÆ (see Supplement).—Cattleya Mossiæ is one of the best known and largest-flowered species of the whole genus; it is, however, seldom seen in such vigorous health as shown in our illustration. The plant in question is not a newly-imported one, it having been in the Deepdene collection for several years. It is a very fine, healthy specimen, and measures just over 3 feet across; altogether, there were sixty-six fully expanded flowers. The variety is a very good one, but unfortunately the brilliant colouring of the lip cannot be reproduced by photography. The plant is to be named Cattleya Mossiæ var. Lily Duchess of Marlborough, and to her we are indebted for the opportunity of giving this illustration.

ROYAL HORTICULTURAL SOCIETY.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, June 27, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. On this occasion special prizes will be offered for Roses; and at 3 o'clock, a lecture on "Some of the Plants Exhibited," will be given by the Rev. Prof. GEO. HENSLOW, M.A.

—— Exhibition of Hybrid Plants at Chiswick, Tuesday, July 11, 1899. In connection with the International Conference on Hybridisation, the following Awards will be made, viz.:—1. A Veitch Memorial Medal to the raiser of the best new fruit intentionally raised by cross-breeding or hybridisation in Great Britain, and never previously exhibited. 2. A Veitch Memorial Medal to the raiser of the best new flower (Orchids excluded), intentionally raised by cross-breeding or hybridisation in Great Britain, and never previously exhibited. 3. A Veitch Memorial Medal to the raiser of the best new Orchid, intentionally raised by cross-breeding or hybridisation in Great Britain, and never previously exhibited. 4. A Veitch Memorial Medal to the raiser of the best new vegetable, intentionally raised by cross-breeding or hybridisation in Great Britain, and never previously exhibited. 5. A Veitch Memorial Medal to the raiser of the best new fruit, intentionally raised by cross-breeding or hybridisation out of Great Britain, and never previously exhibited. 6. A Veitch Memorial Medal to the raiser of the best new flower (Orchids excluded), intentionally raised by cross-breeding or hybridisation out of Great Britain, and never previously exhibited. 7. A Veitch Memorial Medal to the raiser of the best new Orchid, intentionally raised by cross-breeding or hybridisation out of Great Britain, and never previously exhibited. 8. A Veitch Memorial Medal to the raiser of the best new vegetable, intentionally raised by cross-breeding or hybridisation out of Great Britain, and never previously exhibited. The above Medals will only be awarded should the exhibits be considered sufficiently meritorious, and the result of intentional, not accidental, cross-fertilisation. Exhibitors must give full details in writing as to parentage, and record any other points which may assist the Judges. 9. A Williams' Memorial Medal to the best collection of hybrid and cross-bred plants. *W. Wilks, Secretary.*

HORTICULTURAL CLUB.—At the usual monthly dinner of the Club on June 13, the chair was occupied by Mr. HARRY J. VEITCH, vice-chairman of the Club. The chief business in hand was the arrangement for the dinner to be given to the distinguished foreign visitors who are expected to attend the Hybridisation Conference. The dinner will be given on Tuesday, July 11, and the chair will be occupied by Sir J. D. T. LLEWELYN, Bart., M.P., chairman of the Club.

ROSE SHOW FIXTURES.—Mr. Edward Mawley wishes us to acquaint our readers with the facts that the Rose Show at Newcastle-on-Tyne, will be opened on July 19, that at Liverpool on August 3; and that the date of the Eltham Rose Show is changed from June 29 to July 13.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The sixtieth anniversary festival dinner of the Gardeners' Royal Benevolent Institution will take place on Wednesday next, June 28, at the Whitehall Rooms, Hôtel Métropole, at 6.30 for 7 o'clock precisely, when the Chair will be taken by the Rt. Hon. the Earl of DERBY, K.G., G.C.B.

THE HYBRIDISATION CONFERENCE.—In view of the great importance of the subject, we shall probably commence, in our next issue, a series of notes by various writers, on the development by means of cross-breeding of several of our garden flowers, and a number of portraits of representative men who have been or are instrumental in the improvement of our flowers and fruits by the practice of cross-breeding or hybridisation. The meetings of the Conference will be held at Chiswick on July 11, and on the following day at the Westminster Town Hall.

"FLOWERS AND FLOWER-CULTURE" (The Every-day Help Series). By H. W. WARD (London: Walter Scott, Limited).—The scope of this little book will be understood when it is stated that it is divided into chapters dealing with the flower-garden, bedding-plants, herbaceous plants, the greenhouse, Chrysanthemums, Roses, room and window plants, marketing flowers, bees in the garden, and propagating plants respectively. Mr. WARD has a practical knowledge of his subjects beyond that of most people, and he writes clearly and plainly, and with an appreciation of the requirements of his readers. His guide contains practical hints for the horticulturist, and in many cases the names of the best sorts of plants for special purposes are given. The intention is, evidently, not so much to instruct the experienced professional as to furnish the amateur with useful reminders, arranged in a form convenient for reference, and yet unencumbered with wearisome detail.

PROLIFEROUS ROSE. — Messrs. BRAYLEY & SONS send us an example of prolification in the Rose. The hep or pistil is entirely absent; the sepals, petals, and stamens are normal. In the centre of the flower is a young shoot, terminated by a flower. The case is by no means an uncommon one, but is always interesting to those concerned in the structure of the flower.

THE "FLORA" CHARLOTTENBURG. — The "Flora" Garden, whose existence dates from the "Founding epoch," and which was laid out on the pattern of the establishment of the same name at Cologne, and the "Palmen Garten" at Frankfort, but like the first without succeeding in exercising an effect upon horticulture, and becoming merely a place of public amusement, has been sold for building purposes, and the company dissolved.

DECAYED TWO-YEAR-OLD PINE NEEDLES.—It would at first hand be a poser to say to what particular use decayed Pine needles could be usefully put, beyond being placed in a heap in a moist place or under the shade of trees to still further decay, and be at length converted into leaf-mould. A correspondent, writing in *Gardening*, a horticultural journal published at Chicago, states that he buried some Hydrangeas one foot deep in two-year-old Pine-needles as a protection against frost, and found in the spring, on uncovering the plants, that the Hydrangeas had pushed forth a mass of roots into the heap of Pine-needles. In undecayed needles it may be stated that no plants ever put forth roots; and it would appear that gardeners have in decaying Fir-needles an admirable rooting material in which to layer Rhododendrons, Kalmias, Andromedas, and other evergreen and deciduous plants with the certainty of obtaining good results.

FLOWERS IN SEASON.—We have received from Mr. JOHN GREEN, Norfolk Nurseries, Dereham, some spikes of his new everlasting white Pea, Lathyrus latifolius albus grandiflorus, and which last August was awarded a First-class Certificate by the Royal Horticultural Society; and also last July a First-class Certificate by the Norfolk and Norwich Horticultural Society. The following extract is from the journal of the Royal Horticultural Society, vol. xxii, part 3, page cxlix. "Award of Merit to Lathyrus grandiflorus albus (votes unanimous), from Mr. GREEN, Dereham. A vigorous-growing seedling everlasting Pea, with stout spikes of unusually large pure-white flowers, an exceptionally free-flowering variety." The spikes and the flowers were very fine and of great decorative value, either cut or growing. It is not yet in commerce, but will be sent out as soon as ever sufficient stock can be raised.

A DISCLAIMER.—In a review of LORD DE TABLEY'S *Flora of Cheshire*, C. WOLLEY-DOD is named as a recent contributor to the *Cheshire Flora*. The person intended is not myself, but my son, Major ANTHONY WOLLEY-DOD of the Royal Artillery, who has done a good deal of work in our native Flora. *Charles Wolley-Dod, Edge Hall, Malpas, June* 18, 1899.

RHODODENDRONS IN REGENT'S PARK.—Messrs. JNO. WATERER & Co., Bagshot Nurseries, Surrey, have again this season made an exhibition of Rhododendrons in a marquee in the Royal Botanic Society's Gardens at Regent's Park. On Monday and Tuesday last special invitations to view these abundantly-flowered plants were accepted by upwards of 2000 persons. The site of the exhibition is the same each year, and the beds, some high, some low, and of varying shapes and sizes, are also the same. What variety is introduced, therefore, is due to the manner in which the beds are planted. The site could indeed be hardly laid out to better advantage for such an exhibition, and an effect is obtained from the whole, viewed from any part of the marquee that is a capital advertisement of the beauty and showiness of the Rhododendron. These hardy Rhododendrons have been crossed and re-crossed with each other so many times and in so many ways, that the variety obtained is such that to name each one must entail confusion that in some degree is not necessary. But extra good varieties must be named in order to perpetuate them with certainty, and for commercial purposes. Pink Pearl is one of the very best Rhododendrons, but this novelty did not happen to be in flower. Gomez Waterer is almost as large in the flower as Pink Pearl, the colour being white or palest blush, with bright green spots upon the upper petal. A few other noticeable varieties in the collection were Madame Carvalho, pure white with green spotting; Queen, white, upper petal marked with buff; Kate Waterer, rich clear rose colour, the upper petal having green spots on a white ground; Countess of Tankerville, rose, with a whitish centre; Duke of Connaught, a capital white variety, with yellow spotting, very distinct; Michael Waterer, a bright crimson self; B. W. Elliott, clear rose colour, with deep spotting; W. E. Gladstone and Lady Ellen Cathcart, both rose-coloured flowers; Mum, a white, very free flowerer, producing splendid trusses, and probably one of the best for forcing in early spring; Concessum, rose-coloured with lighter centre; T. B. Hayes, white, with chocolate-red blotch, suggestive of the stains on a Pelargonium; Helen Waterer, bright red with white centre, a fine variety; and Album grandiflorum, white with yellow spotting, an old but valuable variety. The display will soon be past, but is a little later than the show in the Bagshot Nurseries, owing to the retarding effect of moving the plants when in bud, and to the tent protecting the flowers from bright sunshine.

PUBLICATIONS RECEIVED.—From the Michigan State Agricultural College Experiment Station, Bulletin 168, February: *Michigan Fruit List*, L. R. Taft.—Also Special Bulletin No. 11, March: *Frozen Trees and their Treatment*, L. R. Taft.—*Finland*, an English journal, devoted to the cause of the Finnish people. No. 1, June. Edited by C. H. Perrott (offices, 106, Victoria Street, S.W.).—*Halifax Naturalist*, Vol. IV., No. 20, June, contains papers on the Autumn Crocus, by W. B. Crump; Shibden Hall (illustrated), by John Longbottom; a biographical note on the late Henry Thomas Soppitt (with portrait); also as an inset, some pages of the Flora of Halifax, by W. B. Crump.—*Schedule of the Exhibition of British-Grown Fruit* to be held by the Royal Horticultural Society at the Crystal Palace on September 28, 29, and 30 — *Album des Orchidées*, par H. Correvon (Paris: Doin)

PLANT PORTRAITS.

GLADIOLUS QUARTINIANUS SUPERBUS, *Garden*, June 3, 1899. See *Gardeners' Chronicle*, December 31, 1898, p. 467.

SALVIA GONDUTI, Benth.—Flowers crimson, in terminal racemes; *Revue de l'Horticulture Belge*, June.

TREMANDRA ERICOIDES VAR. HIRSUTA, *Revue de l'Horticulture Belge*, June.

TEA ROSE SOUVENIR DE PIERRE NOTTING, raised by Messrs. Soupert & Notting, Luxemburg, from seed sown in May, 1894. The parents are Maréchal Niel ♀, Maman Cochet ♂. Colour of flower golden yellow, with a tender reddish shade upon it. Very free, a vigorous grower, with a long, filbert-shaped bud. Good for forcing, as the second growth reaches a length of 8 to 12 inches. Figured in the *Deutsche Gartner Zeitung*, June 17, 1899.

IRELAND.

DUBLIN WEATHER.

OUR gardeners are complaining they are in want of rain, the tropical weather experienced of late having told severely on all kinds of crops. A change set in a few days ago, and instead of the bright sunshine, we have had an occasional shower, and plenty of dark threatening clouds; but the rain was of too brief duration to be of much benefit to plants, and the expected is deferred. Farmers around Dublin are enabled to forward a large consignment of Potatos to market, the warm weather having told immensely in their favour, and the early arrivals are of a good size and flavour, an unusual occurrence in Ireland.

THE ROYAL HORTICULTURAL SOCIETY OF IRELAND.

The usual monthly meeting of the Council of the above Society was held on Tuesday afternoon, the 13th inst., at their offices, 61, Dawson Street. Major Domvile, J.P., occupied the chair. The following members of the Council were present:—Surg.-General Beaumont, M.D.; Mr. Robertson, J.P.; Mr. D. Ramsay, Mr. H. Smallman, and Mr. W. H. Hillyard (secretary). After the minutes of the last meeting were read and duly signed, the principal item of business before the Council was to settle the pending final arrangements for the forthcoming Rose show. After a brief discussion, the arrangements were completed. The secretary then submitted a list of names with a view to their being elected members of the Society, which was sanctioned.

IRIS BULBS DISEASED.

Two years ago some diseased bulbs of Iris reticulata were sent to the *Gardeners' Chronicle* from Southport for examination, but owing to the material being immature, nothing was done at the time.

During the present season the same disease, occurring on the same host, has been received from two widely separated localities. The parasite is a fungus which forms blackish patches on the surface of the bulb; these patches are at first small in size and few in number, but gradually increase in size and run into each other, when the bulb presents the appearance of having been charred. At first the fungus is quite superficial, and the bulb can be saved if prompt measures are employed; finally, however, the mycelium of the fungus permeates throughout the tissues of the bulb, which soon decays.

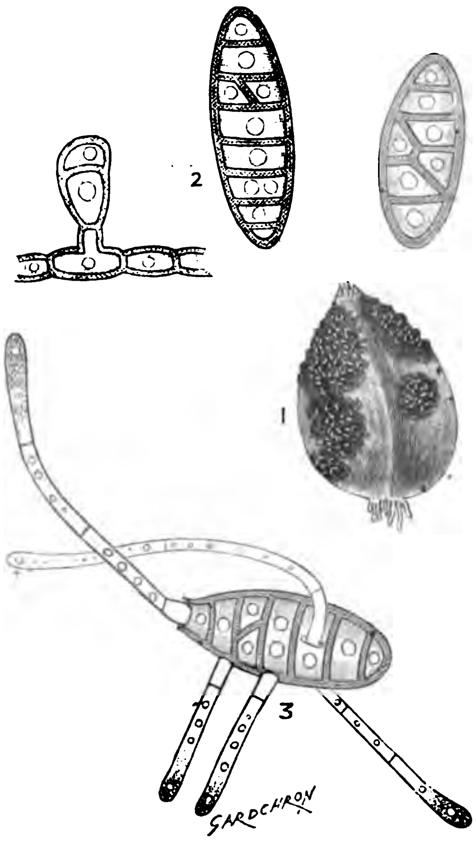


FIG. 150.—DISEASE OF IRIS: MYSTROSPORIUM ADUSTUM.

1, Bulb of Iris reticulata, diseased; nat. size.
2, Spores in various stages of development, × 400.
3, Spore germinating, × 400.

If a fragment of the black crust is examined under a microscope, it is seen to consist of brown, much branched, interwoven hyphæ, bearing myriads of very large, dark-brown spores, borne singly at the tips of short, lateral branches.

Preventive means.—If only superficially attacked, soaking in a solution of one part formalin to 400 parts water for one hour, will destroy the fungus without at all injuring the bulbs. Bulbs that are badly attacked should be burned, and as the black crust breaks away readily from diseased bulbs and remains in the ground, it would not be wise to use such infected ground for bulbs for some time to come.

The following is a technical description of the fungus which proves to be an undescribed species, allied to—

Mystrosporium alliorum, Berk., a parasite on cultivated Onions; the latter, however, differs in the smaller, minutely-warted spores.

Mystrosporium adustum.—Maculis crustaceis, indeterminatis, facile secedentibus, colore nigro; hyphis in fasciculos densos congestis, septatis, ramosis, fuscis, hic illic inflatis; conidiis solitarie acrogenis, elliptico-fusoideis, 5—7 septato-muriformibus, ad septa non constrictis, umbrino dein opacis, glaber, 46—60 × 20—22 μ. *Geo. Massee.*

THE DARWIN STATUE AT OXFORD.

A LIFE-SIZED statue of Charles Darwin by Mr. Hope Pinker, presented to the University of Oxford by Professor Poulton, Hope Professor of Zoology, was unveiled at the University Museum on the 14th inst., and Sir Joseph D. Hooker delivered an address upon the occasion.

Sir Joseph Hooker said the fact of their having commenced their scientific careers under very similar conditions favoured the rapid growth of a bond of friendship between Mr. Darwin and himself. We both of us, he continued, immediately after leaving our respective Universities, commenced active life as naturalists under the flag of the Royal Navy; he as a volunteer eight years before me, who was an official. We both sailed round the world, collecting and observing often in the same regions, many of them at that time seldom visited and since made accessible to science by his researches—the Cape Verd Islands, St. Helena, Rio, the Cape of Good Hope, the Falkland Islands, Terra del Fuego, Tasmania, and New Zealand. On returning to England we both enjoyed the rare advantage of the counsel and encouragement of one of the greatest leaders in science of the time—Mr., afterwards Sir Charles, Lyell.

The *Journal of Researches into the Natural History and Geology of the Countries Visited during the Voyage of the Beagle*, was then passing through the press, and the proof-sheets lent to me for perusal, because I was then preparing to accompany Sir James Ross as a naturalist on the Antarctic expedition (1839-42). At that particular time I was engaged in engrossing hospital duties, and I slept with the proofs under my pillow, that I might at once, on awaking, devour their contents.

Shortly after the arrival of the Antarctic expedition (in 1843), I received from Mr. Darwin a long letter, warmly congratulating me on my return, directing my attention to the importance of correlating the flora of Fuegia with those of the Cordillera, and of Europe, and inviting me to study and publish the botanical collections which he had made in the Galapago Islands, Patagonia, and Fuegia.

VISITS TO DARWIN AT DOWN.

This led to an interchange of views on the subject of geographical distribution, followed by an invitation to visit him at what he used to call his inaccessible home at Down, which was then eight or ten miles distant from the nearest railroad station. This I joyfully accepted; and then commenced that friendship which ripened rapidly into feelings of esteem and reverence for his life, works, and character that were never clouded for one instant during the forty subsequent years of our joint lives. During the many visits to Down which followed, he laid before me without reserve, not only his vast stores of knowledge, but his mature and immature speculations and theories, describing how they originated, dwelling on their influence on the progress of his researches. Among these, so long ago as 1844, was his sketch of *The Origin of Species*, which I was the first to see of the few friends to whom he ever showed it. At that very early period of my own studies I failed to grasp its full significance.

On the occasions of many other visits it was Mr. Darwin's practice to ask me, shortly after breakfast, to retire with him to his study for twenty minutes or so, when he brought out a long list of questions to put to me on the botanical subjects then engaging his attention. These questions were sometimes answered offhand, others required consideration, and others a protracted research in the herbarium, or in the gardens at Kew. The answers were written on slips of paper, which were deposited in bags or pockets that hung against the wall within reach of his arm, each of them a receptacle devoted to a special object of enquiry. To me this operation of "pumping," as he called it, was most instructive. As his health fluctuated or declined, and especially during his sharper attacks of illness, these interviews became intermittent, and on such occasions he would ask me to bring my own work with me to Down, where I pursued my studies free from the distractions of Kew, and with the advantages of his counsel and aid whenever desired. These morning interviews were followed by his taking a complete rest, for they always exhausted him. These attacks were followed by a period of what with him was the merest approach to health, and always to activity. Shortly before lunch I used to hear his mellow voice under my window, summoning me to walk with him, first to inspect the experiments in his little plant-houses, and then to take a precise number of rounds of the "sand walk," which he trudged with quick step, staff in hand, wearing a broad-brimmed straw hat and light shooting-coat in summer, and a felt-hat and warm cape in winter. This walk was repeated in the afternoon; on both these occasions his conversation was delightful, animated when he was well enough, never depressing however ill he might be. It turned naturally on the scenes we had witnessed in far-away regions, on anecdotes of our sea-faring lives, and on the discoverers in science, then, as now, hurrying onwards, and treading on one another's heels in their haste for recognition. In the evening we had books and music, of which latter Mr. Darwin was during the first few years of our friendship, almost passionately fond; it is a curious fact that music should have had in after life no charm for him—that "it set him thinking too energetically at what he had been at work on instead of giving him pleasure."

If I were asked what traits in Mr. Darwin's character appeared to me most remarkable during the many exercises of his intellect that I was priviledged to bear witness to, they would be, first, his self-control and indomitable perseverance under bodily suffering; then his ready grasp of difficult problems; and, lastly, the power of turning to account the waste observations, failures, and even the blunders of his predecessors in whatever subject of inquiry. It was this power of utilising the vain efforts of others which in my friend Sir James Paget's opinion afforded the best evidence of Darwin's genius. Like so many men who have been great discoverers, or whose works or writings are proofs of their having intellects indicating great originality, he was wont to attribute his success to industry rather than ability. "It is dogged that does it," was an expression he often made use of. In his autobiography he says of himself—"My industry has been nearly as great as it could have been in the observation and collection of facts;" and, again, "of the complex and diversified mental qualities and conditions which determined my success as a man of science, I regard as the most important the love of science—unbounded patience in long reflecting over many subjects—industry in observing fact, and a fair share of invention as well as of common sense." In this introspection he has, if my judgment is correct, greatly undervalued "invention;" that is, originality or that outcome of the exercise of the imagination which is so conspicuous in every experiment he made or controlled, and in the genesis of every new fact or idea that he first brought to light. Referring to his disregard when possible of his bodily sufferings, I remember his once saying to me that his sleepless nights had their advantages, for they enabled him to forget his hours of misery when recording the movement of his beloved plants from dark to dawn and day-break. For those other qualities of head and heart that endeared Mr. Darwin to his friends, I must refer you to the *Life and Letters*. There is only one upon which I would comment, it is that passage of his autobiography where he says, "I have no great quickness of apprehension or wit." Possibly the "of" and "or" are here transposed; whether or no, my impression of his conversation has left the opposite as characteristic of him. It is at any rate inconsistent with the fact that in arguing he was ever ready with repartee, as I many times experienced to my discomfiture, though never to my displeasure; it was a physic so thoughtfully and kindly exhibited. And I may conclude these fragmentary records with an anecdote which goes, I think, to support my view, and which I give, if not verbally correctly, as nearly as my memory of so ancient an episode permits. I was describing to him the reception at the Linnean Society, where he was unable to be present, of his now famous account of "The two Forms or Dimorphic Condition of Primula," for which he took the common Primrose as an illustration. On that occasion, an enthusiastic admirer of its author got up, and in concluding his *éloge* likened British botanists who had overlooked so conspicuous and beautiful a contrivance to effect cross-fertilisation to Wordsworth's "Peter Bell," because—

"A Primrose on the river's brim,
A yellow Primrose was to him,
And it was nothing more."

When I told Mr. Darwin of this he roared with laughter, and, slapping his side with his hand, a rather common trick with him when excited, he said, "I would rather be the man who thought of that on the spur of the moment, than have written the paper that suggested it." *Condensed from the Times.*

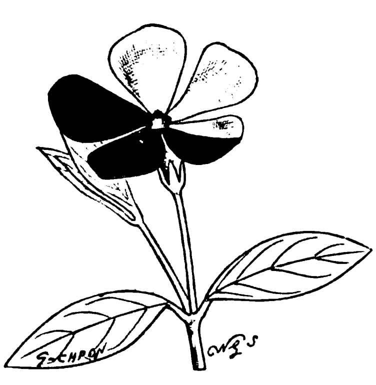

FIG. 151.—A HYBRID VINCA MINOR.

A HYBRID VINCA.

IN the old vicarage garden of Totternhoe, near Dunstable, are beds of Vinca minor, in the two varieties of deep violet and white. Amongst these two forms is a single plant with parti-coloured flowers, white and violet, herewith illustrated (fig. 151). This plant appears to be either a natural hybrid brought about by insect agency, and therefore remarkable in Vinca, or a half reversion of the white form to the original violet condition. *W. G. S.*

LAW NOTES.

JOHN SHAW *v.* R. H. HOMAN.—LANDSCAPE GARDENERS' PLANS.

AT Manchester County Court on Friday, before his Honour Judge Parry, Mr. John Shaw, F.R.H.S., landscape gardener, Ashley Road, Altrincham, sought to recover the sum of £3 3*s.* from Mr. R. H. Homan, a Manchester merchant, for plans prepared by his orders. The defence was that the plans were prepared only in competition with others, but his honour held that defendant in his letter to the plaintiff never stated that such was the case. It should have been distinctly stated that he was competing with others. He therefore gave judgment for the amount claimed, with costs.

THE STAMENS OF ORCHIDS.

MOST people, nowadays, know that the single stamen of the majority of Orchids, or the pair of stamens in Cypripedium, are the only representatives of a group which did contain, or is supposed to have contained, six members. Then, for reasons of convenience, four or five of the stamens were dropped, and the flower assumed an irregular form, instead of the regular shape it had in the first instance. Traces of the missing stamens are often visible, whilst the minute microscopical anatomy of the flower reveals traces of their existence in almost all cases. We have had the good fortune before now to see all six stamens in Odontoglossum crispum; but in the flower of which we now give an illustration (fig. 152) there are but three. The specimen sent to us was grown in the collection of Sir F. Wigan (gr., Mr. Young). All the flowers on the raceme were thus affected, one flower even had four stamens.

HOME CORRESPONDENCE.

UTRICULARIA CAPENSIS.—Plants of this minute little gem were recently found growing in a pot with Disa grandiflora, a number of which were imported from South Africa by Mr. W. Goodliffe, of Cambridge Nurseries, Worthing. Although it appears to spread freely, it could only be found in one pot out of about half a dozen. Examined by the naked eye it is not very attractive, but placed under a powerful lens a most perfect and beautiful flower is revealed, the base of the flower and hood being white, shaded with yellow. The lip is of a rich purple; there is also a band of the same colour round the margin of the hood (or upper petal), and the whole surface of the flower studded with minute crystal globules. A plant of this interesting little gem was staged at the recent Temple Show, and although the smallest exhibit there it was not the least interesting, a fact fully attested by all who had the opportunity of examining it under a magnifying glass. *A. H.*

THE SHERWOOD CUP.—Certainly it is in no sense prejudging the event to say that Mr. E. Beckett has practically won the fine cup which Mr. Sherwood placed at the disposal of the council of the Royal Horticultural Society for competition, with collections of vegetables, at the Drill Hall. That failure in securing competition was predoomed because of the conditions of the class was certain from the first. Still, absolute failure was not expected in securing fine productions, for Mr. Beckett's grand collection of fifty-three dishes of vegetables never has been equalled, much less excelled, by anyone at this time of the year. So far something has been gained that we have seen, thus finely illustrated the capacity of the British gardener to grow splendid vegetable produce, and thus make an exhibit that of its kind was by far the finest in the Drill Hall on the 13th inst. Still more the products showed the fine quality we have in vegetables even in June. When the next scene of the little play is enacted, which will be on September 12, Mr. Beckett will again be the sole representative, as by reason of failure to appear on the 13th inst., all other persons are debarred from competing. Putting up collections of fifty dishes, and without a single dish of inferior stuff, is a task that few will essay. Besides inviting in the competition unlimited collections, there was the drawback that only one prize was offered, and as only one could win it, no doubt vegetable growers were willing to allow a walk over. Not that with competition do I think anyone could have beaten Mr. Beckett in June; but in September, with collections of say twenty dishes, quite enough for any prize, the competition might have been very keen. But in August and September our leading vegetable growers have strong attractions elsewhere, very liberal and many money and cup prizes being offered all over the kingdom, and in no case probably for more than twelve dishes, and in very many for nine and six dishes only. In such cases competition is plentiful and keen. *A. D.*

KILLING AMERICAN-BLIGHT.—Mr. Moody Bell's use of a painter's-lamp for the purpose of destroying American-blight on Apple-trees seems to be employing a rather costly instrument. Some years ago, when Apple-trees were much infested with clusters of the Lackey-moth caterpillar, I employed paraffin with rapid effect, by fixing pieces of cotton-rag on the point of a long stick, dipping them into paraffin, setting them alight, then rapidly igniting or scorching out the clusters of caterpillars. Not a leaf seemed to be injured. Would not a similar appliance, run rapidly over the stems of infested trees, be equally as destructive of the woolly aphis? But after all, does this pest give much trouble to trees that are annually coated over, as far up the stems and branches as can be, with a pasty liquid of soft-soap, lime, and soot, and a little size? Such a combination laid on thickly kills the pests by literally enclosing them from air. Trees treated in this way always seem as free from insect pests as they are of moss or other vegetable parasites. I have observed that trees so treated, when they shed their dressing of this nature during the season, invariably present smooth, clean stems, void of broken or abrased bark. It is in the interstices of the bark that the woolly aphis finds a congenial habitation, and the less of these interstices or broken places found on trees the less relatively are insect pests generally. Such troubles are left to be dealt with after the trees have foliaged, when it is always more difficult to do so, although the pests are then most noticeable. Thorough washing of the trees in the autumn with almost boiling-water, followed by coatings of the solution named, would be most effective destroyers. *A. D.*

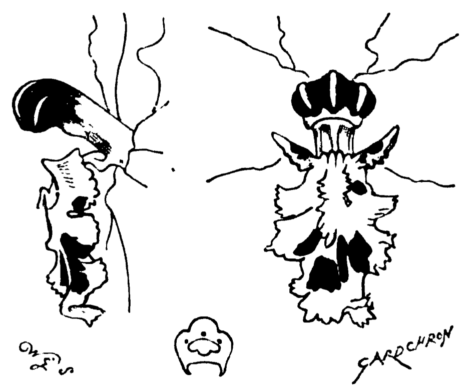

FIG. 152.—COLUMN OF ODONTOGLOSSUM CRISPUM.

(Showing three stamens instead of one only. Front view to the right, side view to the left.)

HOT-WATER, MEALY-BUG, AND MILDEW.—During my term of seven and a half years under the late Mr. Thos. Terry, gardener to Lady Giles Puller, Youngsbury, Ware, Hertfordshire, there were two very large plants of Stephanotis floribunda on wire trellises, which, with the pots, were six feet in height, and two large plants of Dipladenia amabilis, and one of Cyrtoceras reflexum, greatly infested with mealy-bug. On reference to my diary, date Jan. 17, 1857, I find that the gardener took the Stephanotis off the trellis, rolled up the trailing shoots in a coil, and then plunged them in a copper of boiling water, taking them out instantly. The plants were entirely killed as far as the water touched them, but to the surprise of everyone present, the mealy-bug came out untouched. The Cyrtoceras shared the same fate; the Dipladenias came out with the mealy-bug unharmed. The trellises were afterwards washed with Gishurst Compound, and hung on trees in the shrubbery till required the following spring; the mealy-bug was then still alive. Petroleum and other insecticides now in use were unknown; it was all picking and sponging, which after all are the safest and surest methods. For mildew on Vines the best remedy is to take ½ lb. of flowers-of-sulphur, mix into thin paste as you would mustard, then add 4 gallons of clean water, well stirring it together, and standing it in the house where it is to be used for twelve hours, that is, till quite clear; in the morning ladle-out all the clear water into other vessels without disturbing the sulphur lying at the bottom, and syringe therewith the Grapes and foliage, or whatever is affected. This is a safe cure, and leaves no stain on berry or foliage. I consider hot water a dangerous remedy. I should think as bad as using a pan of burning sulphur. *Thos. Godfrey, Hillingdon.* [Mr. Mallett, who recommended heated water for destroying mildew and mealy-bug, did not say that he used it at the boiling-point—212°, Fahr., but something less than that, say, about 180°; neither did he dip his plants into a "copper of boiling water," a proceeding which the most inexperienced gardener would know to be dangerous to plant life. He stated that the water was applied by means of a syringe; and in its transit from one place to another, and passage through the air when driven out of the syringe, it would be greatly robbed of its heat. Ed.]

FANCY PANSIES.—As "R. D." has told so clearly the story of the introduction of the Fancy Pansy into Britain, no doubt renewed interest will be felt in these beautiful hardy flowers, for of their size as plants we have very few that produce such grand blooms, so superbly marked, and coloured as Fancy Pansies do. I am induced because of this to ask for information, as to whence come into market at this time of the year in such immense numbers, such grand-flowered plants as are seen everywhere offered for sale. Do they come from across the Channel, or are they grown at home? and if the latter, are they raised from home-saved seed, or from imported seed? Also under what conditions is the seed sown and at what time, and how are the plants grown to produce such robustness and such giant and brilliant flowers? No strain anywhere gives finer, few give so fine; whilst I see plants of this description freely purchased and planted, yet I do not observe that they seem to have long lives. Does this arise from the changed conditions of culture to which subjected? are they grown during the winter in cold frames, and on very rich soil? If that be so, their robust character is explained, as is also the fact that after being planted in garden-soil for a few weeks, they seem to do so indifferently. Still, that the plants come from a grand strain there can be no doubt, and it may not be far wrong to assume that to induce them to thrive in gardens, it is needful to furnish them with culture somewhat similar to what they have enjoyed in the market-growing establishments. *A.*

A QUESTION.—Your correspondent "J. C.," at p. 400, laments the absence from modern gardens of certain flowers which were favourites of his, fifty years ago. He is also surprised that he does not see them offered in trade-lists. Having myself been familar with those plants half a century ago, I can sympathise with him, though we have much compensation in the possession of recent additions to our garden plants. I think, too, I can explain, if not justify, the disappearance of our old favourites. As botanists we can but remember with interest the charming little plant Yellow Violet, introduced by Mr. Veitch forty-five years ago, but we have now the more showy and more easily-cultivated yellow Violas for beds and borders. The "Double Walls" of those days were propagated only by cuttings, but now very fine Double Wallflowers are raised more easily and abundantly from seed, though I confess to a preference for the more compact and natural appearance of the plants we raised from cuttings. I do not remember the black-flowered Delphinium, but we see now a great variety of dark purple, indigo-blue, and brilliant light blue, all raised easily from seed. But "J. C." says, where are now the Hyacinths, Double Purple-Green Tips, Double Red Green Tips, and Double White Green Tips which, he says, he used to obtain of the late Mr. John Sutton, which I can quite believe, as this was my father, with whom I was then in partnership (fifty or sixty years ago), and I well remember the pretty Hyacinths he reminds me of, and which could still be procured in the trade if ordered. The disappearance of these old favourites is accounted for by the fact that the present day demand is for the most showy and the most free-growing of flowers for beds and borders, and the nurseryman or florist finds it to his interest to cultivate and advertise those things which best meet the public demand. It is now more than ten years since I retired from the business firm of Sutton & Sons, but the interesting enquiry of your correspondent, "J. C.," tempts me to offer a few notes to the *Gardeners' Chronicle*, with which I have corresponded from its foundation, fifty-eight years ago. *Martin Hope Sutton.*

PROSPECTS OF THE FRUIT CROPS IN SHROPSHIRE.—There is every prospect of an abundant crop of most kinds of fruit this year in Shropshire, with the exception of Plums and Damsons, and in some parts, Gooseberries. In some districts the crops of Gooseberries are very good, and in others almost a total failure, owing to the severe frosts experienced in spring. The Plum and Damson-trees were heavily laden with blossoms in spring, and gave promise of abundant crops of fruit; but the cold spring proved too much for them, and we may say there is generally a total failure. I have visited many parts of Shropshire, and only very locally could anything worth calling a crop be found; the fine gardens at Sundorne Castle, so ably managed by Mr. Phillips, the head gardener, being one of these exceptions. Here, Plums upon the walls are an abundant crop. The Apricots and Peaches—the latter especially being heavily laden with fruit; in fact, fruit of all descriptions will be very plentiful. This county is noted for its Damsons, and in good years the crop is a valuable one especially to cottagers, and the disappointment is great this year, as there was such an early promise of abundant crops. The trees also are terribly infested with the Plum-aphis, which curls up the leaves, causing crippled growth and otherwise injuring the trees. Apples and Pears are much above the average; Strawberries also are a very abundant crop, notwithstanding some of the first blossoms were destroyed by the early frosts of spring. The glorious rains we are now having will do much to secure fine fruit and a continuous supply. *A. Gaut, Shrewsbury.*

Obituary.

THE LATE J. CRAGG.—As gardener to the late A. Heine, Esq., the deceased was well known as a thorough good all-round man, a capital hand with bouquets, vases, and table-decorations, very successful with Orchids—at one show, if my memory serves me aright, he carried off every 1st prize in the open and amateur classes at Old Trafford, when competition was keener than is the case at the present time. He was a good Chrysanthemum grower and exhibitor, and had excellent taste in forming groups of plants for effect. I ever found him a pleasant companion, and a most unselfish and kind-hearted neighbour. My mind runs over those connected with some of the big shows at Old Trafford long ago, and of that number Messrs. T. Baines, W. Cole, W. Milford, G. Toll, T. Hubberstey, J. Jones, A. Beesley, G. Beddoes, B. Findlay have all passed away, the greater number, comparatively speaking, in middle age, some scarcely that; and to the number we may now add J. Cragg, who, after about fifteen years' service at Birchfield, has succumbed at the age of forty-six years. *W. Swan.*

PETER DRUMMOND.—Only a fortnight after attending the funeral of the late Mr. Kelway, occurred the sudden death at the age of sixty-six, of Mr. Peter Drummond, who had been foreman at the Langport Nurseries of Messrs. Kelway & Son for a period of twenty-six years. As a testimony to the character of the deceased gardener, we reproduce the following appreciative description of him by the firm itself—

"Mr. Drummond's death has been a severely-felt loss to us; we mourn a man of forceful intellect and inventive mind, a most clever cultivator, a charming personality, a devoted friend, and most faithful servant."

Mr. Drummond's father, writes Mr. Croucher, our valued correspondent at Ochtertyre, N.B., was gardener at this Scottish domain from 1842 to 1857, and was Mr. Croucher's immediate predecessor. The gardener there previous to Mr. Drummond remained over fifty years. Accordingly there have only been three gardeners at Ochtertyre since the year 1790. Ochtertyre is the residence of Sir P. K. Murray, Bart.

JAMES ANDERSON.—We regret to have to announce the death of Mr. James Anderson, who expired at Glasgow on June 16, at the age of sixty-seven years, after an illness extending over some eighteen months. Mr. Anderson was well known as having been gardener for many years to T. Dawson, Esq., Meadowbank, Uddingstone, N.B., where there was one of the finest collections of Orchids of the time, and in which many that are still held in high esteem made their first appearance, and notably Odontoglossum × Andersonianum and Lælia anceps Dawsoni. Mr. Anderson was a very successful cultivator, and also exhibited some very remarkable specimens, securing the very rare honour of the Lindley Medal, and many other awards. After Mr. Dawson's death, Mr. Anderson established himself near Glasgow as a landscape gardener and horticultural expert, but soon removed to the neighbourhood of Manchester, and many gentlemen availed themselves of his services as an adviser in gardening matters. He was also employed on the Epping Forest Commission, and was for many years a valued correspondent of this journal. The deceased was for the period of its short existence editor of the *Northern Gardener* at its commencement in Edinburgh, and later at Manchester. He also brought out a bulky work entitled *The Practical Gardener.*

NURSERY NOTES.

KNAP HILL NURSERY IN JUNE.

To anyone interested in Rhododendrons and Azaleas, one can imagine no better day of education and pleasure combined than a visit to the Knap Hill Nursery during the early days of June. There is not, I suppose, within the three kingdoms a place where so large an area is covered with Rhododendrons, not merely stuff for selling by the hundred, but magnificent specimens, some of which in their height and spread of branches, as well as in the thickness of their stems, may rank as small trees. As the nursery is approached from Woking Station, a foretaste of the feast of colour is obtained from the high road, whence glimpses can be caught, low in the distance, of great stretches of Rhododendrons in bloom—a scene not only very beautiful, but peculiarly striking, set, as it is, amidst the meadows and hedgerows of pastoral Surrey. When the nursery is reached there is seen stretching away through it a straight avenue, close upon a mile in length, bordered for the most part by towering masses of Rhododendrons, among which the variety album elegans is prominent in huge bushes 15 feet or so high. From this avenue we make incursions on either side, traversing quarter after quarter of the nursery, still of the finest varieties of Rhododendrons in full bloom, till we are almost bewildered by the glowing masses of colour that close in on every side. Purple of various shades is still the prevailing colour among garden Rhododendrons, but here there is every range of colour, from pure white to vivid crimson. Although some of the purples are of a distinctly blue shade, pure blue is, of course absent, just as pure yellow is.

As is well known, a great proportion of the best varieties of garden Rhododendrons originated at Knap Hill, the present head of the establishment, as well as his father and great uncle before him, being all enthusiastic breeders of new varieties. One thing to which the Waterer Rhododendrons owe their great value, is the strong strain of R. catawbiense blood that runs in them; this shows its influence especially in a greater hardiness and finer foliage than can be claimed for those in which R. ponticum preponderates. One of the most interesting plants in the nursery is the original specimen of R. catawbiense (now a huge bush), to which so many varieties owe their origin in greater or less degree. How many hundreds of thousands of plants own kinship to this one plant! But however fine the varieties that have already come from this nursery, there are others still finer which have not yet been sent out, or even named. As one threads his way amidst the labyrinth of Rhododendrons, Mr. Waterer keeps on pointing out new sorts still unchristened, which, in size of flower and truss, in vigour of foliage and habit, in richness of colour and marking, are still better than the best of those that have gone out into the world.

The same progress is being made among the deciduous so-called "Ghent" Azaleas. Just as Rhododendrons, where they thrive, are first among flowering evergreens, so are Azaleas among deciduous hardy shrubs. In the quarters where the selected seedlings are congregated, there are some marvellous flowers to be seen. A great advance has been made in the size and substance of the blossoms, some of which are now over 3 inches across. One, an almost pure white, was especially noteworthy, with flowers large enough to recall a Lily; but in the scarlet, yellow, orange, and crimson varieties also, the difference between their flowers and those of the original species from which they have been derived is remarkable. A new and interesting race is being obtained by crossing the late-flowering American species—A. occidentalis—with the garden varieties; this new race not only extends the flowering season of the Azaleas, but the lateness of the flowers allows of the better development of the young leaves, and so every truss has its beauty enhanced, nestling as it does among the tender green foliage.

Although the Rhododendrons and Azaleas, at this season especially, claim our attention most, they occupy only a part of the nursery, covering as it does some 500 or 600 acres, most of which are occupied by trees and shrubs, or being prepared for them. There is, in consequence, a splendid stock of hardy woody plants, which strike one chiefly on account of their superb health, and the uniformly high rank the species and varieties hold among trees and shrubs. There never was a keener or, indeed, a more exacting judge of a plant than the late Mr. Anthony Waterer. Nothing but what was best and hardiest could pass muster with him, and his favourable verdict was as good as any first-class certificate in the world. He never grew a thing merely to sell. It had to fulfil his requirements before it found a permanent place in his nursery.

The consequence of this is, that if a tree or shrub is seen in quantity at Knap Hill, that may be taken as a guarantee of its value. I have never seen the Blue Spruce (Picea pungens glauca or argentea) in such quantities, or more finely coloured, than here; and what adds to their value, as those who have had experience with grafted Conifers will know, is that they are all on their own roots—that is, selected seedlings. Another finely-coloured tree is the golden-leaved Elm, of which a large breadth is at its best.

The Yews are represented by innumerable specimen plants of the golden-leaved sorts, among which the variety elegantissima, with its graceful habit and distinctly-marked foliage, is prominent. A new variety, called semper-aurea, which is said to remain golden all the year round, was pointed out. A commendable mode of culture is practised with the Irish Yews; they are kept to one main stem, and thus the tying up that is so frequently necessary with Irish Yews, especially after stormy weather, is avoided.

One of the most interesting parts of the nursery is that which surrounds the old dwelling-house, and which, I believe, was the nucleus of the nursery. Here are planted some specimens of various Conifers, no doubt among the first of their kind ever introduced. A glorious specimen of Douglas Fir of the best Colorado form is (at a guess) 70 feet high, and perfectly furnished from its lead down to the branches that sweep the smooth lawn on which it stands. There are also noble specimens of the Maidenhair-tree (Ginkgo biloba), Red-wood (Sequoia sempervirens), Araucaria imbricata, &c. Not far away is an enormous tree of the Weeping Beech, spreading out its great tent-like mass of foliage. The Knap Hill nursery has long been famous for its Wistarias; the white variety, the double one, and the type of W. chinensis are here to be seen clambering over Laburnum and Pine. With the Laburnum especially the effect is charming, for, flowering together, the purple and yellow racemes intermingled make a striking combination. The fine, large-leaved Vine that colours so magnificently in autumn, and which is V. Coignetiæ or near it, is now in flower, but the plant is male. A large spreading tree of the golden variegated Chestnut (Castanea sativa aureo-marginata) is a striking feature, not only because of its size, but also for the richness and uniformity of its colour. A beautiful tree is the cut-leaved Beech (var. heterophylla or asplenifolia), here represented by a large and perfectly-proportioned specimen. Among scarlet Horse - Chestnuts, although nearly past, the variety Briotii might still be recognised as the best. The past season has been a good one for Lilacs, and although nearly over, Souvenir de Louis Späth stood out as the best dark-coloured one, as did Marie Legraye among the whites, and Madame Lemoine among the doubles. Finally, there may be mentioned two members of the Erica family which thrive here admirably. The one is the "Sorrel Tree" (Oxydendron arboreum) 20 to 25 feet high; the other being the dwarf and rare Epigæa repens, a most difficult plant at times to suit, but luxuriating here in moist soil on the shady side of a group of Rhododendrons.

The nursery is thrown open to the public during the Rhododendron season, and is visited by thousands; in fact, the flowering of the Rhododendron and Azalea appears to be somewhat analogous in the Woking district to the flowering of the Cherry near Tokio near Japan, where every man, woman, and child, makes it the excuse for a holiday. *B. Q.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

June 13.—*Present:* Dr. M. T. Masters (in the chair); Mr. Veitch, Rev. W. Wilks, Rev. C. Wolley Dod, Prof. A. H. Church, and Rev. Prof. G. Henslow, Hon. Sec.

Panax Mastersianus.—Dr. Masters exhibited a flowering spray of this plant, which appeared to be all male, which probably came from New Guinea. It has never been thoroughly described hitherto, as no flowers had been seen. Dr. Masters undertook to examine them and report upon them.

Cattleya Mossiæ.—He also exhibited a blossom of this Orchid strangely malformed, which he also undertook to examine.

Lilac with Central (Terminal) Bud Aborted.—He brought sprays to show the presence of this bud lying between two opposite fully-formed buds. It is said to be always aborted by frost; but as it is invariably the case, it would be more likely to be atrophied, in consequence of all the nourishment being conveyed to the two opposite buds.

Hemerocallis leaf diseased.—Dr. Smith reports as follows upon leaves sent to the last meeting:—"The reddish spots on leaf sent are caused by a fungus. Each spot is ¼ to ⅛-inch diameter, and consists of a patch of cavities (pycnidia) sunk in the leaf-tissue. From these tiny conidia are given off to disperse the fungus. In addition to the internal pycnidia, another form of pycnidium is formed on the surface, when a portion of the leaf with spots is kept in a moist chamber these latter also give off tiny conidia. The forms of pycnidia and their structure refer the fungus to the genus Asteroma. Farlow, in his *Host Index for U.S. America*, gives a form Asteroma lineola, the pycnidial stage of Dothidea lineola. The ascospore or Dothidea stage is not present, as far as I can see, on leaf sent."

Diseased Peach.—The following is also Dr. W. G. Smith's report:—"The fruit sent showed a large patch of fungus mycelium with conidia. Two forms of conidia occurred, by which the rot might be referred either to black spot disease (Cladosporium carpophilum), or the fruit rot (Monila fructigena). In transit the fungus spot appears to have enlarged enormously, and it looked quite unlike what one generally sees in either of the above Peach diseases. In any case it is a distinct fruit-rot, and controllable by spraying methods."

Peridermium Plowrighti (Kleb).—The following communication was received from Dr. Plowright, with illustrative specimens:—"The specimens of Peridermium sent herewith were produced by artificial culture, and afford an illustration of how easy a matter it is to unravel a mystery when one once has the clue to it. It is just twenty-five years ago since Wolff showed that Coleosporium senecionis was connected with Peridermium pini on Pinus sylvestris. This Peridermium is frequent upon the Fir-trees near King's Lynn, so that I had ample opportunity of confirming Wolff's observations. As a matter of fact, between the years 1881 and 1888, on ten separate and distinct occasions, I did apply the spores of Peridermium pini to Senécio vulgaris. Once, and once only, did I succeed in producing the uredo on the last-named plant. My non-success I attributed to some error in manipulation, and as I was engaged with other species, I did not follow the research up. Dr. Klebahn, of Hamburgh, however, set about the problem, and soon cleared the matter up. He showed that the species of Coleosporium had their æcidiospores on Pinus sylvestris, and not C. senecionis alone. The species on Tussilago Farfara, which is exceedingly common all over England, was one of the forms to which Dr. Klebahn directed his attention, and he gave the above name to its æcidiospores. The specimens sent herewith were produced by artificial culture. On October 16, 1898, a leaf of Coltsfoot, with the teleutospores of Coleosporium tussilaginis abundantly upon it, was fastened upon young Pinus sylvestris; on February 20 suspicious spots began to show, but it was [not] until April 22 that an abundant development of the Peridermium was observed. On that date the Coltsfoot leaf was still attached to the Fir, and the most abundant development of Peridermium was seen to be immediately beneath it. As this experiment was performed some 3 miles from my house, the plants were not visited so often as they otherwise would have been. On April 25 two young plants of Tussilago Farfara were infected with the above æcidiospores, and on May 13 each was found to be abundantly affected with the uredo of Coleosporium Tussilaginis; they were gathered, and are also sent herewith. I have to thank Mr. Walter Scott, of the Golden Ball Nurseries for the material employed in these cultures, and Mr. Rodgers for his assistance in looking after the plants."

Experiment No. 1243.—Coleosporium Tussilaginis placed on a young plant of Pinus sylvestris (infecting): Material wired on to the tree October 16, 1898; Spermogonia observed February 20. Peridermium Plowrighti abundantly produced and fully developed April 22, 1898.

Experiments 1264, 1265.—Two young plants of Tussilago Farfara, infected on April 25, 1899, with æcid spores of Peridermium Plowrighti from Experiment 1243, perfect uredo gathered May 15.

EXAMINATION IN HORTICULTURE, 1899.

The Annual Examination in the Principles and Practice of Horticulture was held on April 11: 165 papers were sent in.

Three hundred marks were allotted as a maximum, and all candidates who obtained 200 marks and upwards were placed in the first class. The total number was 80, or 48·4 per cent.

The highest number of marks (285) was awarded to Mr. Harrington H. Eaton, from the County Technical School, Stafford.

Those who secured 150 and less than 200 marks were placed in the second class. The number was 50, or 30·3 per cent.

Those who obtained 100 and upwards were ranked in the third class. The number was 30, or 18·1 per cent.

Five candidates, obtaining less than 100 marks, were not placed.

Comparing the results with those of the last two years, the entry has fallen from 190 (in 1898) to 165, the percentages of the number in each class being as follows:—

	1897 (184).	1898 (190).	1899 (165).
First class	48·3	45·7	48·4
Second class	29·8	32·6	30·3
Third class	15·2	19·0	18·1
Not classed	6·5	2·6	3·0

The answers were, on the whole, again very satisfactorily given, no very serious mistakes occurring anywhere. The purely botanical questions dealing with the structure and classification of flowers were generally avoided; but the physiological questions were mostly chosen, and were well answered.

It is very gratifying to report that there is again a general improvement in the department of Practical Horticulture. The candidates have more fully described the minor details; this is important. Candidates should also realise that it is only by grasping the full meaning of the questions that they may expect to obtain the highest honours. Some candidates wandered from the question and answered what was not in it, and in this way wasted time which might have been of much value near the close of the examination. These were exceptions, but it is well to allude to them. *Geo. Henslow and Jas. Douglas, Examiners.*

SCOTTISH HORTICULTURAL ASSOCIATION.

The members of the above Society made a visit to The Glen, Innerleithen, on May 27, by kind permission of Sir Chas. Tennant, a great patron of gardening. The Association, mustered by its able Secretary, Mr. R. Laird, and its genial Vice-president, Mr. Todd, was conveyed in two corridor carriages to Peebles. From thence four brakes drove the Association through Tweeddale, viâ Innerleithen to The Glen. It was represented by some sixty or seventy members and friends.

The Queen's weather on Saturday 27, being our first May-day in the North this year, the perfect arrangements and management, and the charms of Nature and art, of The Glen itself, made this one of the pleasantest and instructive outings yet held by this flourishing centre of light and leading in horticulture.

Mr. Todd's thoughtful distribution of fruit on the journey also added greatly to the comfort of the members.

Mr. McIntyre, the able head gardener, who has moulded and managed the beautiful gardens for a score or more of years, received the party at the front door, and proved a most instructive and interesting guide

The art treasures and the chief rooms in the mansion were also open to the party, under the direction of the head housekeeper and Mr. McIntyre.

Before leaving, the party were mustered in front of the fine mansion by Mr. Laird, while Mr. Todd, in his usual happy manner, proposed the warmest thanks of the Association to Sir Charles Tennant, Mr. McIntyre, and the housekeeper, amid ringing cheers.

Mr. McIntyre briefly returned thanks, expressing his pleasure in seeing so many of his friends around him, and saying how pleased Sir Charles would have been to welcome the Association had he not been in London. *D. T. F.*

KIDDERMINSTER AND DISTRICT HORTICULTURAL.

June 14.—The usual monthly meeting of this newly-formed Society, which now numbers over 150 members, was held on the above date, when a paper on the "Cultivation of border and Souvenir de la Malmaison Carnations" was given by Mr. W. H. Wilson of Moor Hall, Stourport, under the chairmanship of Rowland Hill, Esq., of The Firs, a Vice-President of the Society.

Mr. Wilson's lecture was very instructive, and contained valuable hints on the growth and general treatment of this lovely flower. During the evening the members arranged to visit the gardens of Impney, Westwood, and the Experimental Gardens at Droitwich, on Saturday, the 24th inst. *T. J. R.*

ROYAL BOTANIC.

June 21.—What is known as the Annual Floral Fête was celebrated in the Royal Botanic Society's Gardens, at Regent's Park, on Wednesday last, and from the horticultural point of view the event was not even a moderate success.

There was plenty of diversion offered to visitors in the shape of a Maypole dance, a pastoral play on the greensward, and high class military music. The gardens were also gaily illuminated in the evening.

The only exhibits of a horticultural character were made by Messrs. Barr & Sons, King Street, Covent Garden, London; A. W. Young & Co., Stevenage; Mr. J. Prewett, Rayleigh (table decorations); and Mr. W. J. Piper, Uckfield, who had some blooms of his new Rose Sunrise.

Messrs. Barr & Sons' exhibit contained a fine lot of varieties of Iris Hispanica, and other species, also Moutan and other Pæonies; and amongst hardy perennial flowers we noticed Campanula persiciflora alba grandiceps, Heuchera sanguinea, Gladiolus Byzantinus, Shirley Poppies, &c.

The exhibition of Rhododendrons, made by Messrs. Jno. Waterer & Co., see p. 411, were a greater attraction than anything connected specially with the floral fête.

Double Petunia.—Mr. Dyer, of Forest Gate, sends us two flowers of Petunia in which the calyx and corolla are normal, and with the usual five stamens. In addition the centre of the flower is filled up by a prolongation of the axis bearing numerous stamens, and a pistil with style and stigma. It seems as if the flower had started as a double flower, but altered its mind (if we may so say), and produced stamens instead of petals.

ENQUIRY.

A correspondent, "A. W. C.," would be thankful if any fellow readers of the *Gardeners' Chronicle* would kindly advise him in reference to the following matter. During the early morning and in the evening the garden is infested by swarms of very small midges, which are a positive nuisance to everybody, puncturing the skin and causing intense itching, and on some persons, including himself, raising small pustules. His employer says that instead of it being a pleasure to be out in the gardens at such times, it is a perfect misery. He says that the ground lies rather low, and there are some large trees in and around it, besides a rather wide brook running through it. Various methods have been tried, but without success.

ANSWERS TO CORRESPONDENTS.

Beetle Injurious to the stems of Asparagus: *G. Ringham.* The beetles sent are Crioceris asparagi—from their small size are very difficult to discover and destroy. But they may be shaken from the stems on to white cloths, caught and destroyed. In the autumn the decaying stems should be burnt, as the female lays her eggs upon the branches; and by mixing a little dry litter with the refuse it might be burnt on the beds, thus doing away with the risk of dropping eggs on to the soil in other parts of the garden, and destroying eggs that might otherwise be left on the beds. The insect was figured in our issue for January 8, 1870, p. 44.

Catanga: *S. W.* The name is perhaps meant to be synonymous with Cananga, of which there are three species noted in the *Index Kewensis*, all tropical. We should think the gardeners were amusing themselves at your expense, these plants not being suitable for bedding-out purposes.

Celery-mining Fly-grub: *F. S.* Carefully examine the plants almost daily, and kill all grubs seen to be mining by nipping them with the thumb-nail. Apply a quassia-wash, made with soaking ½ lb. of quassia-chips for a few days in soapsuds. It may kill the fly, and it will certainly render the leaves distasteful to it.

Clematis Diseased: *G. H.* The foliage and twigs show the presence of a fungus, which, by its mode of attack, would account for the dying-back complained of. The fungus (probably Dicoccus uniseptatum, of the late M. J. Berkeley), is present on the foliage, and in patches sunk into the stems. It will be best treated after growth is over for the season. Cut back as far as you safely can, and burn all the prunings. Wash the stems left with some strong adhesive mixture; the following recipe is used for washing stems in winter where fungi are being treated: Place 4 lb. of sulphur and 4 lb. of lime in a pan, with about 4 gallons of water, and boil slowly, stirring meanwhile, till a yellow paste is left; dissolve ½ lb. of sulphate of copper in some hot water in a wooden vessel, and add to it 1 lb. of slaked lime; mix the whole together and obtain a thick paste. When used for washing stems, a pound of the paste is mixed with every 2 gallons of hot water, and is applied lukewarm. If it be syringed on, rather more water is necessary. This may be applied two or three times during the resting season of the plant; but before the buds unfold, a spraying with a clear fungicide like potassium sulphide (½ oz. in each gallon of water), would help to wash off excess of adhering sulphur and lime. When applying the sulphur-lime mixture, it would be well to prevent much of it soaking into the soil amongst the roots. *W. G. S., Leeds.*

Edible and Poisonous Fungi of Japan: *Boston, U.S.A.* We do not know where the Japanese book on this subject is published; we have given the title of the book, its nature, and the author's name. An importer of Japanese books or manufactures would probably be able to get it for you.

Fungus: *G. Barham.* The Stinkhorn—Phallus impudicus, common in dry places in peaty, sandy soil.

Gooseberries Diseased: *A. D. & S.* A case of Gooseberry mildew (Microsphæra grossulariæ). With the berries in the condition sent, it is now too late to treat the disease on this year's crop, because Bordeaux Mixture or sulphur or any fungicide will probably stain the fruit, or, at least render it hardly fit for the market. All diseased leaves, berries, and twigs, should be removed and burnt. Where the bushes are very bad, we should not try to save the fruit, but start spraying at once with Bordeaux Mixture, or thoroughly dusting the bushes with flowers-of-sulphur; this will prevent the fungus spreading, and prepare the way for next season. A spraying with weak potassium sulphide solution (½ oz. in each gallon of water) would check the disease, and allow the fruit to be used, although it is never advisable to use fungicides on fruit nearly ready for market. The treatment for this mildew, as well as for the Gooseberry-rust is to spray at intervals with Bordeaux Mixture, Strawsonite, or potassium sulphide. The first spraying is done in spring before the buds open; it should not be omitted, and every part of the bush be wetted. After blossoming, spray again with any of the same solutions. Two or three weeks later, spray with potassium sulphide only. This course has been tried and found quite effective; if it were systematically followed by all growers, we should hear little of either of above diseases. *W. G. S., Leeds.*

"Kew Bulletin": *Forest Hill.* We believe this publication was first issued in its present form in 1887.

Names of Plants: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—G. W. C.* Richardia Rehmanni.—*E. T.* The flowers sent are those of a form of Phyllocactus crenatus, probably, of which there are many.—*A. M.* Hyacinthus comosus. — *Young Gardener.* 1, Campanula muralis; 2, Helianthemum vulgare var.; 3, Veronica sp.; 4, Helianthemum vulgare; 5, Linum grandiflorum: 6, Allium Moly.—*J. M.* 1, Buddleia globosa; 2, Heuchera sanguinea.—*F. W. W.* Abies concolor.—*A. B. S.* Silene nutans, a Salvia, a Cynoglossum, and a Primulaceous plant in fruit. This is the best we can do for you, as the specimens were quite withered. —*Slaymaker & Co.* Araujia (Schubertia) graveolens, see figure in *Gardeners' Chronicle*, September 8, 1888, p. 271.—*W. H. H.* Epidendrum alatum.—*J. K.* 1, Prunus Padus; 2, Taxodium distichum var. pendula; 3, Valeriana near officinalis.—*A. J.* 1, Saxifraga longifolia; 2, Gaultheria Shallon; 3, Veronica longifolia subsessilis.—*W. B.* Eriophorum polystachyum, the so-called Cotton-grass.—*W. S.* The Rose is Mrs. W. J. Grant.—*L. R. W.* 1, Scilla peruviana; 2, Thalictrum alpinum; 3, Erigeron speciosus; 4, Campanula Trachelium; 5, Potentilla, no flowers; 6, Lychnis chalcedonica; 7, an Eryngium; 8, Achillea millefolium; 9, not recognised; 10, Polygonum Brunonis. Why not send better specimens, and not more than six at a time?—*A. S.* Pentstemon ovatus.—*W. M.* The variegated form of the Gout-weed, Ægopodium podagraria.

Place of Business: *Scot.* You must excuse us for not giving an opinion on so serious a matter as a choice of locality to begin business, when you have no experience. Neither can we tell you the relative amount of profit obtainable from from pot-plants or fruits. It depends on so many circumstances. Get an estimate from some responsible cultivator. The cost of span-roofed houses depends on their width, height, the nature of the side-walls, style of ventilation, weight of glass, dimensions of sash, bars, and other items, but speaking roughly, they could be built for 15s. per foot run, all included except the heating apparatus. But you should obtain estimates from a few firms.

Pruning: *E. W. B.* The best book on the subject, both as regards principles and practice, is Bailey's *The Pruning Book*, published by Macmillan & Co.

Rust on Begonia leaves: *A. P.* Apply sulphide of potassium, ½ an oz. in one gallon of rain-water; or plunge them in weak tobacco-water for a few minutes. Very badly-affected leaves should be cut off the plant and burnt.

Tomato Fungus: *C. J.* The leaves are attacked with a rust, Cladosporium Lycopersi. Burn the affected leaves, and spray the plant with sulphide of potassium, ½ oz. to 1 gallon of water.
